I believe that opium is given too indiscriminately in the diarrhœas of children. It has its uses, and is

an orthodox remedy in such disorders, but it is given very frequently when other remedies would do quite as well and much better, and would produce none of the ill effects of opium.

Good nursing; removal of causes; keeping the patient quiet; regulation of the diet; improving the hygiene; reducing the temperature; removing the causes of disturbance of the nervous system, will, in the great majority of the cases of diarrhœa in children, do away with the necessity for medicines.

Original Communications.

EXTIRPATION OF THE BONES OF THE NOSE AND MOUTH BY THE USE OF THE SURGICAL ENGINE.

By D. H. GOODWILLIE, M.D., D.D.S.

(Read before the Medical Society of the County of New York, April 28, 1879.)

THE deep-seated bones of the nasal fossæ become necrosed from numerous causes. The diagnosis is in many cases quite difficult, as in all cases there is stenosis of the nostrils from thickening of the soft tissue. But, by the aid of the rhinoscope under a very strong light, and by properly constructed nasal speculum and probe, together with the general physical condition and history in each case, it can be made out.

If necrosis is present to any great amount, it will generally be observed that the necrosed material will have made excoriated tracks on the pharynx on either side of the vertebral ridge.

Sometimes one, and again both sides, may be so seen. On the side on which the greater amount of disorganized tissue flows will be found the openings to the necrosed bone. If the vomer is the only bone necrosed, fistulous openings may be discovered—often near the junction of that bone with the palate posteriorly.

In many cases, owing to extensive swelling of the parts, rhinoscopy is impossible.

Necrosed bone cannot always be felt with a probe from the anterior nares, as the fistulous openings are in the posterior nares, and open toward the pharynx.

But, should there be necrosis of the soft parts, or if the bone necrosis extends to the maxillary bones, then it may be discovered by the probe.

The causes, in the writer's experience, have been in about the following order:

1. From a morbid virus in the system, in which syphilis stands most prominent, struma, diphtheria, etc.

2. From mechanical and traumatic causes; polypi, causing by their growth pressure and consequent necrosis; foreign substances, deviated nasal septum, blows upon the nose, etc.

In the nasal lesions in tertiary syphilis, the necrosis nearly always commences in the vomer, then extends to the other bones of the nasal fossæ. The first symptoms are an intense pain in the frontal sinuses, extending down the bridge of the nose, and, when the disease has extended to the hard palate, pain in the mouth, in the centre line of the palate.

Treatment.—When necrosis has been recognized, no time should be lost in removing it. The dissolution and discharge of a necrosed bone may cause the loss of the surrounding hard and soft parts. It will be

necessary to give constitutional treatment suitable to each case. In December, 1872, the writer devised and made use of single and multiple revolving knives, saws, and trocars for operations upon the hard and soft tissues of the mouth and nose, the revolving power being supplied by the *surgical engine*. This consists of a fly-wheel, set in motion by the foot, a driving-pulley, and a communicating cord. On the top of the upright movable shaft the pulley is connected to a flexible wire cable inclosed in a flexible sheath. This cable is connected to the hand-piece, in which can be put any revolving instruments. The flexibility of the wire cable allows the instrument in the hand-piece to be freely used at any angle. The hand-piece, held in hand as you hold a pen, is under perfect control. The instruments are securely fastened in the hand-piece by means of a spring-catch.

The *single revolving knife* (Fig. 1) is circular and

FIG. 1.

sharpened on the edge (a), and has a protecting sheath (b) to cover up the part of the knife left exposed.

Under a velocity of two or three thousand revolutions per minute, the single revolving knife, in cutting soft sensitive parts, gives little or no pain.

The *multiple revolving knives* (Fig. 2) are arranged around the end of a shaft in an acute angle, and cut

FIG. 2.

as they revolve, and do not *scrape* as the dental burrs. These instruments have a protecting sheath (Fig. 3), to be used when necessary.

FIG. 3.—Knife (a) within the sheath.

Saws, like the single knives, are circular, and have teeth on the edge.

The *trocars* are of different forms and sizes, and

FIG. 4.

they are intended to make an opening and then to enlarge it. Fig. 4 shows two of the most efficient

ones: the spiral cutting edge, and the other flat, with two straight cutting edges and double edges on the point.

Self-retaining nasal speculum (Fig. 5) represented in THE MEDICAL RECORD, July 31, 1875. The writer has

FIG. 5.

several modifications of it to more effectually show the posterior nares.

Oral speculum described in the Transactions of State Medical Society, 1877, and consists of hard rubber or metal splint (b, b), covering upper and lower teeth, attached at their posterior ends by an adjustable hinge

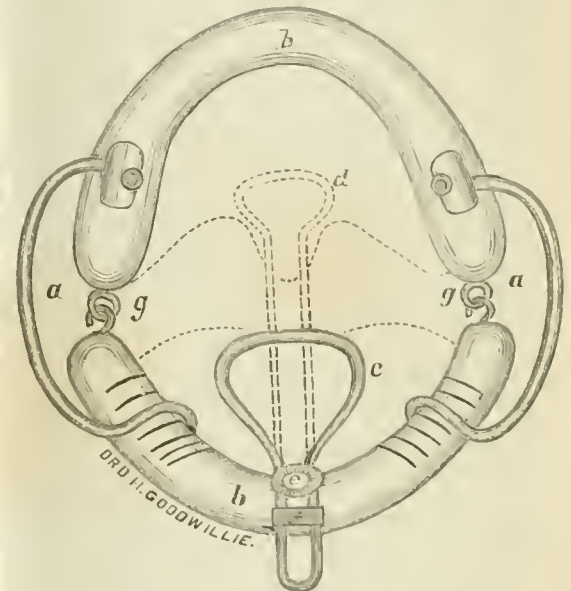

FIG. 6.

(g, g). The splints are separated and the mouth kept open by a brace (a, a) on either side. The palate spatula (d) is attached

to lower splint, the other end holding the palate against the pharynx. The *head-rest* fits the back of the head and neck, with side-pads, over these, and over the brow of the patient passes a leather strap, firmly confining

the head. (See *N. Y. Med. Jour.* for July, 1872, page 22. Resections of maxillary bones without external incision.)

Operation.—The patient is placed in an operating-chair, nitrous oxide is given to produce anesthesia, and then ether is used, and the head securely fixed in the head-rest. If the operation is in the nose, now close off entirely the nasal pharyngeal opening by pushing the uvula and soft palate back against the pharynx by means of the palate spatula, which is attached to the oral speculum. This will prevent the necrosed portions of bone thrown from the revolving knives from entering the larynx. Where the operation is

done without an anæsthetic, this preventive measure is not necessary. In the operation for the removal of the vomer, the knives are used to remove the anterior part of the necrosed bone (Fig. 7. shown by dotted

FIG. 7.

line), and then the posterior part grasped with the forceps through the anterior nares.

This is pulled out from between the soft walls covering this part of the bone. When moved from its bed, it is either brought out through the anterior nares, or, if too large to pass there, it may be passed through the posterior nares. By the careful removal with the forceps of this posterior half of the vomer, the soft parts remain, and thus the union between the septum and palate is not destroyed. Have noticed in some cases a partial reproduction of that bone. In the case of the turbinated bones, they are entirely removed by means of the knives. The hard palate and maxillary bones can all be removed without disturbing in the least the soft parts. From a sinus big enough to admit the instrument can be successfully removed any amount of necrosed bone.

Before the patient recovers from the anæsthetic, and before the oral speculum is removed, the nasal cavity is syringed out with cold water, and cleared of all necrosed bone and blood. When sufficiently recovered from the anæsthetic, remove the speculum and unstrap the head. If the necrosed portions are too large to pass out of the anterior nares, let the speculum remain until the patient has regained consciousness, and then remove through the nasopharyngeal passage or through any breach that may be made into the nasal cavity from the mouth.

The writer never makes use of sponges on cut surfaces in either mouth or nose, but makes use of anti-septic paper; or, if there is any hemorrhage from small vessels, it may be arrested by applying styptic paper. Have never yet had any secondary hemorrhage.

The writer has made use of the surgical engine for the successful removal of adhesions of the soft palate against the pharynx, nearly closing up the nasopharyngeal passage. It has been successfully used in trephining the antrum, mastoid cells, exposing the superior and inferior dental nerves, opening abscesses, resections of the jaws, removal of epulis growths. Indeed, in many other surgical operations on any part of the body, it can be most efficiently used.

CASE I.—Mrs. C. T., aged thirty-five years; born in New York; married November 25, 1868. Up to this time quite healthy. Four months after marriage had syphilis, for which she received treatment by her family physician. Up to present time has had four births. Her first child still-born at six months; second child born at full term and lived a week; third child still-born at eighth month; fourth child born at full term and lived ten months.

In 1872, had syphilitic laryngitis and was salivated. She came under my care in November, 1874. On ex-

amination I found necrosis of the vomer, lower portion of the ethmoid, vault of the hard palate, and inferior turbinated bones of both sides, and alveolus of the intermaxillary bone. There was a hole in the hard palate a half-inch in length. Front teeth quite loose from necrosis of the maxillary bone. These were at once removed. Rhinoscopic examination very difficult to make, as the uvula and soft palate were much swollen. Large ulcers on the pharynx. To combat the specific poison the patient was put upon iodide of potassium, two grammes, and increased to four grammes a day, with tonics and nourishing food.

April 29, 1875, operated for the extirpation of the necrosed bones. There were present, Drs. A. C. Post, J. T. Darby, Leonard Weber, L. B. Bangs. All the necrosed bones were removed by the revolving multiple knives through the opening in the palate and through the nostrils. The necrosed palatal vault, both inferior turbinated bones, and a small portion of the vomer, were removed through the opening in the palate; through the nostrils, all the necrosed portion of the maxillary bone and the anterior portion of the vomer and ethmoid.

The posterior portion of the vomer was now seized with the forceps and removed. By this means the soft parts covering the vomer were left intact, so that by a rhinoscopic examination the posterior part of the septum was seen as before the operation. In this case there appeared to be a reproduction of bone in this part of the vomer, and to some extent of the hard palate.

A few days after, removed by the knives some small necrosed portions of the intermaxillary, after which the parts healed rapidly. The voice somewhat nasal in tone until the opening in the palate was closed.

In October, 1875, about six months after the extirpation of the necrosed bones, uranoplasty was performed for the closure of the opening in the hard palate, which was now three-fourths of an inch in length. After removing the mucous membrane from edges, an incision is made on each side of the fissure through the soft parts and newly formed bone of the hard palate.

The soft parts were cut through by means of a galvano-cautery knife, and so had no bleeding. The bone is now pierced by the drill, and the bone separated by a chisel after the method of Sir William Ferguson; or it may be sawed through, and then they are sprung together and the fissure thus closed. In this case four horse-hair sutures were used to hold the flaps together.

These side-incisions must be kept open by packing them, or removing the granulations each day, to prevent healing until the edges of the fissure are united. A gutta-percha splint is now fitted and worn over the palate. This prevents the food, fluids, and air from causing disturbance to the healing process.

I present wax models of this case taken from casts of it before, during, and after completion of the operation.

It will be seen that the external appearance of the nose has not altered in shape, notwithstanding the nasal septum and bony palate, upon which it rests, are gone. Have never seen the nose fall in except when the cartilage or nasal or maxillary bones were involved—in other words, the bridge of the nose.

CASE II.—Mrs. F. C., aged twenty-one years, born in New York State, was sent to me by Dr. J. Marion Sims. She was married in 1865; then quite healthy; has had three still-born children, and one now living.

In January, 1872, had inflammation of the brain, which was afterward followed by inflammation of the bowels. In 1873 had severe neuralgic pains on the

bridge of the nose, centre of the hard palate, and left side of the face. This was followed by a swelling in the centre of the hard palate, and all the upper teeth were extracted. In December, 1873, when she came under my care, her condition was as follows: Her physical powers were very much reduced; constant pains in her head; a hole in the left canine fossa; great discharge from the nose and mouth. By rhinoscopic examination, and by a probe through the hole in the canine fossa, I discovered necrosis of the nasal septum and turbinated bones of both sides.

The specific origin of disease being recognized, she was put upon iodide of potassium, tonics, cod-liver oil with phosphates. December 26th, as there was a good deal of pain and swelling of the nasal septum, it was lanced, and bled freely and gave her great relief. January 4, 1876, lanced the nasal septum again. February 3d, periostitis of the left nasal bone externally appeared; applied a leech. February 4th, swelling and pain gone. February 9th, patient having improved in strength, but still suffering intense pain, removed all the necrosed bone by the revolving knives. In this operation removed the vomer, lower portion of the ethmoid, inferior and middle turbinated, maxillary walls of both right and left antrum, and a good portion of the hard palate. Present, Drs. George A. Peters, E. L. Keyes, F. R. Sturgis, and G. H. Fox. February 10th, found the patient going about the house attending to some of her household duties; no pain since the operation. February 13th, removed small pieces of the intermaxillary bone. March 6th, had some swelling of the left side of the nose, extending under the eye.

Feeling herself so much better after the operation, she had neglected to take the potassium as ordered, and this is the penalty of such disobedience. Ordered a leech and increased the dose of the iodide of potassium to four grammes per day. March 8th, swelling very much reduced and pain nearly gone. March 10th, pain and swelling gone. There was a small amount of pus on the left side of the nose, which was drawn away with the aspirator. April 10th, patient expresses herself as being nearly well. Iodide of potassium reduced to two grammes every other day. Cod-liver oil to be continued. June 23, '76, patient now quite well, and by a rhinoscopic examination no discharge was discovered. There now only remains the opening of the canine fossa to be closed.

CASE III.—*Necrosis of turbinated bones from scrofula.* Miss E. J. A., aged twenty-years, has had discharges for some time. Smelling much impaired. On examination discovered that both middle turbinated bones were necrosed. Considerable bulging of the nasal septum to the left side, which, her mother says, came from a fall in childhood. Removed the necrosed turbinated bones with the revolving knives, while she was under anesthesia produced by nitrous oxide. After a month's treatment the parts healed, respiration free through the nostrils, and she was discharged.

CASE IV.—The following case was brought to me by Dr. Leonard Weber, of this city: William H., of New York, aged thirty-two years, with syphilitic necrosis of the bones of the nasal fosse. His condition was found as follows: Small hole through the hard palate one half inch in length; four fistulous openings above the alveolus, at the left central incisor, on each side of the left canine, and above the first molar of the same side. Some teeth were extracted on this side; the sound and firm teeth were allowed to remain.

In the presence of Drs. L. Weber, C. C. Lee, R. P. Lincoln, T. R. Pooley, H. G. Fox, L. Spannhake, and

E. C. Lining, U.S.A., there were removed through the opening in the palate, and through the nostrils, the hard palate, vomer, inferior turbinated bones, cancelled portion of the left maxillary and intermaxillary bones.

The posterior portion of the vomer was dislodged and removed by the forceps, without separating its covering from the palate. In these extirpations there has never been any great amount of bleeding, and have never yet had to resort to the tampon. The styptic action of the paper controls all bleeding from the small vessels. There was much thickening of the soft parts, just inside of the vestibule of the nostrils; and as it interferes with free respiration, it was removed by means of the galvano-cautery. A protecting shield is put into the nostril, the top part of which incloses the part to be cauterized. The white-hot cautery wire is applied through the shield to the part exposed at the top of it.

CASE V.—H. W. B., from Otsego county, New York, had catarrhal difficulty when a child. Has had polypi removed from right nostril by family physician. In July, 1876, the writer removed a large polypus from right nostril, attached by a large pedicle to upper part of vomer. From pressure the left middle turbinated bone had been lost, and from the same cause the vomer was pushed to the left. The right inferior turbinated was forced down into the inferior meatus. There were three bends in septum. The greatest bend was in the posterior and upper part of the septum; the lesser bend in the cartilaginous septum. The whole septum had also a very sharp bend, with hypertrophy of the bone along the line of, and bending into, the inferior meatus. This, with a pushing downward by the growth of the inferior right turbinated, produced complete stenosis of that nostril. This warping of the septum into the inferior meatus probably commenced with his trouble in childhood. This condition of things prevented the free discharge of mucus from the nostrils. In September, '76, removed with the nasal punch a portion of the bend in the cartilaginous septum. When I saw him again in May, '77, the upper part of the vomer had necrosed and passed away, the lower thick hypertrophied part was removed under an anæsthetic. The multiple knife, armed with a shield, passed through the inferior meatus, cutting its way through to the pharynx. The inferior turbinated bone was also removed. This gave a clear passage for the escape of the mucus and free respiration.

The most common local application used in these cases is a powder consisting of iodoform and camphor, each four grammes, subnitrate of bismuth, thirty-two grammes, blown into the nostrils with several pounds' pressure, so as to reach every part of the nasal cavity. To do this efficiently the powder must be impalpable, the calibre of the blower small, and applied with considerable force of air, the parts to be thoroughly cleansed with salt and tepid water by means of a syringe, and then the powder applied through the anterior nares.

CALOMEL IN ECZEMATOUS AFFECTIONS.—Dr. H. E. Dykeman highly recommends the following in indolent secondary syphilis, particularly when cartilaginous regions are attacked in eczematous affections, and in pruritis vulvæ:

R. Hydrag. chlorid mit. grs. xxx.

M.

INFLAMMATION OF THE FRONTAL SINUS, ABSCESS, AND FISTULA.

By CHARLES STEDMAN BULL, A. M., M. D.,

SURGEON TO THE NEW YORK EYE INFIRMARY.

Owing to the somewhat intimate connection between the cavity of the nose and the frontal sinus, which exists through the prolongation of the nasal mucous membrane through the infundibulum to the sinus on either side, catarrhal inflammation of these sinuses is a very common accompaniment of naso-pharyngeal catarrh. Though it may occasion a great deal of discomfort, and even actual pain, yet the inflammatory process usually passes off, as does the nasal catarrh, without producing serious disorganization, though leaving behind a tendency to its recurrence, which increases with every relapse. Serious inflammation, resulting in the formation of pus, would here, however, very naturally cause a distention of the sinus, and, owing to the extreme narrowness of the passages between frontal sinus and nasal cavity, an abscess would form, caries of the bone would occur, and a perforation through the skin would lead to the formation of a fistula of the most obstinate and annoying kind.

The inflammation of the mucous membrane lining the sinus may be acute or chronic, and in rare cases leads to the formation of pus. The symptoms are often very obscure, and the differential diagnosis very difficult, owing to the fact that the symptoms may so closely simulate those of orbital disease. The abscess may open through the skin before a diagnosis is made. If the external swelling extends lower down in the lid, so as to reach the internal ligament in front of the lachrymal sac, it may be mistaken for distention of the sac, though usually the latter is a softer swelling.

There is sometimes considerable deformity from displacement of the eyeball downward and outward. The external opening usually occurs in the upper lid, near the superior border of the tarsus; and if the abscess continues discharging, the lid becomes adherent to the orbital margin at the point of the opening in the sinus, and the mouth of the fistula is retracted. If proper treatment is not resorted to, extensive caries of the frontal bone in the vicinity is very likely to occur, the dead bone coming away in small flakes.

The proper treatment consists in making a communication between the abscess and the cavity of the nose, so that, by continuous drainage and the use of either caustics or astringents, the discharge of pus may cease and the cavity eventually fill up. If the abscess have not opened externally, make an incision through the skin, over the most prominent part of the swelling, and evacuate the contents. Usually the antero-inferior wall of the frontal sinus will be found either entirely absorbed or reduced to a mere shell. Then enlarge the opening and explore the sinus thoroughly for dead bone. Put one finger in the sinus, and the little finger of the other hand in the corresponding nostril, so as to find out how near the fingers may be approximated, and thus learn how far the destructive process may have extended. If the intervening bony division is found to be thin, it should be divided by a small gouge, working from the sinus downward and inward, and, a communication having been established, a small rubber drainage-tube, suitably pierced with holes, should be introduced. This serves the double purpose of keeping the channel open and of enabling the surgeon to wash out the

sinus and nose. When this has been done, and all particles of dead bone removed, the suppurative process diminishes very rapidly; and when the drainage-tube is removed, the external fistula closes of itself, though occasionally it may need to be stimulated, either by freshening the edges or by one or two applications of some caustic agent.

The following case is a typical one of its kind, and, as the disease is a rare one, the history will be given in full.

CASE.—The patient was a young man, *æt.* 25, an officer in the merchant marine, who had been troubled for years with naso-pharyngeal catarrh, which had affected the middle ear and caused deafness, for which he had been treated. The catarrh remained, however, and his attention was directed to his present trouble, three years before I saw him, by a severe pain over the right eye, just below the eyebrow, which lasted a week or ten days, and was followed by a swelling in the same place. This occurred in the course of an acute attack of naso-pharyngeal catarrh. This swelling he could cause to disappear by pressure, and then the contents seemed to escape by the right nostril. These symptoms have recurred again and again, and sometimes the swelling was so great as to close the right eye. Three months before I saw him the swelling had recurred, opened externally with great pain and redness of the skin of the lids and forehead, and a large quantity of pus discharged. Since then the abscess has never closed, but a small amount of offensive pus is discharged constantly, and occasionally small particles of bone have come away. There is a fistulous opening through the upper lid, just beneath the edge of the orbit. The mouth of the fistula is adherent to the orbital margin, and a probe introduced passes upward, backward, and inward to the depth of an inch and a quarter.

An incision was made parallel to the orbital margin with a strong scalpel, for about an inch in length, which easily broke through the thin shell of bone which was left. The lips of the wound were then held apart, and the cavity carefully and gently syringed with warm water. Some pus and a few small scales of dead bone came away with the water, but none passed down into the nostril. An examination of the frontal sinus then showed an eroded condition of its bony walls, with, however, no very extensive caries. A second use of the probe broke through a slender bony partition near the median line, and a stream of water injected into the sinus trickled out of the nose. The cavity was so small that it was thought best not to introduce a drainage-tube, but to introduce a tent in the external wound in order to keep it open, and trust to natural drainage. Directions were also given to syringe the sinus twice a day gently with warm water and a few drops of a saturated solution of potass. permangan. Under this treatment the purulent discharge rapidly subsided. What dead bone came away was in such small particles as were not recognizable, and in a little more than six weeks the sinus and fistula had both closed, without any further interference. The lid, however, remained attached to the orbit at the seat of the former fistula, and this interfered somewhat with its motility, though not to any very disturbing extent.

COLUMBUS MEDICAL COLLEGE.—Certain minor chairs in this institution have been abolished and their duties placed upon the original ones to which they were subsidiary. It is intended that this change shall make the course less cumbersome to the student and more thorough.

JABORANDI IN THE TREATMENT OF PUERPERAL ALBUMINURIA AND CONVULSIONS.

By EVERETT S. WARNER, M.D.,

LATE HOUSE PHYSICIAN IN BELLEVUE HOSPITAL, NEW YORK.

In the Record of March 1, 1879, are reported six cases of puerperal albuminuria treated by jaborandi. Of these, four had convulsions. Five out of the six cases died, and of those which had convulsions none recovered.

The doubt in many professional minds—which such unfavorable reports increase—as to the usefulness of jaborandi as an eliminative agent, induces me to offer the following case of puerperal eclampsia, in which its administration was certainly most beneficial.

The patient was a primipara, *æt.* 22, six and a half months pregnant. For several days she had suffered from headache and epigastric pain, with vomiting, and had passed only a small quantity of urine. During the twenty-four hours previous to the attack these symptoms became greatly aggravated.

When I first saw her, 9.30 P.M., June 4th, she had just emerged from the third convulsion, the first one having occurred late in the afternoon of the same day.

The patient was sleeping heavily, but on awaking appeared confused and excited. Temperature (axilla) 101½. Pulse regular and full at 90 per minute. Skin hot and very dry. There was slight œdema about the ankles. Pupils dilated, but no disturbance of vision. Auscultation of anterior surface of the chest negative. Patient complained bitterly of headache. Every few moments she vomited distressingly, the vomiting being accompanied with severe epigastric pain. The fetal heart could not be detected, but movements of the child were distinctly felt. The bowels had moved during the day. The urine became solidified by heat and nitric acid, and this, after standing for thirty-six hours in the test-tube, showed only a thin layer of fluid above the mass of albumen. Hyaline casts only were discoverable, and these were in great abundance. Administered ℞. xv. fluid ext. jaborandi hypodermically. In about twenty minutes the skin became a little moist. Soon after repeated the dose, and in a few moments the diaphoresis was considerable—not excessive—attended with slight increase in the salivary secretion. Also ordered oxalate of cerium, grs. iij., q. 3 h.; poultices to the epigastrium, and cold applications to the head. After the first dose of oxalate of cerium the vomiting ceased, and was not renewed except once on the following day, when it lasted for a moment only. Within an hour after giving the jaborandi I left her sleeping naturally.

On the following morning, June 5th, found she had passed a comfortable night, sleeping most of the time. Pain in the head was much relieved. Epigastric pain nearly gone. Temperature 101°. Pulse still regular and full. Four ounces urine discharged during the night. The sweating, which had been encouraged by abundant coverings, continued until early morning. As the skin was now again rather dry, gave ℞. xv. of the fluid extract hypodermically, which resulted in slight perspiration. Continued the oxalate, and in addition gave *inf. digitalis* ʒij. with *pot. acetate*, grs. xv., q. 3 h., and applied dry cups over the kidneys. Eight ounces urine passed during the day.

There were two convulsions during the day—one at

10 A.M. the other at 4.30 P.M.—which were controlled by chloroform. The non-viability of the child, the anxiety of the parents for its life, and the improvement in the condition of the mother, together with the fact that the existence of the child had been determined on the previous day, had prevented the induction of labor.

The next morning, June 6th, uterine contractions began. An enema was given and the os partially dilated by the fingers.

Labor terminated in four hours. The fetus had evidently been dead for only a short time.

The last convulsion, which was long and severe, occurred three hours after delivery of the child. I saw her soon after it. She was tossing uneasily about the bed. The condition of the pulse did not warrant the further administration of jaborandi. Gave ℞. ix. Magendie's sol. morphia by hypodermic injection.

June 7th, morning.—Patient slept well. Passed about twelve ounces of urine during the night, fifty per cent. of which is albumen. Casts are less numerous. The digitalis and acetate of potass., discontinued on the previous day, are again renewed.

From this time patient rapidly improved; the urine increased to more than normal quantity. Albumen and casts gradually grew less, and now, June 16th, twelve days after the attack of convulsions, the urine is normal and patient is allowed to sit up.

Had the usual dose of jaborandi or its alkaloid, pilocarpine, been given in this case, I doubt very much whether it would have progressed so favorably.

From the numerous cases, chiefly of Bright's disease and principally in hospital practice, in which I have watched the effect of the drug, I can but believe that the ordinary dose—ʒi. of the fluid extract—is, as a rule, by far a too large, and in many cases a dangerous quantity to administer.

A case was admitted, last winter, to Bellevue Hospital, suffering from acute Bright's. The skin was hot and dry; pulse strong and regular; temperature considerably elevated; auscultation of the chest negative. I immediately gave ʒi. fluid extract jaborandi by mouth. Within an hour, while in a most profuse perspiration, the patient was suffering from extreme dyspnœa, with bronchial and tracheal râles.

The case terminated fatally in a few hours, death apparently being due to suffocation, as the action of the heart continued good until near the end. The autopsy showed œdema of the lungs, with a large amount of fluid in the bronchi. Jaborandi increases the bronchial secretion, as the frequent development of abundant râles, soon after giving it, proves. This increase is sometimes so great as to prove a serious obstacle to respiration. May not jaborandi also cause transudation of fluid into the pulmonary air-cells?

Obstructed respiration and failure of the heart's action seem to me to be the dangers especially to be feared in prescribing it. By giving the drug in small doses the patient is not subjected to these dangers; at the same time considerable diaphoresis is produced, with but slight salivation.

By no other means can sweating be brought about so quickly, easily, and with less discomfort to the patient. ℞. xv. of the fluid extract, or the equivalent in pilocarpine, should be given either by the mouth or hypodermically, and this dose repeated every half-hour until moderate perspiration is induced. By keeping the patient well covered, diaphoresis will continue for several hours.

Reports of Hospitals.

JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

(Reported for THE MEDICAL RECORD.)

CYSTITIS IN THE MALE.

If there is acute pain and spasm, blood is taken from the perinæum by means of leeches. The patient is kept in bed, and hot fomentations are applied over the pubes. At the same time he takes demulcent drinks with a little hyoscyamus. If the pain be violent, morphia is given by the mouth or rectum.

The following prescription is frequently employed :

R. Pulv. opii..... gr. xij.
Camphoræ..... gr. xxx.
Ext. belladonna..... gr. iij.
Cacao..... q. s.
M. et in suppos. No. vi.; divide.

S.—One each night before retiring.

The diet employed is bland and unstimulating.

After the acute symptoms have abated, balsam of copaiva is given thrice daily in capsule, or rubbed up in an emulsion. To this opium is occasionally added to prevent flatulence and griping. Turpentine in capsule is used with advantage in some cases. Other remedies are sometimes employed—such as buchu, decoction of trailing arbutus, or uva ursi with hops, highly recommended by Sir Henry Thompson—uva ursi, f 3 iss., lupulinae, ʒ i., aquæ, Oij. This mixture is allowed to simmer for two hours; then enough water is poured in to bring the quantity of the mixture up to two quarts, and then two grains of morphia and two drachms of the bicarbonate of sodium are added. The dose of this mixture is a wineglassful.

In some cases benzoic acid is found very useful. The initial dose is five grains, and the quantity is then gradually pushed up to thirty grains, and, in some instances, as much as one drachm is taken thrice daily.

A prescription very often employed by Dr. S. W. Gross and other members of the hospital staff is the following :

R. Copaibæ balsami..... ʒ iv.
Acid. benzoici..... ʒ iv.
Gummi arabaci,
Sacchari, añ..... ʒ ij.
Gaultheriæ olei..... gtt. xx.
Aque camphoræ, q. s. ad..... f ʒ viij.

M.

S.—A tablespoonful every four hours.

As regards the treatment of the urine, the first thing that is done after dilating the stricture, if one exists, is to wash out the bladder. This is usually done in the following manner: A gum elastic bag, holding about four ounces, is procured, and a basin full of water at 98° is made ready. Then, after drawing the urine with a flexible catheter, whose end is smooth, the bladder is washed out by simply connecting the mouth of the bag with the catheter, which has been allowed to remain *in situ*. The warm water thus injected is retained as long as possible, then drawn off, and the operation repeated.

If the urine is fetid, one grain of the permanganate of potassium, or a small part of carbolic acid, is

added to each part of warm water. When the water comes out clear, if it is desired to make an impression upon the mucous membrane of the bladder, a solution of borax (fifteen grains to the fluid ounce of water) is injected. At other times a twenty-grain solution of the nitrate of silver is employed. If this solution does not cause too much smarting it is allowed to remain ten seconds in the bladder.

The patient is kept at rest in bed during this treatment, and placed upon a very bland diet. (If there be any pain after the warm-water injections have come away, a little morphia is thrown into the bladder, and allowed to remain there; or, if this does not afford relief, a hypodermic injection is given).

In some bad cases it is necessary to perform cystotomy, or colotomy, in order to bring about a free discharge of fluid from the bladder.

Patients with cystitis are warned not to ride in wagons over rough stones; if possible, to refrain altogether from riding. They are advised to avoid all stimulating drinks, and to always wear flannel next their skin. They are not allowed to eat any greasy food, but are allowed plenty of fish and oysters. Their bowels are kept open by cold-water injections, or saline cathartics.

TINEA FAVOSA.

The hair is first pulled out by the roots, the parasites killed and the scabs poulticed. Before beginning to pull out the hair, however, the whole head is closely shaved. The separate hairs are pulled out with delicate tweezers. These hairs are pulled out in their long axis, otherwise they would be liable to break off short. The poultice is applied immediately after the hairs are pulled out, so that the pustules may be well softened. After applying the poultice some parasiticide—such as the iodide of sulphur, or the bichloride of mercury—is rubbed in. The parasiticide most frequently used by Dr. J. Solis Cohen is that formed by adding gr. ij. of sulphur iodide to ʒ i. of lard.

EXTERNAL HEMORRHOIDS

are treated surgically by incising the pile with a bistoury, and then pressing out its contents, viz., the contained clot of blood. This slight operation relieves the pain and tension at once. As an after-treatment the parts are well bathed with cold water, and some medicine given to act on the liver and bowels. Dr. Samuel D. Gross does not at all believe in the immediate removal of these growths with the knife, as recommended by Erichsen and Bryant.

NÆVUS MATERNA.

Two oiled pins are pushed right through the base of the growth so that they cross each other at right angles. A groove is then cut all the way round between the points of entrance and of exit of the pins with a sharp knife. A stout ligature is then passed round the base of the nævus and underneath the pins, and is drawn so tight as to completely strangulate the growth. Dr. S. W. Gross does not believe in temporizing in these cases by the use of the cautery or by the injection of irritating substances into the body of the tumor.

TAPPING IN DROPSY.

Dr. J. Solis Cohen treats obstinate cases of dropsy of the legs by tapping. The minute trocars which he uses are made of gold, with openings at the ends and on the sides. They have sharp three-cornered points. In inserting these canulæ they are thrust well into the flesh from below upward and then fastened in posi-

tion by strings tied to their bulbous extremities. These strings are fixed by pieces of adhesive plaster. When the canule are fixed in position, slips of rubber tubing are fastened to their bulbous extremities. Where the fluid does not flow freely after the canula is inserted, its flow is started by pulling the rubber tubing between the fingers pressed tightly together and so creating a vacuum. Care is had not to insert the canule too far down in the limb, where their presence may produce a sore owing to the weight of flesh above them.

ACNE ROSACEA.

Dr. F. F. Maury treats this condition by the local application of a mercury plaster. The alimentary tract is kept thoroughly open by a methodical course of salines, such as epsom and Glauber salts, and Crab Orchard and Hunyadi János water.

In addition to the mercury plaster as a local application, the following lotion was ordered for the face:

R. Sulphuris sublim..... ʒ ij.
Etheris ʒ ij.
Vini frumenti..... q. s.

Fiat lotio.

The patient was advised not to drink anything but a little red or white wine, and to be careful to refrain from fish and too much meat.

DILATATION OF THE STOMACH.

The endeavor is made to produce contraction of the walls of the stomach by washing out the ingesta with the stomach-pump, and then rinsing out the stomach with a solution of some disinfectant. The double effect is thus had of cleansing and gymnastic exercise. In inserting the stomach-pump the head of the patient is turned back, and the tube is passed down the œsophagus over two fingers placed in the mouth as a guide. This treatment by the stomach-pump is persevered in for a long time. The stomach is well rinsed out at each sitting. To get rid of remnants of food-ferments are employed. The patient's general tone is sustained by tonics.

PROSTATORRHEA WITH STRICTURE.

Where the stricture is fibrous, it is gradually dilated by means of Dr. S. W. Gross's expanding bougie. Where it is spasmodic and due to hyperæsthesia of the urethra, it is treated by the persevering introduction of conical steel bougies of gradually increasing sizes. If the meatus is unusually small it is slit up.

In obstinate cases of this nature astrigent local applications are necessary, such as nitrate of silver, which is applied by means of the *porte caustique* devised by Prof. S. D. Gross. The solid nitrate is the form of silver used. After applying the caustic the patient is kept in bed, his diet reduced, and demulcent drinks administered freely.

If there be constipation, the bowels are kept well open by means of an occasional purge, or the patient takes as a routine medicine, each morning before breakfast, fʒ vi. of Hunyadi János water, or the following prescription, which was first originated by the late Dr. Robley Dunglison:

R. Mag. sulphat..... ʒ j.
Potass. bitart..... ʒ j.
Ferri sulphat..... gr. x.
Aquæ..... q. s. ad ʒ iij. M.

S. A wineglassful every morning before breakfast.

Another excellent plan which is often pursued is to inject five or six gobletfuls of cold water into the rectum each morning.

The diet provided is nutritious but bland. No coffee, tea, malt or alcoholic liquors, and no greasy or fried foods, are allowed.

For breakfast he is given grits or oatmeal, meat, and bread and butter; for dinner plenty of good rare beefsteak or mutton-chop, with potatoes, tomatoes, etc. Supper should be a light meal.

If there be any anæmia, something like the following is given:

R. Quinæ sulph..... gr. xl.
Tinct. ferri chloridi..... fʒ iv.
Tinct. nucis vomicæ..... fʒ ivss.
Aquæ..... q. s. ad fʒ iijss. M.

S. A teaspoonful four times daily in water through a siphon.

If, on the other hand, there be a tendency to plethora, depressants and purges are employed. The patient takes a sitz-bath every night and morning. He sleeps on a hard mattress, empties his bladder thoroughly before going to bed, and uses only the lightest of coverings.

To keep down the venereal appetite thirty grains of the bromide of potassium are given three daily.

Where the condition is obstinate, local blistering is resorted to. A camel's-hair brush is dipped in cantharides and collodion, and a couple of lines are drawn with it first on one side of the raphé of the perineum, and then on the other.

Intercourse is had regularly so that the distended seminal vessels may be relieved, but it is never had at shorter intervals than every two or three weeks.

Where there is functional disease of the heart with palpitation, and flushing of the face, there is nothing better than digitalis in small and long-continued doses. It may be given in any of its medicinal forms.

PARALYSES OF THE RECURRENT LARYNGEAL NERVE.

Nerve tonics, such as strychnia, phosphorus, iron, and cod-liver oil, are used. In the so-called instances of hysterical and nervous aphonia, a sponge-probang is moistened and brought into contact with the vocal cords, which are thus thrown into a state of spasm and so brought together. The same effect is produced in other cases by sprays of ether projected upon the part, or by inhalations of pungent substances.

When all else fails, electricity is employed and is applied directly to the paralyzed muscle.

In using electricity, the plan is to place one electrode directly over the crico-thyroid ligaments outside, and then to carry the other electrode into the larynx and place its point in contact with the cords, or between them. The electrode in the throat is only kept in position a few seconds at a time. Cures are often effected in this way by a single application.

Where intra-laryngeal electric excitation is not possible, the percutaneous method is tried. This consists in passing a current from one side of the neck to the other, and so through the larynx. Or, the patient is placed upon the insulating stool and a spark is drawn from the cricoid cartilage with the knuckle.

In cases of hysterical aphonia a cure is often effected by the mere introduction of the laryngeal mirror, the patient being given to understand that this is the curative procedure.

Another method often tried is to stand behind the patient and grasp the thyroid cartilage between the thumb and forefinger, while at the same time the middle finger is placed under the cricoid cartilage, pulling it up and in front of the thyroid. In this way the vocal cords are stretched and made tense, and so caused to vibrate by means of the inspiratory current.

Progress of Medical Science.

BILATERAL NEURORETINITIS DESCENDENS IN DIABETES MELLITUS; TUMOR OF THE BRAIN.—Dr. Grossmann, of Buda-Pest, reports a case of diabetes mellitus complicated with bilateral neuroretinitis descendens, with consecutive amaurosis, in which the autopsy revealed a tumor as large as a walnut, situated at the base of the brain just anterior to the pons. The tumor was firmly adherent to the dura mater, and involved the hypophysis, the chiasma, and neighboring parts of the brain as far as the gyrus callosus-marginalis. The pia was thickened and the fourth ventricle was filled with a pseudo-membranous mass. Microscopically the tumor consisted of elements belonging to the connective tissue group, almost all the varieties of that group—from mucous tissue to dense fibrous tissue—being represented; the greater part of it was made up of blood-vessels with immensely thickened walls. It was impossible, however, to class the tumor with any of the special forms of morbid new growths. The diagnosis of sarcoma could not be made because of the varied forms of the cells and of the mode of development, the brain substance being directly involved in the new growth, and not merely pushed aside by it. It was not a glioma, because the new growth sprang from the connective tissue of the blood-vessels, and not from the neuroglia. It seemed more properly to constitute an intermediate form of tumor produced by the concurrence of vascular new growth with chronic inflammation.

During life the probable existence of a cerebral lesion had been admitted, but the direct diagnosis of a tumor of the brain was not made on account of the absence of symptoms pointing to that affection. In all probability the cerebral lesion constituted the original affection, the diabetes being consequently symptomatic of it. This view seems to be especially favored by the fact that a pseudo-membrane nearly a millimetre in thickness was found filling the fourth ventricle. The bilateral amaurosis was due partly to the direct pressure of the tumor on the chiasma and the optic nerves and tract, and not solely to the original obstructive neuritis. During life the urine had contained albumen, but as the autopsy revealed no nephritis, the pathological changes in the fourth ventricle and the neighboring parts of the brain produced by the tumor may be regarded as the cause of the albuminuria as well as of the mellituria. In the treatment of the case, Carlsbad water, carboic acid and salicylate of soda had been employed. The quantity of sugar excreted diminished under their use, but it never disappeared entirely from the urine.—*Berliner klin. Wochen.*, March 10, 1879.

CUTANEOUS BILIARY FISTULE—EXTRACTION OF NEARLY A HUNDRED CALCULI THROUGH THE ABDOMINAL WALLS.—In July, 1876, Dr. Anger, of Menilmontant, was called to see a woman, aged 63 years, whose abdominal walls were, so to speak, riddled with fistulous openings, which led into large subcutaneous cavities. The openings discharged freely a greenish yellow pus resembling the bile in color. The patient had suffered for over thirty years from violent attacks of biliary colic recurring at irregular intervals; sometimes she would be almost free from them for years, and again they would come on very frequently. In the intervals she complained almost constantly of a feeling of weight in the right side. In February, 1876, she had a series of attacks of colic, accompanied by constipation and vomiting, complete loss of appetite, tympanites, and great difficulty in

walking. In the early part of April a red and painful swelling appeared on the right side, a little above the umbilicus; this swelling soon spread over the entire lower portion of the abdomen and extended to the right leg. On April 15th the tumor broke suddenly with a noise like that produced in opening a bottle of champagne, and a jet of watery fluid with a pronounced faecal odor, escaped. On the following day her bowels moved for the first time in fifteen days. Toward the end of April several black spots appeared on the lower portion of the abdomen; these were soon transformed into fistulous openings, which gave exit to a blackish magma containing a quantity of small biliary calculi. When Dr. Anger was called to the patient he found the abdominal walls red, indurated, painful to the touch, and presenting four fistulous openings, through which the sound entered into large subcutaneous cavities. Through the upper opening biliary calculi could be felt at a depth of about five centimetres. This opening was dilated with tents of laminaria until the finger could be introduced with ease, and about a hundred biliary calculi were then removed with ordinary dressing-foreceps. The ductus choledochus was found to be almost as large as the little finger. After the removal of the calculi the fistulous canals and the cavities were freely laid open and an alcohol dressing was applied. After the operation the fever disappeared, the appetite returned, and the wounds gradually, but very slowly, healed. There has been no return of the colic since the operation, and the patient now enjoys better health than she has at any time since she was twenty-one years of age. Dr. Anger ascribes the formation of the calculi in this case to the excessive use of butter.—*La France Médicale*, April 16th, 1879.

ON THE ALBUMINATE OF IRON.—In the wards of Prof. Demarquay, in Paris, the albuminate of iron has been employed with much success in the treatment of chlorosis and of the anæmia of chronic uterine disease. Under his direction a series of experiments were undertaken to determine the absorptibility of the ferruginous preparations. The results showed, first, that the discoloration of the fæces is not proportionate to the quantity of iron excreted. Certain salts of iron which are discharged almost entirely, undergoing little modification in their passage through the intestine, do not color the fæces, while others, for example the citrate, of which the greater part is assimilated, color the fæces decidedly. Second, that the quantity of iron absorbed stands in general in a direct ratio to the solubility of the salts ingested. From this point of view of assimilation, the salts formed by combination with organic acids, such as the citrate, the tartrate, etc., and above all the albuminate, must be placed in the front rank.

In a case of extreme anæmia resulting from repeated hemorrhages that were due to a uterine polyp, the albuminate of iron rendered the most signal service. The patient was unable to retain any other form of iron on her stomach, and seemed to be almost at the point of death. The albuminate of iron was ordered in combination with the syrup of bark (*liqueur de Laprade*); the first two spoonfuls were retained with difficulty, but the third was well borne. On the eighth day the patient was able to eat solid food, and the paleness was less intense. Fifteen days later the microscope showed a marked increase in the number of red blood-globules. She was sent to the country, and in a month menstruation had reappeared, and the patient presented the appearance of perfect health.—*Gazette Obstétricale*, March, 1859.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 12, 1879.

DUTY ON CINCHONA ALKALOIDS.

THE act for removing the duty on cinchona alkaloids has been passed by both houses of Congress, and presumably will become a law. With such a state of things the medical profession is well pleased, inasmuch as the price of quinine will be reduced and the consumer will have less of a tax to pay to the manufacturers. Looking upon the question from the standpoint of its general merits, it is difficult to conceive why any opposition should have been raised against the measure. As predicted, however, several of the large manufacturers not only viewed it as a calamity, but asserted with a degree of positiveness intended to alarm the public, that they would cease to place the drug upon the market. The more direct source, however, from which the opposition emanated points very plainly to a personal interest in the taxation of quinine which can hardly be considered of ultimate advantage to the consumer. We do not see how this can be denied. For, the minority which led and sustained the opposition, and availed themselves of parliamentary tricks to defeat the bill, were too inconsiderable to weigh in the balance against the general sentiment of the House, or impress the majority of the members in favor of the few monopolists whose interests were so openly advocated.

Notwithstanding the assumption on the part of these manufacturers, it is fair to presume that they will not attempt, and cannot stop the supply.

The removal of taxation may decrease their profits, but there will still remain for them an abundance of remunerative margin for carrying on a profitable business. But, as has been intimated, suppose they do stop manufacturing the alkaloids. We believe the result will simply be that the cinchona barks they use will either remain in Europe or go directly there, and that the same quantity of the alkaloids will be accessible at lower prices. Before the tax was removed the manufacturers here were enabled to pay

higher for bark than the same would bring in Europe, and the higher prices paid here were transferred to the cost of the consumer in the product. In that manner the manufacturers here became injurious competitors with the cheap makers in Europe, without giving any adequate reason why the alkaloids cannot be made as cheaply in this country as elsewhere. It now remains to be seen whether or not the manufacturers will cease work. But if they do, we believe the law of demand and supply will furnish to the consumer all his necessities will require.

THE HOSPITAL BIBLE, FRUIT, AND FLOWER MISSION.

A FEW weeks ago there was inaugurated in East Twenty-sixth Street, which may be said to be the medical quarter of the city, a new auxiliary to the work which is being carried on by medical men in the hospitals. Certainly, medical men are the chief workers in all institutions for the care of the sick; but what would they be without nurses? What would they be without the aid of those who care for cleanliness in the wards where lie the helpless and the sick? This institution, of which we have spoken, is to be the headquarters of the mission to the sick in the hospitals; a mission which is to care, not for their necessities, but to see to it that the sick poor secure some of the luxuries of life. *We may* possibly be criticised if we continue to say, not the necessities, when it is remembered that it is a Bible as well as a fruit and flower mission. But, as medical journalists, we are obliged to leave out of account, to a large extent, the religious aspect of the mission, much as all men, who wish well for their kind, may rejoice that truth and consolation, which all appreciate, are brought to the suffering.

The object of the ladies who have founded and carry on this enterprise is to visit the sick and provide them with the delicacies which hospitals cannot furnish, and also to surround them with the fragrance and beauty of flowers. Besides this, there is religious instruction for those who are willing to accept it.

The late civil war developed many such instrumentalities for the alleviation of the sufferings of the sick, as that of which we are now speaking. Among the most useful employment of the volunteers who visited the hospitals during that period was that of letter-writing for the patients. Nurses are proverbially overworked, and letter-writing in their hands is either hastily or poorly performed, or not at all. At the outset of our commendation of what the ladies of the Fruit and Flower Mission are doing, we would venture to suggest to them for their consideration that they add letter-writing to their other beneficent work.

We are inclined to think the influence of mind over matter is sometimes underrated by medical men. The true physician will always be careful to favor cheerfulness in the mind of his patient. The element

of hope and faith, and the conviction that one is being cared for by some one else, sometimes do very much even to assist a fractured limb or a wound to heal, or to abate the violence of a fever. As an auxiliary, therefore, to the great work in which most of our readers are engaged—that of lengthening life and mitigating human suffering—we hail this one, which has now been through three years of existence, and which may be said to be firmly established. It should be added that these Christian ladies propose to enlarge the work they have been doing by caring for the throng of so-called convalescents who are daily deposited upon the wharf of the Board of Charities and Correction. The importance to these of the coffee-room, which is connected with their mission, can hardly be overestimated. There are dozens of drinking-shops waiting for the patient who has been discharged from Bellevue and Blackwell's Island, and it is well that there is at least one place where they may eat and drink that which will not in any manner provoke a new attack of the malady from which they have been suffering, or cause another accident which will render them subjects of the public bounty.

PROF. WILLIAM H. VAN BUREN, M.D., LL.D.

It will be a subject of congratulation to the many friends of Prof. William H. Van Buren to learn that he has been the recipient of the honorary degree of LL.D. from Yale College. This is the first time that such a degree has been conferred upon a medical gentleman by this institution, and it is peculiarly gratifying to the profession that Prof. Van Buren should be the one chosen for such a distinction. He has ranked for many years as one of the leading surgeons of the country, and his attainments as a medical scholar, as an author and teacher, are acknowledged to be of the highest order. With a full appreciation of the motives which actuated the trustees of Yale in conferring the degree, we scarcely know which is the more honored, the giver or the receiver. In view of the happy choice, it behooves us to congratulate both.

DEATH IN THE PROFESSION.

THE *Lancet* very feelingly and appropriately refers, in a recent issue, to the circumstances attending the death of Drs. Murchison and Tilbury Fox. Both were similarly afflicted with a mortal disease, and both were aware of the fact during the latter years of their lives. Yet, notwithstanding this, they worked faithfully in their profession to the last, and none but their most intimate friends knew of the dreadful clouds which were hanging over their inner lives. None but themselves knew of the terrible forebodings which were ever present to them in the hours of their greatest successes, and during the times when the hope for a prolonged period of usefulness would reach an agony of spirit never to be appreciated save by those who likewise suffer. Many in our ranks at present are carry-

ing about with them the dreadful consciousness of a mortal disease, are walking with calm desperation under the very shadow of death and are manfully striving to forget their doom in the excitement of work. The dreadful knowledge of an incurable disease is one which every physician strives to spare his patient. It is a burden so grievously borne by the ordinary run of mankind that some ray of hope is always left in the mind of the sufferer as he leaves the consulting-room. With the medical man who similarly suffers, the case is entirely different. As the *Lancet* truly and forcibly says: "But what blight can fall on the consciousness of the layman, what withering hope be felt within the mind that only partly realizes its own danger, compared with that which crushes the spirit and renders the heart faint in the breast of the well-instructed and experienced pathologist, who from the moment he hears from the lips of a trusted friend, or by his personal skill discovers the truth about his condition, foreknows his own doom." To avert it he knows is an impossibility, and yet with a fortitude which amounts to the sublimest heroism, calmly performs his duties to the last, forgetting his own suffering in the desire to alleviate that of his brother. We have in mind several of our friends who might be named in this category. One in particular is forced upon our recollection in this connection. It may not be known to all that the late Dr. Cammann carried with him for years the conviction of the existence of valvular disease of the heart. He made the diagnosis himself shortly after an accident which caused the lesion, and kept the secret from his family for many years, until shortly before his death; and yet during all the long period, with the constant reminder of his disease, which night and day murmured its existence to his cultivated ear, he made his reputation as the first auscultator of his day by heroically facing his enemy in the study of cardiac troubles. As we have already said, we might multiply examples, but it is sufficient to know that they are many, and that each and all serve to show that there is a compensation for the greatest of afflictions; that the severest trials develop the finest characters; and that even the omnipresent warnings of death can be lost in the calm determination to do the best we can while living, leaving the future in the hands of a kind Providence. The study of such examples is profitable for all, and the lessons which we may learn from them should be taken to heart.

COMBINATION OF CINCHONA ALKALOIDS WITH OPIUM.—Dr. D. P. Skillern claims: 1. This combination aborts the paroxysm of intermittent fever more certainly, and the cure of the disease follows more surely and rapidly than when the alkaloids are given uncombined. 2. Only half the dose of the alkaloids are required. 3. It relieves the associated painful sensations. 4. Exemption from headache, tinnitus aurium, etc. 5. It enables the stomach to retain the quinia. 6. Large and continuous doses of quinia may be given, without producing cinchonism, if combined with opium.

Reviews and Notices of Books.

DISEASES OF THE THROAT AND NASAL PASSAGES. A Guide to the Treatment of Affections of the Pharynx, Esophagus, Trachea, Larynx, and Nares. By J. SOLIS COHEN, M.D., Lecturer on Laryngoscopy and Diseases of the Throat and Chest in Jefferson Medical College, Philadelphia, etc., etc., etc. Second edition, revised and amended. With 208 illustrations. New York: William Wood & Co. 1879.

THE second edition of Dr. Cohen's work on Diseases of the Throat appears in the form of a well printed, bound, and illustrated volume, containing 750 pages. The changes made consist in the suppression of some of the old material, modifying and augmenting what has been retained, adding new material, discarding old and introducing new illustrations, and omitting entirely the bibliography. The space occupied by the latter has been filled with clinical material, and, now that there is no lack of indicators to sources of information in this branch of professional study, this change is a commendable one. Special manipulations, operations, and therapeutic measures have been described in the place in which allusion has first been made to them, and do not appear in separate chapters. This plan possesses certain advantages readily appreciated by the reader, and we think adds to the clinical interest of the book. The nomenclature from the most recently published edition of the U. S. P. has been employed. Into the present edition have been substantially incorporated the author's lectures delivered in 1872, 1873, and 1874, before the College of Physicians of Philadelphia, and the classes in Jefferson Medical College, and published in the *Philadelphia Medical Times*, the *Philadelphia Medical and Surgical Reporter*, and the *New York Medical Record*. Dr. Cohen is a clear writer, and has treated his subject in a manner which will be acceptable to the profession. The important changes and additions seen in the present edition render the first edition more ornamental than useful. The book in its present form will make a valuable text-book in this department.

POTT'S DISEASE: ITS PATHOLOGY AND MECHANICAL TREATMENT, WITH REMARKS ON ROTARY LATERAL CURVATURE. By NEWTON M. SHAFFER, M.D., Surgeon in charge of the New York Orthopædic Dispensary; Orthopædic Surgeon to St. Luke's Hospital, New York, pp. 82. New York: G. P. Putnam's Sons. 1879.

THE author of the volume before us does not state for what purpose it was prepared; he certainly did not design it for a practical work on Pott's disease, nor can it be called a pathological treatise. It is divided into two chapters: one on pathology, and one on the treatment of Pott's disease. There is nothing on its symptomatology, except what is interwoven with its pathology. Our author states that he prefers the name of "spondylitis" to any other—why, he does not state. It seems to us an error, both from its derivation—"spondylos," a vertebra, and "itis," inflammation—and its accepted use. Spondylitis is used to designate an entirely different disease, namely, an acute inflammation, *not* of the bodies of the vertebra, but of the *lateral masses*; rheumatic in its character, in which the outlying processes are locked together, as it were, by outgrowth from the periosteum, and is *not* accompanied by any *destruction of bone*. An acquaintance with the work of Julius Braun, published in Hannover in 1875, and a reference to the files of the

"*Journal of Nervous and Mental Diseases*," we think would have prevented the error that our author has made, as well as that of the distinguished professor from whom he differs so much.

By spondylitis, our author includes all diseases of the spinal column, usually denominated Pott's disease. He states on page 1, that "I have never seen nor obtained the history of an idiopathic, *acute* spondylitis;" while on page 23 it is stated, "acute inflammation of any of the appendages of the vertebral bones are quite rare, and I have only seen a few cases. Two of them, I am inclined to believe, were lesions of the intervertebral cartilages." Which statement does our author wish us to accept? On page 3 it is stated, "I have never had an opportunity to examine post-mortem the pathological condition of the vertebral column before the appearance of deformity," while a few lines lower down on the page, he states, "In the absence, among authors I have consulted, of other important facts bearing upon this point, and based upon *actual* and very *early pathological** exploration, I propose, with the aid I have derived from them, and from my own experience, both *pathological* and clinical, to consider the lesion from these standpoints." The exact meaning of the writer in these two contradictory statements we are unable to make out. He must have made a very superficial examination of "the very considerable number of works upon spinal deformity," which he informs us he possesses (page 32), not to have ascertained the fact that the disease may go on to a fatal termination without the development of *any* deformity, and that there are many reports of post-mortem examinations on record illustrating this fact. We would remark in passing, that a statement of what his "pathological experience" had been, would not have been out of place. On page 5, he says, in speaking of reflex spasm, "this reflex muscular spasm is due to an irritation, *peculiar* in its character, of the peripheral nerve, etc.,"* We should like to inquire what there is "*peculiar*" about it, and in what it differs from other nerve irritation, and how does he ascertain the fact?

He divides "Pott's disease, or chronic spondylitis," into four stages, namely: prodromal, one of pain, one of deformity, and one of abscess. He says, "I was tempted to make a fifth, namely, paraplegia, but this condition is so clearly symptomatic, and in reality occurs so rarely *under intelligent treatment*,* that I have classed it among the symptoms of any of the stages;" and in another portion of the volume states that paraplegia may occur without *any* deformity. We should like to inquire what the term "intelligent treatment" means, for we have seen cases in which paraplegia has come on, under what the author would recognize as "intelligent treatment." An acquaintance with the writings of Charcot, Michaud, and others, would have prevented his making a statement of this kind. The fact that paraplegia may come on before there is any deformity, proves that it is not dependent on the amount of disease, but rather on the location of the lesion in the bone or disc.

He divides the disease into a suppurating and non-suppurating variety (caries sicca), and states on page 9 in regard to the latter, "This extremely interesting condition I have seen *very** often clinically, both in the spine and large joints. . . . For reasons which I shall state hereafter, I think it very rare that this condition of caries sicca is seen in the vertebral column after death;" and on page 11, "that the general failure of vital force which precedes death, produces

* Italics ours.

an effect upon these fungous graulations which results in a rapid breaking down of the neoplastic proliferations.*

We would like to know how he proves that there is no pus about a diseased vertebra.

On page 414 of Billroth's Surgical Pathology will be found a similar statement, and almost in the same words as the latter portion of the above quotation.

On page 25 he states: "I was the first to call attention that a chronic disease may exist in any given articular tissue which is sparsely supplied with nerves, or which is devoid of neural elements, without presenting any subjective symptoms which are of sufficient importance to attract the attention of the patient."* How can you have pain in a tissue when there is no nerve? And on page 4 he makes the following quotation from Billroth: "*There are cases where the bone is extensively destroyed without any pain.*"* This was written by Billroth in 1869.

On page 28, he states "that reflex muscular spasm in chronic joint disease always indicates osteitis . . . Its presence is due to a direct pathological cause, a fact I was the first to point out." Birwell, in his work "On Diseases of Joints," page 244, says: "Pathology shows us that in synovial disease no especial action is produced among the muscles of the limb until the bone underlying the cartilage becomes affected . . . and such contraction is produced by a morbid form of reflex action carried from the nerves supplying the joint to the muscles." This was written in 1860.

On page 14 he makes some remarks on rotary lateral curvature, and claims he was the first to point out the fact that "chronic synovial inflammation is not accompanied to any great extent by muscular spasm." On page 18 he says: "I am prepared to state that rotary lateral curvatures has a specific pathological cause—not merely a mechanical etiology;" but he has strangely forgotten to state what the "specific pathological cause" is.

On page 13 he says: "Septicæmia and amyloid degeneration are the most frequent causes of death in the suppurative variety, while tubercular meningitis has only too frequently, in my own experience, followed upon the dry caries." It is a well-established fact in pathology that tubercular meningitis is usually secondary to suppurating foci in other portions of the body, and rather militates against the theory of the frequency of caries without suppuration. There are other points that we should like to refer to as inconsistent as those already mentioned, but space forbids. We cannot close this portion of our review without drawing attention to the fact that he has failed to give the history of a single post-mortem appearance in illustration of the condition "which he has seen very often clinically . . . and on several occasions after amputation and excisions of the larger joints."

The second chapter is on the treatment. He condemns the plaster-of-Paris jacket, on page 48, "as filthy, and failing to accomplish the object for which it is applied," yet, notwithstanding its filth, he advocates the use of a jacket, in a modified form, for the region included by the lumbar and five last dorsal vertebrae, and states: "I have found a modification of Taylor's antero-posterior support secured with a plaster zone." He describes the application of this support fully; but only states in a general way his mode of managing disease in other portions of the spine. In fact, there is nothing practical about this portion

of the volume, and one lays it down knowing but little more about the management of a case of "spondylitis" than before he took it up. The only novelties in the book are his "modified" plaster jacket, and the ball-and-socket-joint for Taylor's chin-piece, both of which are improvements. We notice an absence of any reference to the works of others in this field of surgery, except in a slurring style, and would suggest that "a mechanical demonstration" of the etiology of lateral curvature, illustrated in the dried and mounted vertebral column, and arranged with springs," etc., has the merit at least of originality about it, and is more satisfactory than the mere remark that "I am prepared to state, etc.," not supported by a single case bearing on the subject. Really, the best part of the volume is the quotations from Billroth, and these form no small part of it.

What the profession demand of our writing a book on any special subject is, that it shall be practical, and that the writer should state clearly the facts from which he draws his conclusions. Especially is this looked for from one who evidently prides himself on his pathological knowledge and his acquaintance with the literature of the subject on which he writes. We are sorry that we find so much to find fault with, and so little to praise, in a book written by one who has had an experience of "fifteen years" in the treatment of spinal deformities.

POSOLOGICAL TABLE: Including all the Official and most frequently employed Unofficial Preparations. By CHAS. RICE, Chemist Department of Public Charities and Correction, New York. Revised and approved by members of the Medical Boards of Bellevue and Charity Hospitals. New York: William Wood & Co., 27 Great Jones Street. 1879.

This compend, constructed for the use of physicians and apothecaries, gives the names of medicines, the definitions of crude drugs according to the present state of our knowledge, and the average adult doses used in regular practice. From an appended table the proper average doses for children can be easily ascertained. The doses are given in the usual apothecaries' system, but rules and tables have been appended by which change into the decimal quantities of the metric system is readily accomplished. The medicines are arranged in alphabetical order. The author designed to make this book a convenient guide, and we believe he has been eminently successful.

GENERAL SURGICAL PATHOLOGY AND THERAPEUTICS IN FIFTY-ONE LECTURES. A text-book for students and physicians. By DR. THEODOR BILLROTH, Prof. of Surgery in Vienna. Translated from fourth German, and revised from eighth edition, by CHARLES E. HACKLEY, A.M., M.D., Physician to N. Y. Hospital. New York: D. Appleton & Co. 1879.

The subjects discussed in this book have such a practical bearing, not only by themselves, but in relation to each other, that no one is surprised that success has attended the labors of the author, and that his work has reached the eighth edition. The plan of the work is such as enables the author, in the midst of the discussion of a pathological question, to apply a principle of treatment, of prognosis, and of diagnosis. This arrangement invests the study of its contents with great interest, and helps in a very direct and practical way, in studying the fundamental principles of pathology. In this respect it may be said to supplement the various works on general surgery, by giving the every-day experience of a thorough and practical teacher at the bedside and in the post-mortem room. As the interest in true pathology increases, so

* Italics ours.

will the popularity of this work. The English translation is that of the sixth German edition, but is made to correspond with the eighth German by the addition of an appendix, which contains the extra matter.

Reports of Societies.

THE AMERICAN NEUROLOGICAL ASSOCIATION.

Fifth Annual Meeting, held in the City of New York, June 18, 19, and 20, 1879.

(Continued from p. 17.)

THURSDAY, JUNE 19TH.—SECOND DAY—AFTERNOON SESSION.

The Association was called, to order at 2.30 P.M. by the President.

The minutes of the previous day² were read and approved.

REPORT FROM THE COUNCIL.

The Council reported that it had examined the papers presented by the two candidates for membership, and recommended that they be elected members by the Association.

On motion, the By-Laws were suspended, and the Secretary was then instructed, by motion, to cast an affirmative ballot for Drs. W. J. Morton and R. W. Amidon, of New York.

AMENDMENT TO THE BY-LAWS.

The amendment to the By-Laws offered by Dr. Grey was adopted by the Association.

Dr. HAMMOND offered an additional amendment as follows: "The presentation of a written neurological communication shall be deemed a valid excuse for absence from an annual meeting of the Association."

COMMITTEE ON NOMINATIONS.

The President announced the following Committee on Nominations: Dr. H. D. Schmidt, of New Orleans; Dr. E. C. Spitzka, of New York; Dr. A. D. Rockwell, of New York; Dr. J. J. Putnam, of Boston; and Dr. J. C. Shaw, of Brooklyn.

PRESENTATION OF CASES.‡

DR. A. D. ROCKWELL, of New York, presented cases illustrating two important points in electrotherapeutics: 1. The necessity for and the good results which come from perseverance in the use of electricity in seemingly hopeless cases of infantile paralysis. 2. Differentiation in the use of galvanism and faradism for the relief of pain.

In the neuralgic case the faradic current was used after various forms of treatment had been adopted without benefit, and after four applications recovery was nearly complete, the disease having existed six months. It was a case of neuralgia in which firm pressure did not produce pain, while slight pressure produced great pain. In differentiating whether galvanism or faradism should be used for the relief of pain, the effects produced by pressure were most useful guides. While, however, true neuralgia and pain generally yielded more readily to the galvanic than to the faradic current, the latter was in some cases invaluable, and yielded good results when galvanism was useless. As a general rule, firm pressure well borne indicated the use of faradism.

With reference to the case of infantile paralysis, DR. MILES asked if voluntary movements had returned to the muscles.

DR. ROCKWELL replied that they had; that they were marked, and that they had returned after an absence of six months, after all normal recovery had taken place.

DR. MILES remarked that he had succeeded in such cases in restoring galvano-muscular contractility, but not voluntary action.

WHICH POLE SHALL BE EMPLOYED?

DR. L. C. GREY, of Brooklyn, asked which pole was used for the relief of pain.

DR. ROCKWELL replied that he used the descending current.

DR. HAMMOND remarked that he had reached the conclusion that it did not make any difference with regard to which pole was employed, and that the one was as good as the other.

DR. ROCKWELL remarked that to reach correct conclusions upon this, as upon other interesting points, considerable observation was necessary. He had seen cases in which, after obtaining very good results from the use of the descending current, he had, in order to hasten the improvement, used the ascending current, and all the pain returned.

DR. HAMMOND remarked that he had seen such a result from the continuous use of one current, either the ascending or the descending.

DR. GREY remarked that his experience had led him to the conclusion that it made but little difference which pole was employed, except about the eye or face. Upon the face he had found a difference in the effect produced by using different poles, and he had explained the difference by the fact that in physiological experiments and therapeutical uses of electricity the conditions were essentially different; in the one the nerve was laid bare, while in the other it was more or less deeply covered with tissues. When deeply covered, the electricity became so diffused that its direct action upon the nerve was questionable, while in regions in which the nerves were less deeply covered the conditions present in physiological experiments were more closely approximated. He then referred to a case in which so long as he used the descending current there was an amelioration of symptoms.

DR. BEARD remarked that the most interesting feature of Dr. Rockwell's case was the fact that the faradic current gave relief to the pain. It had been stated for such forms of disease we must use the galvanic current exclusively. In the cases of sciatica reported by Dr. Gibney, of New York, that idea was involved, and it was a popular opinion in Europe at the present time; but it was erroneous.

The suggestion made by Dr. Rockwell with reference to pressure as an indicator in differentiation as to the use of galvanism or faradism to relieve pain, was perhaps a good general guide; but it was not applicable to all cases.

With reference to the direction of the current, theoretically, there should be a difference, but, practically, he was not able to make the differentiation.

DR. E. C. SEGUIN thought we could be guided by the polar test, according to the instruction given by Erb, with reference to the current to be employed. With regard to relief of pain, his experience had been favorable to the sedative effects of the anode, provided a mild current was used, and to the exciting effect of the cathode.

DR. BEARD remarked that, in a majority of cases,

pain was relieved when a sufficiently mild current was used.

For the first four or five years of his practice he always knew what pole he employed, but of late years, in very many cases, he did not know, and he was not able to recognize any change in the results of his electrical treatment.

Dr. W. J. MORRIS, of New York, remarked he felt quite sure that, in neuralgia of the trigeminus the positive pole reduced pain in cases in which the negative pole produced no marked effect.

The polar difference could be distinctly seen when the poles were kept sufficiently long in contact with the tissues. Dr. Morton then referred to the fact that ulcers healed rapidly when the positive pole was applied to their surfaces, while they became deeper under the influence of the negative pole, and besides several small superficial ulcers might be produced by the negative plate.

Dr. GREY thought there could be no question but that there was a physiological difference between the poles, but he failed to see that there was convincing evidence to prove any therapeutical difference.

Dr. HAMMOND thought Dr. Grey would change his opinion when he witnessed the result of electrical treatment of ulcers.

Dr. GREY remarked that he had used electricity in the treatment of abscess, and that he had not seen any difference in the results obtained by the use of different poles.

Dr. HAMMOND remarked that he knew there was a therapeutical difference between the positive and the negative poles, and that fact he first established to his own satisfaction in a series of cases of ulcers treated by galvanism at the Baltimore Infirmary several years ago. He knew that a silver (*positive*) plate placed upon an indolent ulcer, with a zinc plate (*negative*) above, facilitated healing; whereas, applied in the opposite manner, the condition was invariably aggravated. The single pair of plates gave the least possible intensity.

Dr. GREY remarked that he did not question the difference in the results in the treatment of ulcers; but he should not, from that fact, argue with regard to the therapeutical value upon the unbroken skin.

Dr. BEARD thought there was no chance for dispute with regard to the effects produced upon ulcers by different poles, the positive being the more efficacious for healing purposes. He believed there was one thing sure—namely, that in all countries where electricity was used, there was less and less tendency to insist upon polar use. The best writers took the view that the practical difference between the positive and negative pole was not so much as formerly supposed.

Dr. GREY remarked that he did not believe there was any difference with regard to the direction of the current; and that, if there was a difference it was between the poles.

Dr. MILES remarked that he had seen unmistakable difference between the two poles in allaying pain. In the treatment of myalgia occurring in his own person, he had found that the positive pole gave him relief much sooner than the negative.

INFANTILE ENCEPHALITIS FOLLOWED BY ATHETOTIC SYMPTOMS.

Dr. E. C. SPITZKA exhibited a patient who had athetotic symptoms, as he believed, the result of infantile encephalitis.

GLOSSO-LABIO-LARYNGEAL PARALYSIS.

Dr. HAMMOND presented a patient suffering from

the above disease. The treatment was, phosphide of zinc, one-tenth of a grain, t. i. d., and extract of nuxvomica, one-third of a grain, t. i. d. Electricity was also used; and, while the patient was certain that he was improving, Dr. Hammond thought his condition would never be substantially improved.

MYELITIS WITH THE FORMATION OF CAVITIES OR VACUOLES IN THE GANGLION CELLS IN THE ANTERIOR HORNS OF THE SPINAL CORD.

Dr. R. T. EDES, of Boston, read a paper in which was given the clinical history of a case that developed, orderly and symmetrically, symptoms referable to the spinal cord. There was symmetrical atrophy of the legs below the knees, and the arms below the elbows, and the left pupil was larger than the right. The case was of a little less than four months' duration, and on microscopical examination of the cord the white substance was found normal in every respect. In the gray matter the only change consisted in the presence of large polygonal spaces or vacuoles in varying numbers in the anterior horns. The processes of the ganglion cells seemed slightly changed in places—shrunk and shortened. The lesion was found in the cervical enlargement, in the dorsal region, and in the lumbar enlargement. The specimens seemed to illustrate that parenchymatous changes might take place independent of blood-vessels or neuroglia.

Dr. PUTNAM remarked that he had seen a case closely resembling Dr. Edes's in clinical history, except that the fever was higher, the temperature rising as high as 104°-105° F. There was the same progressive paralysis, and, on microscopical examination, spots of softening were found in the lenticular ganglion upon the left side. In the cervical region there was an evident change in the ganglion cells consisting in large collections of fat. He thought that it was possible, if the case had lasted longer, the change might have gone on to the formation of vacuoles.

Dr. E. C. SEGUN referred to specimens in his possession, of acute myelitis, in which the symptoms of transverse and total myelitis were developed within twenty-four hours. Death occurred at the end of the sixth or seventh week, and on examination he found extensive softening of the lower dorsal cord, which microscopically exhibited no special lesion, but in sections below, the first of moderate worth, there were found vacuoles, such as described by Dr. Edes.

He thought the clinical history of Dr. Edes' case belonged to polio-myelitis more nearly than anything else.

Dr. SCHMIDT, of New Orleans, thought the so-called vacuoles in the specimens were globules of fat. In some of the ganglion cells granular degeneration was present, which commonly preceded the formation of free fat-globules.

The Secretary read a communication from Dr. J. S. Jewell, of Chicago, expressing his regret at not being able to be present, because of serious sickness in his family.

Dr. J. J. MASON exhibited micro-photographs illustrating

THE HISTOLOGY OF THE MEDULLA OF THE ALLIGATOR, after which the Society adjourned, to meet at 8.30 P. M.

SECOND DAY—EVENING SESSION.

The Association was called to order by the President.

The proceedings began with remarks by Dr. Wm. A. HAMMOND, of New York, on

METALLO-THERAPY.

He referred to its history, spoke of his own work in connection with the subject, and expressed his great surprise that a man of such scientific training and experience as Charcot should have lent himself to so vile a humbug. Dr. Hammond showed disks of various metals which he had used in his experiments, and asserted that the one of tortoise-shell was the most efficacious, and was the one used most.

The subsequent discussion of the matter showed it to be the unanimous feeling of the Society that the claims of metallo-therapy were unfounded and absurd.

In view, however, of the fact that it was not yet universally condemned by physicians, and even had the support of some eminent men, it was voted that a committee be appointed to investigate the matter, both in its medical and psychological phases.

Dr. W. J. MORTON, of New York, then read a paper upon the

TOXIC EFFECTS OF TEA.

The subject, he said, was best studied by examining that class of men, such as tea-tasters, who habitually took tea in large amounts. It was, however, not easy to obtain extensive data concerning those men, for they feared if the facts become known it might injure their business. Five cases, however, had been collected, and those, together with experiments performed by the writer upon himself, formed the basis of the paper.

The bad effects of tea-tasting were known and recognized by the tea-tasters themselves, and few could carry on the business many years without breaking down. One tea-taster estimated that he got about half a pound of tea into his system during a day. It has been said that the symptoms from which tea-tasters suffered were due to alcohol or dyspepsia, but the facts collected showed the contrary.

The writer then gave the history of the cases referred to, and of the experiments upon himself.

The following is a resumé: First, as to the immediate effects of moderate doses, there was in the cases observed, an elevation of pulse, increase of respiration, agreeable exhilaration of mind and body, a feeling of contentment and placidity, an increase of intellectual and physical vigor, with no noticeable reaction.

The immediate effects of an excessive dose were rapid elevation of pulse, marked increase of respiration to the extent of about one-third, increase of temperature, no period of exhilaration, but immediate and severe headache, dimness of vision, ringing in the ears, dulness and confusion of ideas. Following that was a severe reaction; exhaustion of mind and body, tremulousness and "nervousness," and dread of impending harm, that could not be relieved by taking more tea.

The effects of continued doses were a continuance of the tremulousness, extreme susceptibility to outside impressions, constipation, diminution of urine, and marked influence on the metamorphosis of tissue as shown by the diminution in the amount of urea. Thus, in the week during which the writer was taking toxic doses of tea the amount of urine fell from $f\frac{3}{4}$ xl. to $f\frac{3}{4}$ xxxii. per day; and in the same time the urea fell from gr. 591 to gr. 422 per day. The sulphates, phosphates, and chlorides were increased.

The results as regarded the diminution of urea agreed with previous experiments, but showed the influence of the tea much more strikingly.

From the study of the drug's action, Dr. Morton arrived at the following conclusions:

1. That with it, as with any other potent drug, there was a proper and an improper use of it.

2. That in moderation it was a mild and pleasant stimulant, followed by no harmful reaction.

3. Its continued and immoderate use led to a very serious group of symptoms, such as headache, vertigo, ringing in the ears, tremulousness, "nervousness," exhaustion of mind and body, with disinclination to mental and physical exertion, increased and irregular action of the heart, and dyspepsia.

4. The mental symptoms were not to be attributed to dyspepsia.

5. It diminished the amount of urine, and retarded the metamorphosis of tissue.

6. Many of the symptoms of immoderate tea-drinking were such as might occur without a suspicion of the real cause.

The paper being open for discussion, Dr. J. J. PUTNAM, of Boston, asked whether the symptoms of weakness, nervousness, etc., which followed the taking of large doses were those of reaction, or were the continued toxic effects of the drug.

Dr. MORTON thought that they were the latter.

Dr. HAMMOND referred to a case of his where the patient suffered intensely from neuralgia brought on, he believed, by tea-drinking.

Dr. MILES asked if the tea-tasters were subject to any great mental strain or anxiety in their business.

Dr. MORTON said that they were not. Referring to the influence of alcohol, he asserted positively his belief that it had nothing to do with the train of symptoms he had given. There was, to be sure, very often a craving for alcohol, but it was not uniformly felt, and the danger of drinking was appreciated by the tea-tasters.

The Association then adjourned to meet on Friday at 2.30 P.M.

FRIDAY, JUNE 20TH.—THIRD DAY—AFTERNOON SESSION.

The Society was called to order at 2.30 P.M. by the President.

The minutes of the previous day were read and approved.

The amendment to the By-Laws proposed by Dr. Hammond was adopted.

REPORT OF COMMITTEE ON NOMINATIONS.

The Committee on Nominations made the following report:

For President—F. T. Miles, M.D., of Baltimore, Md.

For Vice-President—R. T. Edes, M.D., of Boston, Mass.

For Secretary and Treasurer—E. C. Seguin, M.D., of New York.

For Council—Dr. F. K. Kinnient, of New York, and Dr. L. C. Grey, of Brooklyn, N. Y.

Dr. GEO. M. BEARD presented two patients who illustrated anthropophobia and topophobia. Both were strong, vigorous men.

THE DOSAGE OF ELECTRICITY.

Dr. GEO. M. BEARD read a paper on the above subject, in which he stated that the dosage of electricity was a complex result of a number of different factors.

1. The strength of the current.

2. The length of the application.

3. The quality of the application, and

4. The method of the application.

1. The strength of the current.—It was difficult to

estimate that, and to say that we had treated a patient with so many cells was saying but little. The size of the electrodes, the manner of their application, and the moisture of the skin, must all be taken into consideration. The resistance offered by the skin was also an important element, for it was variable, and besides, the quality and temperature of the water were important considerations in making an estimate.

The amount of electricity passing through the body was varied by—

- a. The electro-motive force of the battery.
 - b. The internal resistance within the battery; and
 - c. The external resistance outside of the battery.
2. The length of the application could not be determined with minute precision. As a rule, European neurologists made shorter applications than did the American. There was no question but that long applications exhausted muscles, and an application of one or two minutes' duration to a paralyzed muscle was all that was beneficial. The beginning of electrical treatment should be with short applications and mild currents.

No absolute rules could be given regarding strength of current or length of application. Other things being equal, a stronger current required shorter applications. Other things being the same, the galvanic current was not so well borne for a long time as the faradic current of corresponding strength.

3. The quality of the application. The use of mild currents at first was wise. Experience compelled us to admit that stimulating as well as sedative effects could be obtained by negative as well as positive poles. Practically, the difference between the positive and the negative poles, and between the ascending and the descending currents, was one of degree rather than kind.

4. The method of application was largely included in what had been said. He had long ago recommended the terms, medium, mild, and strong currents, as the best approximation possible to a fair description of the doses of electricity.

Again, the dosage of electricity was modified by the external position of the poles. The same strength of current with the negative pole was a stronger application of electricity than with the positive pole in the same locality.

Even the best constructed galvanometers interposed in the circuit could not be an accurate measure of the dosage of electricity, for the reason that the amount of electricity passing through the body of the patient would vary with the pressure on the sponge and with the position of the electrodes. Consequently there might, in different applications, be the same number of degrees indicated by the galvanometer, while the applications really were very different in their character and in their effects, because the electrodes were differently placed.

Temperament was another element to be taken into consideration in regulating the dosage of electricity.

Finally, what was true of familiar drugs, and the conditions regulating their dose, was true of electricity.

DR. ROCKWELL remarked that, in his opinion, the only rule that could be laid down with reference to the dose of electricity was that the faradic current should never be given of such strength as to make it unpleasant for the patient, except in treating paralysis; and the same held good with reference to the galvanic current. He had experienced advantage from the use of a long-coiled galvanometer, although the instrument had no practical value except to show

the presence of a current and to determine the positive and the negative poles. He also spoke of the benefits of general faradization.

DR. GREY spoke of the good effects of general faradization, and then followed a long discussion regarding the manner of its application, which was participated in by Drs. Rockwell, Grey, Hammond, and Beard, and finally the discussion was postponed until the evening session.

PATHOLOGICAL LESIONS IN THE NERVOUS SYSTEM IN YELLOW FEVER.

DR. H. D. SCHMIDT, of New Orleans, demonstrated microscopical specimens prepared from the brain and spinal cord of patients dying of yellow fever.

From his experience in that disease he was satisfied that, in the great majority of cases, death occurred from congestion of the brain. If the case had sufficient duration, pathological changes occurred in the ganglionic bodies of the nervous system. Fatty degeneration and fatty infiltration were prominent characteristics of this disease, and the fatty change was developed within four or five days in some of the organs. His observation had not been sufficiently extensive to enable him to say whether the fatty changes were due to direct effects first upon the blood or first upon the nervous system, or whether there was a double action. He had made sixty autopsies in yellow fever cases, and in all instances in which he had made microscopical examinations he had found the brain congested, sometimes throughout, sometimes in certain portions, especially in the parietal lobe. In some cases he found the ventricles filled with serous fluid and sometimes purulent. During the last epidemic he examined the spinal marrow and the sympathetic system, especially the semilunar and the first thoracic sympathetic ganglia. To his surprise he found in the semilunar ganglion, also in the thoracic, that the nuclei of the ganglion cells were entirely gone, and besides, that the ganglion cells had a true fatty lustre. The ganglionic cells in the cortex cerebri had undergone fatty degeneration, and in almost all cases it was difficult to recognize the ganglionic cells. The object of exhibiting the specimen was simply to show that the congestion in yellow fever was throughout the entire brain in the great majority of cases; cerebrum, cerebellum, pons, and medulla oblongata.

With regard to convulsions which had been described as uræmic, he did not believe they were of that character. He believed that suppression of urine occurred only in exceptional cases of yellow fever. In 1867, in the course of a large practice in yellow fever, he saw but two cases of real suppression of urine; almost uniformly such cases were cases of retention, and he had usually found urine in the bladder of persons dying with what had been supposed to be due to suppression of urine.

Dr. Schmidt did not accept the doctrine advanced by Dr. Richardson of Philadelphia, that the tubules of the kidneys were filled with bacteria; they were blocked up with disintegrated epithelium, and he did not accept the opinion that the blood underwent decomposition.

CHOREA IN HYSTERICAL CHILDREN.

DR. G. C. GREY, of Brooklyn, read a paper containing the histories of several cases in which chorea and hysteria coexisted in the same children; three girls and one boy. The paper was discussed by Drs. Spitzka, Rockwell, and Hammond.

DR. R. W. AMIDON, of New York, then read

A CONTRIBUTION TO THE STUDY OF CEREBRAL LOCALIZATION.

The paper consisted in a study of six cases of lesion of the brain: 1. Traumatic capillary cerebral apoplexy; 2. Cyst of the pia mater; 3. Cerebral laceration and hemorrhage—traumatic; 4. Old yellow patches of softening; 5. Pistol-shot wound of the head; and 6. Pistol-shot wound of the head, with a remarkable magnitude of injury without cerebral symptoms. In the last case there was perfect exemption from paralysis and no aphasia.

In the opinion of the author of the paper, localization of destructive or irritative lesion in the motor district of the brain had reached as near perfection as it ever would, for small patches of gray matter occupied only similar positions in all processes, and might be found in a slightly different level in different brains.

On motion, the discussion was postponed until the evening session.

The Society then adjourned, to meet at 8.30 P. M.

THIRD DAY—EVENING SESSION.

The Society was called to order by the President.

The discussion upon Dr. Amidon's paper on the "Localization of Cerebral Functions" was continued.

Dr. E. C. SPITZKA, of New York, remarked that the tendency had been for some time to localize lesions too closely, and he was pleased to notice that Dr. Amidon had appreciated the error of this method, and had recognized the anatomical variability of the brain.

Dr. AMIDON remarked that in fetal life the brain was first a mere vesicle, with perfectly smooth external surface, with nerves running to it. It was probable that in this smooth surface motor centres were already established. When the fissures began to appear and the sulci to form by foldings in of this outer membrane, the centres might be carried by such foldings sometimes in one direction and sometimes in another. In this way the motor centres, for instance, might be brought either in front or behind, or even at the bottom of the fissure of Rolando. A motor centre, therefore, could not be invariably referred to a particular convolution, but must be indicated by a pretty large area of tissue.

Dr. SEGUIN remarked that for some time he had recognized this fact, and had been in the habit of indicating the various centres by rather large areas, which occasionally overlapped each other.

CEREBRAL HEMORRHAGE.

The PRESIDENT (Dr. MILES) then showed the brain of a person whose history was as follows: He had been suffering from Bright's disease, and was suddenly taken with right hemiplegia of arm and leg. When first seen by the speaker, immediately after the attack, his mind and speech were perfectly normal. He soon began to recover the use of his arm; and later, in three or four weeks, movement began to return to the leg. Before recovery was complete, however, the patient died. Post-mortem examination showed the existence of a small circumscribed clot, partially absorbed, in the left hemisphere at a point where a section passing through the anterior frontal convolution downward, not quite parallel with the fissure of Rolando, would cut into it. It was a region supposed to be motor. The case was particularly interesting, however, because the clot was very circumscribed; it did not involve the cortex, but only the nerves running to the cortical motor centres, and there was no mental disturbance with it.

Dr. E. C. SEGUIN, of New York, related two cases, showing

ABNORMAL SEXUAL EMOTIONS.

interesting chiefly in their psychological bearings. A female patient, perfectly well except for attacks of migraine, experienced occasionally the sexual orgasm while sleeping and dreaming; the dreams that excited the orgasm not being at all of an erotic character. On the contrary, the orgasm was generally excited by some emotion of great disappointment. At the climax of such disappointment the orgasm would be experienced. The other patient suffered in a similar way. The cases showed an apparent violation of the law of association of ideas, and a certain variation from the ordinary way in which the orgasm was brought about.

Dr. SEGUIN also exhibited sections of a spinal cord in a case of myelitis, these sections showing the

VACUOLES, OR DROPSY CELLS,

which had been referred to in previous discussions. The sections were made from just below the seat of greatest inflammation.

Dr. SPITZKA related the case of a patient who had died from a

CYSTIC TUMOR AT THE BASE OF THE BRAIN.

The tumor was oval in shape and about the size of a small orange. Its exact nature could not be determined, but it probably originated from the dura mater. During its growth the patient gradually became blind, paralytic, and insane. Four distinguished neurologists had during life pronounced upon it four different diagnoses, not one of which was correct.

Dr. SPITZKA read also the abstract of a more elaborate article upon

THE PEDUNCULAR TRACTS OF THE ANTHROPOID APES.

The object of the paper was to show the homologies that existed between these structures in man and the animals just below him. That field had not previously been worked up, and yet its study revealed greater evidence of structural affinities than the study of the hemispheres. The conclusions reached were that the differences in those tracts between man and the anthropoids was less than that which often existed between the tracts in different men, and that there was in fact a structural identity between the man and the ape next below him.

The discussion of the paper was postponed till the next meeting of the Association.

Dr. J. C. SHAW, of Brooklyn, read a paper upon

TENDON-REFLEX IN THE INSANE.

He had examined 130 insane paretics in reference to this symptom. Ten of those had general paralysis, of whom tendon-reflex in 3 was absent. All the cases had a certain ataxia of gait. In the early stages of the general paralysis he had never found the reflex abolished. In 15 other cases of dementia, etc., reflex was absent. Two or three of those were cases of senile insanity. In 29 of the remaining cases reflex was slight; in 76 it was normal.

The conclusion arrived at was, that if tendon reflex was present in paretics, degeneration of the posterior columns might be excluded.

All were agreed that the tendon-reflex was a reflex phenomenon, and we should expect a lesion in the lower part of the cord to account for its absence. Dr. Shaw presented sections of the cord of a patient in whom tendon-reflex was absent, showing such a lesion. Other specimens were shown illustrating the idea that in chronic meningo-myelitis the changes were apt to

be more marked and more frequently seated in the posterior portion of the cord, in this way abolishing tendon-reflex.

DR. SPITZKA stated that he had at one time made an examination of 40 cases; and his examinations, so far as they went, tended, like those of Dr. Shaw, to show that the abolition of tendon-reflex was an indication of a lesion in the posterior columns of the cord.

The Association then adjourned, to meet on the third Wednesday in June, 1880, in the city of New York.

Correspondence.

ANTISEPTIC TREATMENT OF WOUNDS —CARBOLIC ACID VERSUS ALCOHOL.

TO THE EDITOR OF THE MEDICAL RECORD.

MY DEAR SIR:—It is not my intention to enter into a discussion of the scientific question raised by Dr. Perrin in the *Union Médicale*, or even the comparative merits of these methods of wound treatment. Prof. Lister's system is probably so well known to the readers of your valuable journal that it does not require a description here; but as the treatment of wounds with alcohol has never been much employed beyond the borders of France, I will venture to give a brief description of its use and a page of its history.

The usual treatment of wounds with alcohol begins immediately after the ligation of the bleeding vessels, by washing the raw surface with strong commercial alcohol—although some surgeons prefer to dilute it slightly with water—after which it is carefully dried with some soft linen. When a cavity remains after an operation it should be filled up; and, in case of an amputation, after the approximation of the flaps, the stump should be covered with charpie which has been saturated with alcohol. The stump or wounded part is now covered with an impermeable layer of oiled silk or gutta-percha tissue, which is retained in position by a few turns of a roller bandage. This dressing should be changed sufficiently often to preserve the required degree of alcoholic moisture, or, in some cases where the charpie is not too much soiled, it may be sufficient to remove the oiled silk and re-apply the alcohol.

The alcohol treatment is continued so long as there is reason to fear septic infection, and then usually gives place to some other method which is supposed to hasten more rapidly the cure.

This method of wound treatment, like most others, is variously modified to suit particular cases or the fancy of different surgeons.

The following historical sketch from "*Histoire de la Chirurgie Française, par le Docteur Jules Rochard*," may possibly interest those who read your editorial of June 14, 1879, on this subject. Dr. Rochard says: "The interest inspired by the question of disinfectants had not yet died out when the attention of surgeons was called to another method, which recommended itself by its simplicity and its ancient origin. It was no longer a question of the effect of a new product of chemistry, but it was one of the most common agents, and one very generally used in therapeutics. Alcohol has been employed in the treatment of wounds by surgeons of all ages. A. Paré, Dionis, Percy, and Larrey were acquainted with its medicinal virtues, and the laity have never

lost sight of them. All the balsams and the vulneraries owe their principal curative properties to alcohol—from the balsam of the centenary plant to the tincture of arnica, which the laity still consider a panacea, and the tincture of camphor, which the works of Raspail have restored to fashion in certain classes of society. It was therefore without surprise that the Academy of Sciences received, in 1859, a memoir in which Batailhe and Guillet reported their experience in the employment of alcohol and alcoholic compounds in surgery.

Lestocquey, of Arras, in 1848, and Prof. Dolbeau, in 1859, had used it before them, but without attaching to it any great importance, and the memoir of Batailhe and Guillet had itself passed almost unperceived, when, in 1863, Nélaton adopted this mode of treatment at the "Hôpital des Cliniques." The results were very satisfactory. The wounds were maintained in a state of strict cleanliness, and preserved their ruby aspect under the cover of a light film of plastic lymph, and cicatrization appeared to progress more rapidly than by any other method. Secondary accidents were almost always averted, and among ninety-seven patients thus treated they reported only two cases of purulent infection and five of erysipelas.

These facts were brought before the public by two internes of their service: Chedeveigne, now professor in the medical school of Poitiers, and De Gaulejac. Chedeveigne had discovered, however, that the alcohol decomposes pus, removes its odor, and converts it into a greasy albuminous substance. He had seen with the microscope the purulent globules instantly dissolve on contact with the alcohol. Following this publication, the use of alcohol had spread still more rapidly than that of the disinfecting powders. Every one hastened to experiment with a remedy which was always at hand.

Marc Sée, in a memoir read to the Society of Surgery, December 12, 1856, confirmed the facts observed at the "Hôpital des Cliniques," and presented alcohol as a prophylactic in purulent infection. This last conclusion appeared a little hazardous to some of the members of the Society, and especially to Velpeau and Hippolyte Larrey. The fact is, that even at the "Hôpital des Cliniques," and under the eyes of Nélaton, cases of purulent infection had occurred during the course of this treatment, and this was fully demonstrated elsewhere.

We will farther on express more fully our opinion as to the prophylactic value of all these modes of treatment. For the present we will limit ourselves to stating that alcohol, being always within reach, may have its advantages, and that the surgeons who have restored its use have rendered a true service.

Yours very truly,

B. A. WATSON.

JERSEY CITY, N. J., June 23, 1879.

POISONING BY RHUS RADICANS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The treatment of this annoying affection of the skin was purely empirical until the discovery by Prof. Maisch, of Philadelphia, that the toxic agent in rhus-poisoning was an acid which he called *toxicolendric acid*. Since this discovery of Prof. Maisch's the treatment of this troublesome disease has been more rational. I have used the alkaline bicarbonates and lime-water both locally and internally in this affec-

tion with fair success, but this season have been using a saturated solution of hyposulphite of soda, keeping the affected skin moist with the solution, and in severe cases have given the hyposulphite internally at the same time. By this treatment I have aborted the worst cases in from 24 to 48 hours. I am sure any one giving the hyposulphite a trial in rhus-poisoning will reach the same conclusion that I have—that it is the best among all known remedies for curing this disease, and it fulfils the indications of a good medicine

Respectfully yours,
WM. E. BRANDT, M.D.

HANOVER, INDIANA.

HEAT AND COLD TO THE SPINE IN UTERINE INERTIA.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Monday evening, May 9th, I was called in a case of labor. The woman was stout and robust, æt. 26, and gave the following history: She had previously been twice confined; her first labor had been marked by uterine inertia, and extended, she stated, over a period of thirty-six hours; her second confinement had been of like character, but had been terminated by instrumental aid. I ascertained that slight contractions had occurred about an hour previous to my arrival. By examination I discovered a condition of ante-flexion of the uterus; the abdominal wall projecting downwards and forwards. This condition, I was informed, had existed in her previous accouchements. The depressed fundus I raised and supported with a bandage, which, in conjunction with the supine position, seemed to bring the axis of the uterus more into coincidence with the brim. The contractions now became somewhat vigorous and regular, and so continued until the presenting part, the head, became firmly engaged, when complete uterine inertia supervened. The patient now stated that the "same thing" had happened at this time in her former labors.

Frictions over the uterus were now employed, but I could obtain no effect therefrom; a dose of fl. ex. ergot, Squibb's, was immediately rejected by the stomach, while ergotin administered hypodermically elicited no response from the uterus. The forceps now appeared to be the only resource, but I feared that in a case like this of absolute inertia, forceps delivery would be followed by alarming, or even fatal, hemorrhage. I determined to try one other method of awakening the inert organ—that of cold to the spine and accordingly placed an ice-bag to the lower part of the spine, and awaited developments. The effect was magical. In less than two minutes by the watch a contraction occurred, followed by another and another, and of excellent quality, too; this state of affairs lasted five or ten minutes, when the contractions began to decrease in intensity and frequency, whereupon the ice-bag was removed and a flannel compress wrung out in very hot water substituted for it. Again was the uterus awakened and forced to do its duty, and as soon as it began to flag the cold was applied, etc. Thus, by the alternate use of heat and cold to the spine, the uterus was brought under complete control, and the labor quickly and happily terminated in the birth of a female child weighing nearly twelve pounds.

Respectfully,
A. C. HOFFMAN, M.D.

76 ERIE STREET, JERSEY CITY, N. J.

Obituary.

WILLIAM K. BROWN, M.D.

DR. WILLIAM K. BROWN died of apoplexy at Narraganset Pier, on Friday evening, July 4, 1879. He was born in Boston, July 8, 1806. He graduated from Dartmouth College in 1829. He subsequently practised medicine in Portland, Me., and in Philadelphia, after which he went to France, where he pursued his studies for two years under the famous French surgeon, Velpeau. He returned to this country and located in Brooklyn in 1841, where he became a successful practitioner. He was one of the oldest resident physicians of that city, was a prominent member of the Kings County Medical Society, and a Fellow of the New York Academy of Medicine. He visited Narraganset Pier hoping that the change would benefit his health, which had been declining since he received an injury some four years ago. He was quite well on the morning of the fourth, and fell a victim of death at 9.30 in the evening, at the ripe age of 73 years.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 29 to July 3, 1879.

WHITE, C. B., Major and Surgeon. When relieved to proceed to New York City and report arrival, by letter, to the Surgeon-General. S. O. 150, C. S., A. G. O.

STERNBERG, GEO. M., Major and Surgeon. Relieved from temporary duty at Washington, D. C., and to report in person to the President of the National Board of Health for duty with the "Havana Commission." S. O. 153, A. G. O., June 30, 1879.

STORROW, S. A., Major and Surgeon, Fort D. A. Russell, Wyo. T. Granted leave of absence for one month on surgeon's certificate of disability, with permission to leave the Department. S. O. 54, Dept. of the Platte, June 25, 1879.

JANEWAY, J. H., Major and Surgeon. Assigned to duty temporarily, as Post Surgeon at Fort Columbus, N. Y. H., in addition to his duties at Fort Wood. S. O. 105, Dept. of the East, June 30, 1879.

NORSON, Wm. M., Major and Surgeon. Relieved from duty with the Army Medical Board, in session in New York City, and assigned to duty as Post Surgeon at Fort Columbus, N. Y. H., relieving Surgeon C. B. White. S. O. 150, C. S., A. G. O.

GINSON, J. R., Major and Surgeon. Granted leave of absence for four months. S. O. 150, A. G. O., June 26, 1879.

CARVALLO, C., Capt. and Asst. Surgeon. Granted leave of absence for six months. S. O. 150, C. S., A. G. O.

KIMBALL, J. P., Capt. and Asst. Surgeon. Relieved from duty at Fort Columbus, N. Y. H., and assigned to duty as Attending Surgeon at the Headquarters, Military Division of the Atlantic and Dept. of the East. S. O. 105, C. S., Dept. of the East.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending July 5, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox	Yellow Fever.
June 28, 1879.	0	5	81	3	34	22	12	0
July 5, 1879.	0	4	59	4	32	15	5	0

PHYSICAL EXAMINATION OF SEAMEN.—In order that owners of American vessels may insure the services of healthy seamen, the Marine Hospital Service has announced in a circular that it will grant facilities for the proper physical examination of crews at all ports where medical officers of the Marine Hospital Service are stationed. Such officers will, upon the application of any U. S. Shipping Commissioner, or of the master or owner of any vessel engaged in the coasting trade, examine physically any seaman or seamen, and give a certificate as to their fitness or otherwise, without charge.

OFFICERS OF THE ARKANSAS MEDICAL SOCIETY.—*President*—E. T. Dale, M.D., of Texarkana; *First Vice-President*—W. M. Lawrence, M.D., of Batesville; *Second Vice-President*—I. B. Cummings, M.D., of Forest City; *Third Vice-President*—Albert Dunlap, M.D., of Fort Smith; *Fourth Vice-President*—J. T. Hamilton, M.D., of Pine Bluff; *Secretary*—R. G. Jennings, M.D., of Little Rock; *Assistant Secretary*—L. P. Gibson, M.D., of Little Rock; *Treasurer*—A. L. Breyssacher, M.D., of Little Rock; *Librarian*—J. H. Lenow, M.D., of Little Rock.

The next annual session of the Society will be held at Little Rock, on the first Wednesday in May, 1880, beginning at 11 o'clock A.M.

"PUT IT ON AT ONCE."—A loose red woollen flannel shirt should be worn next the skin, both summer and winter. It should be "loose," so that its moving upon the skin may keep up a good circulation there; "red," because white flannel pulls up, becomes stiff, and impervious; "woollen," because woollen flannel conveys the perspiration from the *under* to its *outer* surface, where either the cotton shirt absorbs or the air dries it without injury to the body. On account of these properties, sailors wear red woollen flannel even during midsummer in hot countries. Of course, a very thin material should be worn in summer.

GOLD-PLATINUM STAINING IN MICROSCOPY is brought forward and much recommended by Dr. W. R. Weisger, of Manchester, Va., as a new and excellent staining for demonstrating the epithelium of the lungs and other organs, endothelium of blood-vessels, muscular fibres of arteries, etc. The specimen, being appropriately prepared, is placed in a solution of equal parts, a one per cent. solution of platinum chloride and a one-half per cent. solution of gold chloride for a few minutes, till it becomes a pale straw color. Then put it in a tumblerful of distilled water, acidulated by a few drops of formilic acid, and expose to a bright sunlight. It must be watched, as complete staining usually takes place in less than three hours, even in July, August, and September.—*Trans. Med. Soc. Va.*, 1878.

CHLORAL HYDRATE IN DIPHTHERIA.—Prof. von Rokitsansky reports three cases of diphtheria, in which the local application of a fifty per cent. solution of chloral had a most striking effect on the local powers, although the usual remedies had previously proved entirely inefficacious. The solution was painted on every half hour. The pain produced was not very intense, but each application was followed by salivation. After a few applications the membrane could easily be removed, and delicate granulations could be seen in the reddened base. In two of the cases the membranes had disappeared, and the raw surface had granulated in two days, and in the other the process had run its course in four days. As soon as the membranes disappeared a weaker solution was used.—*Allg. med. Cent.-Zeit.*

CREMATION.—I am too firm a believer in the immortality of the soul, to view with patience the inconsistency of those who behave over the dead bodies of their friends as if the immortal part were being laid away in the ground. The more I might love my dead, the less willing I should be to leave the fair form that had once held an immortal spirit to turn into putrid carrion under ground, and breed a myriad of loathsome creatures out of its own rottenness. The attempt to substitute the scientific, poetical, and rational system of cremation has my earnest sympathy. I pray heaven that it may be possible to commit my body or that of any of my beloved to the pure flame, that in one short hour will purge them of dross as gold is refined in the furnace seven times heated.—*Col. Olcott.*

PHYSICIANS FOR SICK CHILDREN.—The Board of Health has divided the city into forty-eight districts, to each of which has been assigned an assistant sanitary inspector, whose duty it is to visit tenement houses, with the view of prescribing for sick children and giving such other advice as will tend to prevent the infantile disorders usually occurring in the heated season. The physicians have been selected from a large number of applicants, are paid for their services, and are expected to perform their duties conscientiously and with satisfaction.

THE BULLETIN OF THE PUBLIC HEALTH.—That portion of the Act of Congress of April 29, 1878, which requires consular officers, or other representatives of the United States at foreign ports, to report the sanitary condition of and the departure of vessels from such ports to the Supervising Surgeon-General of the Marine Hospital Service, and so much of the act as requires that officer to frame rules and regulations, and to execute the said act, and to give notice to Federal and State officers of the approach of infected vessels, and furnish the latter with weekly abstracts of consular sanitary reports, has, by Act of Congress approved June 2, 1879, been repealed.

Original Lectures.

ON THE CAUSES OF PUS IN THE URINE,
 AND ON THEIR DIFFERENTIAL CHAR-
 ACTERS.

A CLINICAL LECTURE DELIVERED MARCH 21, 1879,
 BEING THE LAST DELIVERED BY THE LATE

CHARLES MURCHISON, M.D., LL.D., F.R.S.,

PHYSICIAN TO, AND SPECIAL LECTURER ON CLINICAL MEDICINE AT
 ST. THOMAS'S HOSPITAL, LONDON.

(Reported by A. CLIFFORD MERCER, M.D.)

The characters of the pus found in the urine are different in different cases. Sometimes, soon after micturition, when seen in a test-glass, the urine is in its upper part quite clear, while the pus which has deposited appears as a more or less creamy layer at the bottom. At other times, notwithstanding the urine has been passed for some little time, it is everywhere alike turbid with pus, which remains permanently diffused. The first urine is acid, and contains ordinary pus; the second is alkaline, more or less viscid and gelatinous, and contains altered pus.

Three tests are used to determine the presence or absence of pus in the urine: the heat and nitric acid, the liquor potassæ, and the microscope tests. The first, the ordinary test for albumen, produces in the first or acid urine a greater or less opacity in the clear portion, and a much more marked one in the creamy layer. A deposit of pus is at the same time distinguished from one of pale lithates, both of which appear alike to the naked eye, since the latter would be cleared up by this test. If the second or alkaline urine be heated, it becomes a little more opaque (phosphates being precipitated), when, if nitric acid be added, it becomes again a little clearer (the phosphates being again dissolved); so that the two leave its turbidity much as it was before, the pus remaining unaltered. If liquor potassæ be added to the acid urine, the pus becomes viscid and gelatinous, "ropy." (If the precipitate be phosphates instead of pus, this change does not take place.) In the alkaline urine this change has already been effected. With the microscope, which gives the best evidence, if pus be present, pus-corpuscles are seen, identical in appearance with white blood-corpuscles. How then can they be distinguished, you ask. They cannot be; they are, in fact, only white blood-corpuscles in the wrong place. If treated with a drop or two of acetic acid, the granular contents in each disappears, and in its place a nucleus, often three-lobed, is seen.

The pus in pyuria comes from five sources: I. The female genital organs; II. The urethra; III. The bladder; IV. The kidneys and ureters; V. Abscesses which burst into the genito-urinary channels.

I. *If the pus be from the female genital organs*, it is due to one or more of the principal causes: A, acute and chronic vaginitis (vaginal leucorrhœa); B, uterine leucorrhœa; C, ulceration of the cervix uteri; D, cancer of the uterus; E, lochial discharge; F, an abscess, as one due to pelvic cellulitis, bursting into the genital organs. These are distinguished from other causes by: 1, the clinical history and the symptoms of one or more of these affections; 2, the microscopical examination of the urine, in which may be found pavement-epithelium from the vagina, cylindrical epithelium from the uterus, or cancer structure; 3, a purulent discharge independent of micturition; 4,

the absence of pus from the urine when drawn off directly from the bladder by a catheter.

II. *If the pus be from the urethra*, having special reference to the male, most of it comes away just before the urine in micturition; it is also discharged in the intervals between the micturitions, and the urine is usually acid. The causes are: A, Gonorrhœa; B, an abscess of the prostate; C, an abscess of Cowper's glands, or of the perineum opening into the urethra. A. *Gonorrhœa* is distinguished by: 1, great pain and burning in the urethra during micturition; 2, redness, swelling, itching, and burning at the meatus; 3, the appearance of pus at the meatus when the glans penis is gently pressed between the thumb and fingers. B. *An abscess of the prostate* is distinguished by: 1, pain which is present not so much during as just at the end of micturition; 2, swelling and tenderness of the prostate discoverable by rectal examination; 3, the condition of the prostate, which enables the physician by squeezing it to force pus and microscopic calculi* along the urethra and out of the meatus. According to Sir Henry Thompson, an abscess of the prostate may give rise to inflammation extending back into the neck of the bladder, accompanied by symptoms resembling those of stone, such as great frequency of micturition, pain following micturition, and referred to near the lower end of the penis, a little blood occasionally with the last drops of urine, an alkaline reaction of the urine which is turbid with altered pus, an exaggeration of all these symptoms when the patient is exercising or moving about. Such a condition is distinguished from stone by: a, the absence of any history of the descent of a calculus; b, more or less discharge from the urethra during the intervals between micturitions, but perhaps appearing only on squeezing the glans penis or urethra; c, often a history of gonorrhœa; d, swelling and tenderness of the prostate; e, the absence of a stone in the bladder, determined by the sound.

C. *An abscess in Cowper's glands or the perineum* is detected by local examination.

III. *If the pus be from the bladder*, most of it comes away at the end of micturition; it is altered, viscid, and like "ropy mucus," due to the alkaline condition of the urine; the urine is usually more or less ammoniacal, fetid, and deposits crystals of triple phosphates; there is more or less pain in the region of the bladder over the pubic bones, which is increased according to the disease present, sometimes before and sometimes after micturition, and which is often accompanied with tenderness in the same region, especially when the bladder is full of urine; and there is increased frequency of micturition. The causes are: A, cystitis; B, calculus; C, new growth. A. *Simple cystitis*, independent of calculus or new growth, is distinguished by: 1, pain, which is severest just before micturition when the bladder is full, and which is relieved by emptying the bladder; 2, hæmaturia only in rare cases, excepting when the disease is unusually acute or the result of an injury; 3, the symptoms of the primary trouble of which cystitis is really only a symptom, such as, a, the retention of urine by a stricture, an enlarged prostate, by a stone in old people, by fevers paralyzing the muscular coats of the bladder, or by paraplegia; b, gonorrhœa extending backward to the bladder; c, poisoning by cantharides, or by morbid states of the blood, as occurs in gout (gout being the cause of most "idiopathic" cases); 4, the absence of symptoms specially characteristic of stone or new growth.

* Hilton: Guy's Hospital Reports, series III, vol. xii.

B. *Calculus* is distinguished by the symptoms of the accompanying cystitis, and by: 1, pain, which is severest at the end of micturition and for some time after (because then for a time, when the bladder is empty, the stone comes in contact with the sensitive mucous lining), and which is more distressing than the pain in simple cystitis, and referred to the glans penis about one inch from the meatus; 2, hæmaturia very commonly in small quantity, so small often as only to be detected by the microscope, which is increased by violent exercise; 3, increased frequency of micturition, which is more noticeable during the day when the patient is moving about than it is during the night (the reverse being true in prostatic stricture); 4, sometimes a sudden stoppage in micturition due to the stone acting as a ball-valve in the bladder opening of the urethra; 5, in a great number of cases a previous history of nephritic colic, a severe pain shooting from one kidney down to the testicle or penis, retraction of the testicle, attended with rigors and vomiting, nausea, pallor, a quick, feeble pulse, intermittent pyrexia, and sometimes swelling of the testicle, all suddenly ceasing after the passage of the stone into the bladder; 6, the passing of a stone, red sand, or gravel in the urine; 7, the presence of a stone determined by a sound.

C. *New growths* originating in the bladder, or penetrating it from without, either exciting secondary cystitis or ulcerating, are distinguished by: 1, paroxysms of severe lancinating pain quite independent of micturition (in villous disease, however, there need be no pain if the urethra be not blocked by a blood-clot); 2, hæmaturia, irrespective of exercise, which is irregular, coming on at long intervals, or being very persistent, and is sometimes very copious, especially in villous disease, in which it is dangerously so; 3, the presence in the pus of epithelial cancer-cells, or in villous disease, villous processes; 4, cachexia and emaciation; 5, the absence of stricture, prostatic disease, and other causes of retention; 6, possibly a hard, irregular, tender tumor, which can be felt by the rectum or vagina; 7, possibly enlarged glands in the groin, or the evidence of new growths in distant parts of the body; 8, in the absence of an appreciable tumor, and the presence of symptoms resembling those of stone, the evidence furnished by the sound, which may detect a thickening of the bladder wall, but not the presence of a stone.

IV. *If the pus be from the kidneys or the ureters*, it is at first uniformly mixed with the urine, but, after a little, settles as a creamy layer, leaving the urine above clear. The urine is acid, as a rule, but may become alkaline by standing too long after micturition, or be alkaline from the first if pus comes from the bladder as well as from the ureter, and, when alkaline, is turbid with altered pus, which does not settle. There is pain and tenderness over the kidney and about the crest of the ilium, which extends down to the bladder and penis (pain alone over the kidney may be a symptom of bladder disease only; but tenderness there is very significant). A tumor in the kidney region may be sometimes detected, and should in all cases be looked for. Increased frequency of micturition may be present, but without pain in the bladder, either before or after micturition. The causes are: A. Certain rare cases of acute nephritis. B. Calculous pyelitis. C. Tubercular pyelitis. D. Pyelitis from obstruction of the urinary passages.

A. *Certain rare cases of acute nephritis*.—These are such as sometimes supervene in cases of carbuncle, boils, erysipelas, acute fevers, parturition, or pyæmia, and also occur in rare instances in which gonorrhœa spreads

upward as acute pyelitis as well as acute nephritis, and are recognized by: 1, the slight quantity of pus; 2, the degenerate products of nephritis, such as epithelial pus or hyaline casts, etc.; 3, the previous history of smokiness or other evidence in the urine of the existence of acute nephritis; 4, a quantity of albumen much too great to be accounted for by the amount of liquor puris; 5, general dropsy not uncommonly; 6, uremic symptoms possibly, such as headache, retching, drowsiness, coma, or convulsions; 7, the absence of any tumor to be detected externally; 8, a dry skin; 9, the previous history of one of the above causes.

B. *Calculous pyelitis* is distinguished by: 1, a previous history, though not always, of nephralgia, a pain extending from the kidney to the testicle, penis, vagina, or thigh, attended with rigors, nausea, vomiting, frequent micturition, hæmaturia, retraction or swelling of the testicle, pallor, a quick, feeble pulse, and some fever, perhaps; 2, pain and tenderness, or simply a burning or aching, not necessarily in all cases, however, more or less constant in the region of one kidney or both, which is increased by much exercise and fatigue, or may be present only during fatigue; 3, hæmaturia, especially when the calculus is composed of oxalate of calcium, and in any other case after violent exercise, while microscopic blood is usually present at other times; 4, a variation in the quantity of pus from day to day; 5, the absence of casts; 6, crystals of uric acid, or, not uncommonly, of oxalate of calcium; 7, a tumor in certain cases, not in all, more or less painful, in the kidney region, which enlarges when the quantity of pus in the urine diminishes, and becomes smaller, or disappears, when the quantity suddenly increases; 8, attacks of intermitting pyrexia, occasionally ushered in by rigors, and followed by profuse sweating, which are most severe when the tumor is largest; 9, the absence of dropsy and other signs of acute nephritis, though the patient may ultimately die of uræmia, due to the wasting of the secreting tissue of the kidney; 10, its duration, which may be a fair lifetime (one case lasted forty years), or may end favorably, by the stone passing into the bladder, or becoming encysted.

C. *Tubercular pyelitis* is distinguished by: 1, the absence of any history of renal colic; 2, a constant, dull pain in the back, over one kidney or both, with exacerbations when the ureter becomes blocked, and which is accompanied with tenderness over only one kidney, in nine cases out of ten; 3, hæmaturia not uncommonly, which is slight, and may be the earliest symptom, and then disappear; 4, the unvarying, or steadily increasing, quantity of pus in the urine; 5, the absence of casts from the urine, and the presence often of amorphous granular matter insoluble in acetic acid, of particles of caseous matter, or fibres of connective or elastic tissue; 6, the absence of crystals; 7, the formation, if the ureter be blocked, of a tumor, which may point externally, or even stretch across the middle line (of sixteen cases, a tumor formed in seven); 8, persistent pyrexia, usually intermittent and hectic, with night-sweats; 9, as a rule, persistent and rapid emaciation, but the patient may even gain flesh under treatment; 10, signs of tubercle in the lungs, bowels, testes, prostate, vertebrae, or elsewhere; 11, the fact that it occurs more frequently in males than in females; 12, the absence of dropsy and any tendency to uræmia, the patient dying from exhaustion; 13, the rapid progress of the disease, which rarely lasts two years.

D. *Pyelitis from obstruction of the urinary passages* is distinguished by: 1, the history and the symptoms of a primary obstructive disease, as cancer of the uterus,

stricture, enlarged prostate, hydatids in the pelvis, etc.; 2, constant aching pain and tenderness in the back, over one kidney or both; 3, copious urine of low specific gravity, with little urea or albumen; 4, a varying quantity of pus in the urine, possibly with casts, consisting of pus-cells from small abscesses in the substance of the kidney, or with an alkaline reaction due to the concurrent cystitis; 5, very commonly paroxysms of intermittent pyrexia; 6, the great tendency to headache and uremic symptoms.

V. *If the pus be from an abscess bursting into the urinary passages*, its places of origin may be very various, some of them being: A. In rare cases, empyema. B. A tropical abscess of the liver. C. A psoas abscess. D. A prostatic abscess. E. Pelvic cellulitis after or independent of parturition. The urine is usually acid, and the pus falls as a creamy layer. Further, the diagnosis depends upon: 1, the clinical history previous to the pyuria; and, 2, the concomitant symptoms and signs of the primary disease.

Original Communications.

REMARKS ON OVARIOTOMY.

VALUE OF EARLY RECTAL USE OF QUININE AND OPIUM IN CONJUNCTION WITH FREE SUPPORTING DIET, AS MEANS OF DEFENDING THE SYSTEM AGAINST THE DANGERS OF THE OPERATION—ILLUSTRATED BY A SERIES OF SIX SUCCESSFUL CASES, THREE SINGLE AND THREE DOUBLE.

By NATHAN BOZEMAN, M.D.,

SURGEON TO THE WOMAN'S HOSPITAL OF THE STATE OF NEW YORK.

WHEN Prof. Schroeder, a little more than a year ago, announced that under the antiseptic method of Mr. Lister he had just completed a series of fifty ovariectomies, with the result of forty cures and ten deaths (80 per cent.), and that thirty-three of these cases, with a loss of only one, were treated in the Berlin Lying-in Hospital—notoriously bad in all its sanitary appointments—there was a feeling of general satisfaction among gynecologists as to the value of antiseptic treatment, and a disposition manifested more than ever before to give it a fair trial. It is true that just as good, and even better, results than these had been secured in Great Britain, especially in the practice of Mr. Keith, before the general employment there of antiseptics; but in Germany nothing entitled to comparison with these results of Prof. Schroeder had previously been witnessed. Dr. Oldshausen, a few months later, in a letter to Mr. Spencer Wells, stated that the mortality of ovariectomy in Germany, before the adoption of antiseptics in the practice of Esmarch, Hegar, Schroeder and himself, was thirty-three deaths out of sixty-five cases, and since the adoption of antiseptics, thirty-three deaths out of one hundred and fifty-five cases. The exultation, therefore, over the unprecedented success of Prof. Schroeder was not surprising. In his series of fifty cases he had at one time twenty-three consecutive successes, which was also considered very extraordinary for German practice. But Mr. Wells, in England, long before this, without antiseptics, had a similar series of twenty-seven successful operations.

Satisfactory, however, as were the above results of

ovariotomy in Germany under the antiseptic method of Mr. Lister, they have since been so far eclipsed in brilliancy in Scotland by Mr. Keith, through the same protective method, as to be almost lost sight of. Mr. Keith states (*British Med. Jour.*, Oct. 19, 1878) that out of fifty cases treated according to the antiseptic method forty-eight were cured (96 per cent.); that the two deaths occurred in the first eight cases, thus showing the unprecedented run of forty-two successive successes, an achievement gynecologists for all time to come might be well content to emulate.

His convictions on the soundness of the theory upon which the antiseptic treatment is based, and the emphasis which he gives to the above results, Mr. Keith sets forth in the following significant words: "Since 1876 every operation has been performed with all Mr. Lister's care, under the carbolic acid cloud, and I shall never go back to the old way."

This triumph, therefore, of Mr. Keith, and his recognition of the value of the antiseptic method, may be accepted, I think, as conclusive evidence of the entire correctness of the practice. But in doing this, the fact should not be lost sight of that Mr. Keith still insists upon the greatest care in performing the operation, and the closest attention afterward to the details of surgical treatment. He says that, at the time of commencing antiseptics, in 1876, he had reduced his mortality to about ten per cent. through the improved sanitary condition of his top-flat hospital, and his employment of the actual cautery with the drainage-tube. Yet it is evident enough, from the importance attached to the two factors previously named, that he believed they contributed no small share to the result claimed. While he is willing, with the increased advantages of the antiseptic method before him, to exchange the actual cautery for the ligature, and to dispense with the drainage-tube, he still insists upon the importance of effectually controlling hemorrhage, and of taking time to wipe out thoroughly the peritoneal cavity. It is, as he further remarks, mainly in the class of adherent tumors, accompanied by a feeble state of health and too long delay of the operation, that the greatest difficulties in treatment are experienced, and to overcome which something in addition to antiseptics is still needed to insure further success in this direction.

Now, Mr. Keith having remarked that previous to his adoption of the antiseptic method of Mr. Lister, in 1876, he had reduced his mortality to ten per cent., it is to be inferred that further improvement of the operation in his hands must have for its object yet the diminution of the mortality of this seemingly small class of cases. The question then may be asked, how much has been gained already by the employment alone of antiseptics? According to the recent experience of Mr. Keith the answer is about six per cent. Therefore, if it be true his aggregate success with antiseptics is now ninety-six per cent., then there would seem to be but little need of any one else attempting to further improve the operation, since it is hardly probable that the actual mortality can ever be brought within narrower limits than four per cent.

Such is truly a very encouraging picture of the advanced state of our knowledge and practice with regard to the operation of ovariectomy. But Mr. Keith's success is exceptional, as no one for a moment, I imagine, will question. No other surgeon has attained anything like it in a large run of cases. I doubt whether at the present moment the average mortality of this operation in the hands of all surgeons is below 20 per cent. That the Lister method has contributed a large share toward bringing about

even this gratifying result there can be no doubt, and it is from a better and more general understanding of this and other important principles of practice yet to be mentioned that further diminution of our general mortality may be expected to follow.

It is, therefore, the general mortality of 20 per cent., instead of 4 per cent., as shown by the individual death-rate of Mr. Keith, that is to be lessened by improved methods of treatment, and the question now is, how can this be best attained? Death results, in about seven-eighths of all cases, from shock or collapse, hemorrhage, exhaustion, peritonitis, and septic intoxication, pyæmia, and to a large extent within the first three or four days. The late Dr. Peaslee, in speaking of the causes of death after the operation of ovariectomy, says: "Thus shock and collapse, when fatal, prove so in more than one-half of the cases within forty-eight hours; and in more than two-thirds, within ninety-six hours. About one-half of those who die of hemorrhage perish within twenty-four hours, and seven-eighths within seventy-two hours. Acute peritonitis proves fatal in twelve to twenty-four hours, and on to the eighth day; nearly one-fourth of the whole number dying on the third day alone, and nearly two-thirds of the whole within the first seventy-two hours. Asthenic peritonitis proves fatal from the ninth up to the twenty-first day, or even later."

Now, what are the conditions of the system before and after the operation of ovariectomy that favors death from the above causes? And what is the proper plan of treatment to curtail or eliminate liability to the same?

Conditions of the system.—With regard to the pathology of morbid growths of the ovaries, whether cystic or solid, benign or malignant, it is by no means clear and satisfactory. As to the views generally entertained upon the subject with regard to associated conditions of the system in different stages of the development of these growths, they must undergo, it seems to me, a very considerable modification before we can expect to derive the fullest benefits from constitutional and surgical treatments. But I do not propose here to discuss these points, but simply to state, in the most concise manner possible, my own convictions, which may or may not be correct. They are presented in the following epitome:

First. That the conditions of the system favoring the idiopathic development of ovarian growths expose both ovaries alike to attack, but that oftentimes these growths are induced without such previous conditions of the system, through dislocation or imprisonment of one or the other, or of both ovaries, in a state of hyperæmia or anæmia.

Second. That the morbid processes underlying the development of ovarian growths, in whatsoever way produced, soon lead to disturbance of innervation and nutrition of the entire system, and thus cause gradual impoverishment of the blood—general anæmia.

Third. That the general anæmia arising from the development of ovarian growths, call it, if you please, simple idiopathic or pernicious, is always progressive, and that the stages of growth and development ordinarily recognized only represent so many degrees of advancement toward a fatal termination, which certainly comes sooner or later, unless checked by the resources of surgical art.

Fourth. That the general anæmia accompanying ovarian growths is usually attended in the earlier stages with a well-preserved outward appearance of the body: but that such adipose symmetry—*embon-*

point—associated as it is with deficiency of red blood-globules, betokens discrasia rather than robust health.

Fifth. That the general anæmia of ovarian growths, when attended with emaciation, as in the latter stages, is pernicious in the highest degree, owing to the rapidly increasing abstraction of important elements from the blood, and to other functional disturbances arising from mechanical pressure.

Sixth. That inflammatory affections, whether of idiopathic or traumatic origin, occurring in any stage of the general anæmia attending ovarian growths, tend always to low and persistent forms; and that the attending fever, be it due or not to the introduction of a pyrogenic, phlogogenic, pyogenic, or septigenic material into the blood, is almost, if not always, in a corresponding degree asthenic in type.

Seventh. The seemingly necessary corollary from the foregoing propositions is, that the surgeon should strive to counteract the evil tendencies of the general anæmia of ovarian growths; to husband and strengthen the powers of the system during its progress; to remove the morbid growth, as experience justifies, before or as soon after the emaciation appears, as the diagnosis can be determined; to avoid all depletory or depressing influences; and to treat the accompanying inflammation, whether acute or chronic, through all its stages, by continuous and persistent support of the vital forces, leaving the attending fever to take care of itself.

Proper plan of treatment.—The object of any plan of treatment, before and after the operation of ovariectomy, is to prevent death mainly from pernicious anæmia, shock or collapse, hemorrhage, exhaustion, peritonitis, septic intoxication, and pyæmia. Shall this be done by means of the ordinary antiphlogistic measures, including blood-letting, depressants, refrigeration, low diet, etc.? or shall it be by an opposite course, and by invigorating the system, restoring the lost elements of the blood, and maintaining as nearly as possible a health standard of the vital forces?

1. *Antiphlogistic treatment.*—With regard to antiphlogistic measures to control peritonitis, the great bugbear of ovariectomy, it is usually insisted upon that they should be employed early and vigorously, because by far the largest proportion of the fatal cases terminate within the first three or four days after the operation. So also must they be employed, if employed at all, to meet any of the other emergencies before enumerated, which allow but little time for hesitation. It is very easy for writers upon the subject to say that when peritonitis or septicæmia shows itself within the first few days after ovariectomy, with a pulse varying from 120 to 140, and a temperature from 102° to 104° F., that the patient should be watched and the threatening progress energetically combated by means of general bloodletting, leeching, opiates, fomentations, aconite, veratrum viride, ice-caps to the head, and ice-bags and cold water affusions over the abdomen. But what has been the success obtained by this plan of treatment? Judging from the experience of those who have given it a fair trial, there is for the future no great encouragement, I conceive, to adhere to it.

It is not my purpose here to enter upon a study of the various measures above enumerated. I shall speak only of the use of ice and cold water affusions, as means of controlling high temperature and lowering the pulse. As viewed from my standpoint, I see no great objection to the cautious application of either ice or cold water affusions to the head where the indications justify it, but as applied to the abdo-

men the question is quite another thing. I seriously object to the application of ice or cold water affusions to the abdomen, either as a part of the so-called anti-phlogistic plan of treatment, or of the supporting plan of treatment, since their depressing effect upon the heart's action is oftentimes so great and uncontrollable as to immediately endanger life, or remotely to lead to suppuration within the peritoneal cavity, pyæmia, pleuro-pneumonia, and perhaps other complications. They unquestionably reduce the temperature, and lower the frequency of the pulse to almost any desired extent for the time being, but the vital forces are weakened and the integrity of remote organs is impaired by their use, especially when long continued. Therefore, notwithstanding the warm attestations as to the value of these resources by English and German ovariologists, I feel constrained to regard them as more powerful for evil than for good.

In our own country these expedients have also been resorted to with more or less flattering commendations. Dr. T. G. Thomas, whose large experience entitles his opinion to much weight, recommends cold water affusions over the abdomen, applying them at a temperature varying from sixty to ninety degrees, with the patient lying upon what is known here as Kibbe's cot. In a paper read by him before the New York Academy of Medicine, entitled: "The Most Effectual Method for Controlling the High Temperature occurring after Ovariectomy" (*New York Med. Journal*, August, 1878), he contrasts cold affusions with large doses of quinine and salicylic acid, and its salts, and expresses his convictions of the superiority of the former in the strongest terms.

Dr. Thomas assumes that prolonged high temperature after the operation of ovariectomy, occurring in whatsoever way, leads to disorganization of the blood, and serious impairments, or tissue changes in the cardiac and nervous centres. These results, he thinks, can be largely prevented by resorting to cold-water affusions over the abdomen, which keep the temperature and pulse from the beginning below 100° F. and 110 respectively, a result which can only be partially obtained, if at all, with large doses of quinine, or the salts of salicylic acid. As to the end sought to be attained, he says: "In adopting this plan of treatment after ovariectomy, and as I have in several cases done after parturition, I did not propose by it to check peritonitis or to cut short septicæmia, the great evils to be feared at the time. My object was to rob these diseases of one of their chief weapons of destruction—hyperpyrexia—and thus to resist the primary assault in the hope of bearing up against a more prolonged, though less violent, siege."

Dr. Thomas reports, in support of his views, eight cases, one of which was peritonitis resulting from a cause other than that of ovariectomy. Out of this number six recovered. Of the two cases terminating fatally, there was in one, as revealed by the autopsy, "internal peritonitis, with several points of localized gangrene of the intestine;" and, in the other, "evidences of peritonitis, pleurisy with effusion, and pneumothorax," which are assigned as the immediate causes of death—on the twenty-sixth and fourteenth days respectively. Dr. Thomas also refers incidentally to two other cases of ovariectomy, occurring some time before, which terminated fatally under the same plan of treatment; but the particulars of those cases he does not give, further than to say they illustrate "the lessons taught by the two first recited, namely: uniform capacity of this method of refrigeration for maintaining a nearly normal temperature, even while a fatal disorder, one of the most striking character-

istics of which is hyperpyrexia, still steadily marches on to a fatal issue."

Of the eighth reported case, he speaks of the depressing effect of this treatment upon the heart's action, as shown by the irregularity and intermittency of the pulse, with coldness and blueness of the hands. The patient, however, a girl sixteen years old, showed no other signs of being unfavorably affected by the douching, and made a good recovery.

With regard to nourishment, in connection with cold affusion over the abdomen, Dr. Thomas only speaks of it incidentally in cases one and seven as being by enemata, twelve and four days respectively. In the former he employed milk by intra-venous injection four times, but to no effect further than to assist in sustaining life, as was supposed, to the twenty-sixth day. From this it is to be inferred that low diet was the rule for a few days at least, since it usually forms an important feature in the anti-phlogistic plan of treatment to which cold affusion properly belongs. Of the views upon low diet entertained by some of the highest authorities who have written upon the subject, the late Dr. E. R. Peaslee gives a faithful reflex in the following words:

"Very little nourishment is to be given the first seventy-two hours. I prefer to continue the milk porridge used before the operation. I. B. Brown gives barley-water, or iced milk, or weak broths, and sometimes also a mutton-chop on the third day. Mr. Wells and Dr. Keith give barley-water mainly, but the latter gives no food at all till after flatus passes *per rectum*—only a little cold water, or a few sips of very hot water. He gives soup and brandy enemata in the feeblest cases. Dr. Roberts advises as little food as possible the first forty-eight hours to obviate sickness and vomiting. No solid food is to be given, as Dr. Clay judiciously advises, until asked for by the patient. If the stomach is irritable, the nourishment, as well as the opiate, is to be administered *per rectum*, in which case beef-tea is a good substitute for the milk porridge."

Now, if the experience of Dr. Thomas with cold water affusions over the abdomen, based upon the results of the eight cases reported in his interesting paper, proves anything, it is the full recognition by him of the great value of the method from the following considerations:

1. That sulphate of quinine and the salts of salicylic acid, if antipyretic at all, are only so slightly, so as not to entitle them to any confidence in the treatment of peritonitis and septicæmia resulting from ovariectomy.
2. That cold-water affusion over the abdomen is antipyretic in the highest degree, and deserves to take precedence over all other known methods as a reliable means of controlling the peritonitis and septicæmia, on account of the simplicity of the method and the ease with which it can be carried out upon Kibbe's cot.
3. That the dangers of cold-water affusions over the abdomen, if there be any incident to the practice, are so slight as only to require ordinary precautions for their avoidance, and that they should not stand in the way of the employment of so valuable a method to control the hyperpyrexia of peritonitis and septicæmia.
4. That cold-water affusions over the abdomen, while they are not directly curative in themselves of peritonitis and septicæmia, yet are indirectly so to a higher degree than any other known agent, by preventing disorganization of the blood and serious impairment of the vital functions.

How far these views of Dr. Thomas upon cold-water affusions as an antipyretic are supported, the statistics of his eight reported cases must answer. A mortality of twenty-five per cent., as shown by this exhibit, is certainly not promising when compared with Mr. Keith's rate of ten per cent., secured without either antiseptics or cold-water affusions. I do not know what Dr. Thomas's further experience in the use of cold affusions has been, nor do I know how often it has been employed by other operators since his interesting paper was published. I have employed the method only once, which was in the Woman's Hospital several months previous to the time he read his paper before the Academy of Medicine. From the little experience which a single case gave me, I was convinced that the practice was not only heroic but dangerous, and opposed to sound principles of surgery. The report of the case (1) is appended to these remarks, which was one of double ovariectomy. The after-treatment consisted in free nourishment by the mouth from the beginning, and of opium by the rectum to control pain. At the end of thirty-six hours the pulse had reached 120 and the temperature $103\frac{1}{2}^{\circ}$ F. Associated with these indications there were tympanitis, tenderness over the entire abdomen, thirst, and dryness of skin. Under these circumstances the patient was put upon Kibbe's cot and douching of the abdomen with water at 67° F. commenced. At the end of seventy-one hours, when eight douches, varying from 65° to 75° F., had been given, there was no abatement of the acuteness and intensity of the peritonitis. Pulse 126 and very feeble, temperature $104\frac{1}{4}^{\circ}$ F. Beginning now to lose confidence in the method, and necessarily feeling anxious for the safety of my patient, I supplemented the opium per rectum with eight grains of sulphate of quinine, to be repeated every six hours. The process of douching, with no abatement, however, was continued under the direction of the house-surgeon, Dr. J. L. Perry, whose care and attention were unremitting. At the end of eighty hours, when sixteen douches in all had been given, the last eight within eight hours, the temperature stood at $103\frac{3}{4}^{\circ}$ F., just one-quarter of a degree less than at the beginning. A few hours after the last douche, at $6\frac{1}{2}$ o'clock A.M., I made my visit, and found the patient in a condition of collapse, as I supposed. She seemed to be chilled through, so to speak; was cyanosed and almost pulseless. The application, however, of cans of hot water about the chest and extremities, and the free administration of whiskey, were soon followed by reaction and disappearance of the above threatening symptoms.

The cold affusion was discontinued, and in its stead increased nourishment and stimulation by the mouth were ordered, in connection with quinine and opium by the rectum. At the end of ninety-six hours, when the patient had taken forty grains of quinine, thorough *cinchonism* manifested itself, and her pulse was 104 and temperature $100\frac{3}{4}^{\circ}$ F. From this time on the temperature rose but little above 101° F., and this only for a few days. Her convalescence, however, was slow, lasting nearly three weeks, owing, no doubt, to inflammatory products shut up in the peritoneal cavity, as the result, I fully believe, of the depressing influence produced upon the vital forces for so long a time by the cold affusion, and my failure to employ quinine at the outset of the after-treatment. But my treatment of this case was no more heroic than that adopted in the eight cases reported by Dr. Thomas. The difference in result being simply that my patient narrowly escaped a fatal issue from exhaustion and depression of the heart's

action without permanent reduction of temperature at the end of the fourth day; while one of his, after having the temperature for twelve days kept at a point below 100° F., discharged through the abdominal incision more than a pint of pus on the fourteenth day, and finally died on the twenty-sixth day, leaving evidences of extensive peritonitis and gangrene of the bowel; and the other, after the temperature had been lowered from 104° to about 101° F., suffered from an attack of acute pleuritis, with effusion on the fifth day. The increased temperature of the latter complication was treated by continued douching until the eighth day after the operation, when recovery from its effects was pronounced. The case, however, terminated fatally on the fourteenth day, showing at the autopsy, as before mentioned, peritonitis and pleuropneumonia, with effusion.

May not these embarrassing complications encountered by Dr. Thomas and myself be the legitimate fruits of the employment of cold-water affusions over the abdomen? And may we not in attempting, with so powerful an agent, to disarm peritonitis and septicaemia of their dire phenomena—high pulse and high temperature—on the one hand, directly favor or produce, on the other hand, the identical complications and lesions mentioned? In short, may we not, in thus attempting to steer clear of Scylla, run squarely against Charybdis? These are my convictions, and I shall not rest content upon the subject until further statistics open up a more encouraging prospect than that viewed from my present standpoint.

2. *Preparatory and supporting treatment.*—Next let us turn our attention to the plan of preparing and supporting the system as a means of meeting and controlling the principal dangers of ovariectomy previously enumerated. This plan of treatment, according to my understanding of it, embraces all suitable articles of food which can be assimilated when introduced into the mouth and the rectum. Any form of stimulant which the system may require or tolerate, and any kind of medicine which special indications may demand. The plan properly resolves itself into two stages: first, before the operation; and second, after the operation.

1. *Before the operation.*—This stage of the treatment may be supposed to be coextensive with the existence of the morbid growth, but for present purposes it is limited to the week immediately preceding the day set for the operation. During this time the secretions of the body should be regulated as far as practicable, the bowels kept in a soluble condition, the circulation equalized, pain or nervous irritation controlled, the system nourished, and the blood infused, so to speak, with new life.

The means for accomplishing all these ends readily suggest themselves. A mild cathartic every day, or every other day, and an active one the night before the operation; daily tepid baths followed by rubbing the body with emollients, of which vaseline answers an admirable purpose; anodynes or bromide of potash; easily digested and nourishing food of any kind, with wine, ale, porter, brandy, etc., as may be desired or found useful; tonics, of which the tincture of iron, salicin, and quinine are the best.

With regard to the last named medicines, the iron and salicin are given together three times a day in doses of 15 drops of the former and 15–20 grains of the latter. When this form of iron causes headache, as happens sometimes, or otherwise is not borne, then substitute iron by hydrogen or carbonate of iron, or give salicin alone. The quinine is reserved for the last, when 15 grains are given the night before the

operation, and 10, with a grain of opium, the following morning, after the lower bowel has been emptied by a lavement of warm water containing a small quantity of castile soap and common salt.

2. *After the Operation.*—The stage of active treatment immediately after the operation is supposed to continue until all dangers are passed—one week, more or less, according to circumstances. The faithfulness with which it is carried out rests not only in the convictions of the surgeon as to what is absolutely required, but in the ceaseless vigilance and assiduity of the nurses intrusted with his directions.

First, the remedial agents to be employed: These are principally quinine, opium, brandy, whiskey, champagne, and any other forms of medicine required or best suited to the individual case. After the patient has recovered from the anæsthetic, all sources of annoyance or direct irritation, of whatsoever nature, are to be avoided as far as possible, and none among them I conceive is more worrying than that of the hypodermic syringe. The use of this instrument I would therefore restrict to the narrowest limits, trusting to other modes equally efficacious for introducing morphine into the system. But can it be said that the stomach affords this facility to the desired extent? Certainly not. But this and the rectum together unquestionably do to a very high degree, not only as regards medicines, but also articles of food. When both of these fail, and the patient is *in extremis*, then the hypodermic syringe may play an important part in introducing into the system not only morphia, but quinine, brandy, or ether. The form of anodyne which I prefer to all others is Squibb's compound liquor of opium. It is more uniform and reliable in its strength than laudanum, and for that reason, if no other, is more valuable. The object to be attained by this preparation of opium is not only the control of pain, but the lessening of general reflex nervous irritation. It also antagonizes the unpleasant effects of quinine upon the brain, thus giving to the latter greater potency in controlling not only cardiac and pulmonary action, but the processes of disassimilation or tissue changes upon which depend, it is believed, the excessive body-heat. My rule now is to administer per rectum, as soon as the patient is removed from the operating-table to her bed, one drachm of the above preparation of opium with ten grains of sulph. of quinine in half an ounce of acidulated water. This will usually be found sufficient to lull the attending pain after the effects of the anæsthetic are passed. The dose is afterward reduced to half a drachm with the same quantity of quinine, and repeated every six hours. Should severe pains develop in the intervals, the hypodermic use of six to eight minims of Magendie's sol. of morphine is allowed. According to my experience, such emergencies arise only occasionally, and often not at all, in the entire after-treatment. This quantity of opium, about four and a half grains in the twenty-four hours, keeps the patient in a quiet, drowsy state, ready to take nourishment per orem and rectum at almost any moment, and again to relapse into the same somnolent state, seemingly without disturbance. It is seldom necessary to increase the dose of quinine mentioned. This quantity, forty grains in the twenty-four hours, with the twenty-five grains given the night and morning preceding the operation, will rarely fail to produce its specific effect within thirty-six or forty-eight hours, just at the time it is needed to infuse the blood with life-giving and life-saving qualities, and thus control or moderate the rise of temperature. I have seen as small a quantity as thirty-two grains of quinine, given in this

way, followed by thorough cinchonism, with almost immediate reduction of both pulse and temperature; but usually double or triple this quantity will be required to produce the desired effect. I am satisfied that the reason why those who have tried and condemned quinine as useless in controlling hyperpyrexia after ovariectomy, is because they have not commenced its use early enough, have not properly combined it with opium, or have not given it in sufficient quantities. The disadvantages of waiting until peritonitis and septicæmia are developed before commencing the use of the remedy, and the advantages of giving it early in combination with opium by the rectum, are so evident, it seems to me they require only mention here.

But quinine and opium are not the only remedies I give by the rectum after ovariectomy. Brandy, in doses varying from one to four drachms, at intervals of three hours, may thus be administered with the greatest advantage when the stomach is irritable and stimulation is called for.

Second, the kind of food to be employed after ovariectomy. The introduction of food into the system by the rectum—rectal alimentation—is of the greatest importance to insure continuous support of the vital forces, and the best results from quinine and opium as regards the control and moderation of fever. The articles best suited for this purpose are unquestionably beef-tea, mutton-broth, chicken-broth, and mashed beef. The last named I greatly prefer, as it far exceeds in efficiency any of the other forms of animal nutriment mentioned. It is prepared by first chopping up the beef very fine, say three pounds, and then putting the whole into a wooden bowl and mashing it with a pestle. Now cold water, say a teacupful, is added, and thoroughly incorporated with the mass. This being done, it is next placed in a cullender, and all the juice pressed or rubbed out with as much of the muscular fibre as will pass through the holes. Again the juice is placed in a fine wire strainer and thus cleared of all the larger particles of meat-fibre that would otherwise clog or obstruct the pipe of the syringe. Thus is obtained about sixteen ounces of juice, which is believed to contain the nutritive elements of about one-third of the three pounds of beef employed. For keeping, it should be set in a cool place or upon ice, and for use warmed over a spirit-lamp or otherwise. It may be administered alone or in combination with pancreatine. In the proportion of two ounces to one drachm of the latter an excellent emulsion is formed, which is about the quantity to be administered at a time. Its use should be commenced three hours after the first dose of quinine and opium, and it also is to be repeated every six hours. If it manifests any tendency to irritate the rectum, so as to provoke a discharge, twelve to fifteen drops of the preparation of opium indicated (liq. opii. comp.) must be added. In this event, the quantity of the latter used with the quinine is to be lessened in like proportion, unless there be a demand for more than two drachms in the twenty-four hours, which is hardly probable. When the necessity arises, brandy may be combined with the emulsion in quantity varying from one to four drachms. The emulsion may also be used as a vehicle for the quinine and opium instead of the acidulated water, using for the purpose half to one ounce. In this manner from eight to ten ounces of the emulsion are introduced into the system in twenty-four hours, equal to half a pound or more of beef.

Thus is rectal alimentation, medication, and stimulation gradually carried to the point of giving the greatest amount of nutrition and support.

But again, ingesta by the mouth, when it can be tolerated, is no less important than by the rectum. I only mention this function last, natural as it is, because it is so liable to be disturbed or interrupted at the outset of the treatment. The stomach, almost always irritable from the anæsthetic for the first six or eight hours, can only be made available for the introduction into the system of medicines and food under the most careful watching and with the greatest precautions. Too early resort to it for either purpose is highly prejudicial to success, and oftentimes leads to irreparable mischief. One cannot be too cautious, therefore, in selecting such articles, both of medicine and of food, as may be best adapted to the ends in view and in testing with them the strength of the stomach.

As regards stimulants, brandy, whiskey, and champagne are the best and most available. Whichever one may be selected, it is to be given in small quantities, and often repeated. When tolerance of the stomach is assured and necessity requires it, the dose can be gradually increased, but under all circumstances this must be done cautiously, otherwise much valuable time must be lost. The same thing is true of all medicines employed to meet special indications in the after-treatment.

Much discrimination is called for in selecting articles of diet and in regulating the quantities to be given. Rice-water, barley-water, milk, milk-and-lime-water, milk porridge, beef-tea, chicken-broth, and mutton-broth are the articles to be relied upon.

Of these, milk alone or milk with lime-water, or milk in the form of porridge, is by far the most valuable and reliable in the beginning of the after-treatment, and given with the same precautions pointed out with reference to the use of stimulants, it seldom fails to give satisfaction, especially when used supplementary to regular rectal alimentation. Beef-tea and broths are equally serviceable after a few days, and may be alternated with the milk, or given alone, according to the fancy of the patient or the wish of the surgeon to discontinue rectal alimentation. Given in teaspoonful or tablespoonful doses and repeated every half or every hour, considerable quantities of any one of the articles named may be given in the twenty-four hours without disturbing the stomach or seriously annoying the patient. The patient being constantly under the influence of opium, given by the rectum, sensitiveness, not only of the stomach, but of the entire alimentary canal is held in abeyance, and a state of almost continuous slumber is maintained. Borborygmus and tympanitis, usually so constant and persistent after ovariectomy, under the expectant plan of treatment, show themselves in this state of quininism and seminarcotism only to a very slight extent, and often not at all. These are advantages which cannot be too highly estimated in any course of treatment. The meteorism of typhoid fever, a like condition, my friend Dr. Alexander Hadden, of this city, informs me he controls with an equally high degree of certainty by the employment of salicylate of soda.

The prevention of shock after capital operations by previous administration of large doses of quinine, as claimed by Dr. Hunter McGuire, of Richmond, has its explanation no doubt in the profound and salutary effect which the remedy produces upon the cerebro-spinal and sympathetic nerve-centres. That shock from the operation of ovariectomy, attended with or without serious loss of blood, is a frequent cause of death, immediately or remotely, there can be no doubt. That quinine does prevent or lessen the tendency to

shock in capital operations in a marked degree, I am thoroughly satisfied from my own somewhat large experience with it years ago in the general practice of surgery.

AN UNIQUE CASE OF PUNCTURED FRACTURE OF THE BASE OF THE SKULL, WITH AUTOPSY.

By CORNELIUS WILLIAMS, M.D.,

NEW YORK.

On Tuesday, Nov. 19, 1878, S. A., a butcher, about 48 years of age, came into my service in the Out-Door Department of Mt. Sinai Hospital, with the following history:

On the Saturday previous, Nov. 16th, while hanging meat in Washington Market, he slipped and fell against the beam to which the iron hooks are affixed. There was a lacerated wound of the right cheek on a level with the angle of the mouth, and about two and a half inches from it. There was considerable contusion about the temple and the eyelids, the eye was bloodshot, and there was considerable chemosis.

It was on account of the eye that he applied for treatment.

He stated that immediately after the accident he had walked to the Chambers Street Hospital, where his injuries had been attended to. The wound in the cheek was apparently not a deep one, and had not penetrated into the mouth. It had been closed with sutures, but was now filled with pus. I removed the sutures and examined the wound, without discovering that it was more than superficial. I found some periostitis of the orbit and adjoining bone.

An ophthalmoscopic examination of the interior of the eye under atropine mydriasis, revealed an entirely normal fundus, and the patient's vision was, as in the other eye, normal.

Supposing that no serious injury had been inflicted, I ordered ice applications to the right side of the head, and directed the patient to return on Thursday.

He came, and it was at once plain that the character of his injury had not been appreciated, for then cerebral symptoms were well declared. I advised him to apply immediately for admission to the hospital. This, however, his wife declined, and begged me to attend him at his house.

When I saw him an hour later, I found that he had a temperature in the axilla of 102° F. He was somewhat stupid, though answered intelligently, complained of pain in his head, and was constipated.

I found, upon careful examination of the wound in the face, that a probe could be made to pass inward and upward, to the extent of three inches, without then seeming to reach the end of the canal. Exophthalmos, which had not been noted on Tuesday, was now marked.

An ice-bladder was ordered to that side of the head, and a croton-oil purge given.

Punctured fracture at the base of skull was diagnosed; an unfavorable prognosis was given the family, and a consultation was suggested to them. On the morning of the 20th all the symptoms were aggravated; temperature, 104° F.; patient more stupid, but when aroused answered properly, complained of great pain in right side of head; very little discharge from the wound in the face. The bowels had moved freely. The ice-bladder was continued, and at 12 o'clock Dr. L. Weber saw the patient in consultation. In the single previous explora-

tion of the tract of the wound, which I had made in the presence of Dr. Mundé, the probe had passed upward, backward, and inward, following the direction of a line drawn from the external wound to the inner side of the root of the nose. In the examination now made in conjunction with Dr. Weber, and first demonstrated by him, it was rendered apparent that the hook had passed further outward than I had supposed, and had penetrated the roof of the orbit toward its outer side, instead of through the ethmoid in the region of the sella turcica.

The consultant advised against any operation at the time, on account of the condition of the patient. The patient's temperature was 105° F., and his general condition was about as on the previous evening. There was no paralysis except of the vesical sphincter.

It was now observed that, though he ate such food as was given him, and drank with avidity, as indeed he did, up to within fifteen minutes of his death, he either could not or would not utter any word, and remained in possession of the full use of all his limbs, yet speechless, until 10 o'clock on Sunday morning, when he died. The patient's condition at my visit in the evening had remained the same, except that his temperature had gone up to 106° F., and between 9 and 11 o'clock on the night of the 20th he had a number of severe convulsions.

At about 12.30 on the morning of the 21st, with the assistance of Dr. Weber, Dr. Mundé, Dr. Saunders, and Dr. Holmes, the patient being etherized, I made an incision along the superior border of the right orbital fossa, extending from the nasal prominence of the frontal to about three-quarters of an inch beyond its external angular process, and down to the bone. I then dissected the orbital tissues away, keeping close to the bone, and dislocating the eyeball downward and inward. Continuing the dissection backward, I came upon the site of the fracture, about one and three-quarter inches from the upper orbital margin, and a little to the outer side. On reaching the place of the fracture, about a tablespoonful of very fetid, red-colored pus escaped, together with a quantity of gas. The patient's breathing, which had been for some time labored and rapid, immediately sunk to the normal, accompanied by a deep sigh. I desired to further enlarge the incisions, and remove any spicula of bone, which I was confident would be found pressing in the brain, but it was advised to do nothing further, but dress the wound and put in a drainage tube, which was accordingly done. The outer incision was closed with sutures to its external angle, where the tube was brought out, and the man put to bed.

An hour after the operation his temperature, which had been 106° F. immediately before, had fallen to 103½° F. The relief was, however, only temporary, and he had convulsions again before morning. When I saw him at about 11 A.M. I re-opened the wound, and evacuated a considerable quantity of pus, the drain-tube having become clogged. I then inserted a horse hair drain, and ordered ice to the part, together with supportive measures.

The patient died at 9 o'clock A.M., on Nov. 24th. At 5 P.M. of the same day, assisted by Drs. Holmes and Saunders, I made an examination of the interior of the skull. We found the hook had entered the cheek as indicated, had coursed upward and inward, passing behind the zygomatic process of the malar, through the sphenomaxillary fissure, fracturing the bones on either side, and through the roof of the orbit, about 1½ inches back and a little to the outer side, producing there a comminuted punctured

fracture, lacerating the dura mater, and forcing several plates of the thin bone into the substance of the brain.

An abscess had formed in the brain, having the form of a cone, its apex upward, and about 1½ inch deep by 1 inch at its base. Immediately around the abscess cavity there was a zone of intense cerebritis; there was intense congestion of the entire brain, and very plentiful deposits of pus in the meshes of the pia mater over its superior portion. The cavities of the arachnoid and the ventricles had not an unusual quantity of fluid in them.

The mortality in ordinary punctured fracture of the skull, where trephining is resorted to early, is always very large; yet an operation which shall have for its end a removal of any and all substances which are acting as a foreign body, must certainly always remain an imperative and unvarying rule of surgery. Had I appreciated the gravity or exact nature of the injury which the man had sustained when first I saw him it would then possibly have not been too late to have resorted to a radical operation for his relief. An examination of his face-wound was, however, as superficial and barren of real information as to his true condition as had evidently been the case with the surgeon who first saw him and closed the wound with sutures. The condition of the eye and adjacent parts was, when taken by itself, misleading. I have very often seen a similar picture presented as the result of slight injury or from an ordinary periorbitis without assignable cause, chemosis of the ocular and palpebral conjunctiva being constantly present, even with very slight periostitis, such as may accompany an hordeolum at the outer canthus. The ecchymosis in this case was not greater than would have been accounted for by the blow received by falling upon the temple, which involved the outer angle of the orbit, and though most marked in the upper lid, was not confined to it.

Lastly, the interior of the eye, examined after complete mydriasis, showed no lesion whatever, proving—though the globe must have suffered considerable compression, which, as the subsequent history developed, was kept up several minutes, the man remaining suspended upon the hook till lifted down—that such compression may leave no trace.

The probe, as first introduced by me, evidently left the track made by the hook and wandered into the adjacent cellular tissue.

It may be that the "centre for language" is not invariably in the *left* anterior lobe, but may sometimes develop in the corresponding part of the brain upon the *right* side. This man, though not suffering from paralysis of any of the muscles used in phonation, was manifestly unable to form words, though sounds he freely uttered which much resembled those used by the deaf and dumb. Perhaps his memory for words had been annihilated. If the hypothesis of a transposition of the centre for language to the right side be not too radical or violent, then the abscess and zone of cerebritis in the anterior lobe, and involving the island of Reil, would well account for the abolition of that faculty. The subject was right-handed.

113 E. 59TH STREET.

TRANSLATION INTO FRENCH.—Dr. Wm. A. Hammond's work on nervous diseases has been translated into the French Language by Dr. F. Labadie Lagrave, who has added chapters on more recent discoveries in neurological medicine and on cerebral syphilis.

ON THE USE OF OXALATE OF CERIUM IN PERTUSSIS.

BY BENJAMIN MORJÉ, M.D.,

PHYSICIAN TO THE GERMAN DISPENSARY, NEW YORK.

A MULTITUDE of opinions exist concerning the pathology of whooping-cough. It has at various times been called a variety of bronchitis, a specific neurotic disease; again, it was said to be due to an irritation of the pneumogastric nerves, in consequence of inflamed lymphatic glands. Some believe it to originate in a contagium taken up by the respiratory mucous membrane, which irritates the centre of the respiratory nerves in the medulla oblongata, giving rise to the convulsive paroxysms of cough. Lately it has been defined as a catarrh of certain portions of the respiratory tract, combined with the immigration of a fungus. From these situations, by irritation of the endings of the superior laryngeal nerve, the paroxysms of whooping-cough are said to be caused by reflex action. (Hagenbach.) This would make it seem that the infection is localized. Observers who have made the theory of infection the subject of special research emphasize that the micrococci occurring in whooping-cough differ from those of diphtheria, in not penetrating the epithelium and mucous membrane of the parts. (Letzerich, quoted by Hagenbach, in Gerhardt's *Handbuch der Kinderkrankheiten*.)

A corresponding mass of medicinal agents was the result of each innovation, so that, in the course of time, through the inefficiency of most of them, an apathy took possession of the profession, which led to the other extreme, in not giving any remedy to mitigate the suffering of the patients, thus permitting the disease to run its course, and trusting to its self-limitation.

Even Vogel at one time declared that there would never be a remedy to shorten the course of pertussis.

Niemeyer was more conservative, and thought that, if we were able to moderate the paroxysms of the cough, we could thereby shorten the career of the disease.

It is useless to enumerate the numberless remedies which have been in turn recommended for application locally, internally, and for inhalation and insufflation. Lately, quinia has been used by the adherents of the theory of infection, and was thought to be efficient by its local influence on the specific catarrh of the pharynx and upper laryngeal region. (Binz.)

It is immaterial from which pathological standpoint we consider the disease, so long as we concede to it a spasmodic stage—and the second stage is certainly one *par excellence*. Its importance is not to be overlooked when we consider that pneumonia is most often developed in it, and an antispasmodic agent is clearly indicated. I have found a very reliable one in oxalate of cerium, whose action as a nervous sedative was long ago established by Simpson in the vomiting of pregnancy.

In the May number of *THE MEDICAL RECORD* of last year, an article from the *Practitioner*, having Dr. Thomas Clark for its author, was quoted, in which he states that oxalate of cerium was by him used in chronic cough, with excellent results. To this was afterward also added the testimony of several physicians in this country who had found it reliable in the same ailment.

This encouraged me to try it in the spasmodic stage of whooping-cough, and with excellent results, often astonishing by the promptness of its action. Not only was the frequency of the attacks reduced, but

their intensity was also lessened in each case, giving the patient an excellent night's rest, and invariably shortening the second and most severe stage of the disease. No claim is made as to its action on the first or third stages; but the second, as it is by far the most harassing, naturally demands our greatest attention. I have thus far used it in ten cases, of which seven were females and three males. Two of the cases were complicated with other diseases. The mode in which the oxalate of cerium was administered was always the same, it being given in one single dose each day, and before breakfast. The ages of the patients under observation ranged from one to seven years, and the oxalate was administered in one-half grain to three-grain doses.

CASE I.—A girl aged seven years. After a preliminary bronchitis the characteristic whoop declared itself. Bromide of ammonium, belladonna, chloralhydrate, etc., were given, but seemed to exert little influence, when suddenly the cough ceased, only to give way to typhoid fever, which, with its relapses, lasted for six weeks. Hardly was the patient up again before the whooping-cough reappeared, with even more severity. Expectorants were given, and one dose of 2 grs. of oxalate of cerium half an hour before breakfast each morning. The salutary effect of the oxalate was quickly apparent; but, to see if its action was not overestimated, it was withdrawn for several mornings, when, instead of having light attacks of coughing once or twice a day, with nocturnal quietude, greater intensity and frequency of the attacks quickly ensued. The cerium was again resorted to, and the child soon recovered with but slight inconvenience.

CASE II.—Girl four years old. Had whooping-cough two weeks, when scarlet fever appeared in a very severe form, being complicated with abscesses, uræmic convulsions, etc. The pertussis did not at any time abate, but steadily increased in severity. Of course, with such a number of troubles, much attention could not be bestowed on the cough; but after convalescence as regarded the scarlatina had been established, the pertussis was treated. Oxalate of cerium was given as above, in one-grain doses, once a day before breakfast, with quick amelioration of the harassing cough. It may be here stated that, to reduce the high temperature of the scarlet fever, quinia was repeatedly given in large doses without having the least effect in counteracting the pertussis.

CASES III AND IV.—Boy nineteen months old and girl aged three years, attacked with whooping-cough; coughing spells frequent and severe, occurring once to three times each hour. Bromide of ammonium and belladonna were followed by no improvement, excepting easier expectoration. Epistaxis and frequent vomiting, accompanied by a cyanotic countenance, in both cases. The oxalate of cerium was given before breakfast, in one-half and one-grain doses respectively, once a day, with almost instant relief, the attacks being reduced to two or three light ones in twenty-four hours, instead of occurring hourly and with greater severity. To demonstrate the usefulness of the remedy it was withdrawn for several days, though the bromide and belladonna were continued, with the same result as in Case No. I.

The other remaining cases were uncomplicated ones, and yielded to the oxalate of cerium most satisfactorily, being relieved with the same promptness as the preceding ones. The rule was also observed in each case to continue the remedy one week longer than there was any existence of the whoop, to obviate the possibility of a relapse.

In conclusion, it is claimed for oxalate of cerium that:

1. It decreases the attacks, and thereby reduces the violence of the disease, often checking it instantly.
2. It is easily administered, as only one dose is required in twenty-four hours.
3. Nocturnal quietude is insured.
4. The possibility of complications is lessened.

In this city, as Dr. John C. Peters has shown in the *Record of May 21th*, pertussis is tending to epidemic frequency, and 219 deaths have occurred from it in the first quarter of 1879. For this reason, the evidence furnished by the limited number of ten cases was thought to be sufficient in urging a trial for oxalate of cerium.

Progress of Medical Science.

BLUE URINE.—M. A. Robin recently presented to the *Société de Biologie* several specimens of blue or green urine passed by patients suffering from different affections. Several years ago he submitted to the society a specimen of blue urine passed by a hysterical patient. This urine, when treated with bases, assumed a more intense blue color; when treated with acids, it became red. Since then he has met with nine cases of this anomaly: six of them were convalescents from typhoid fever; one was suffering from chronic myelitis; and two from hysteria. In 1823 Breconneau reported a case of blue urine, in which he claimed to have found a peculiar substance, which he called cyanurine. He did not, however, state what this cyanurine was. M. Robin distinguishes two kinds of blue urine: 1st, that which is blue spontaneously, and 2d, that which becomes blue as a result of ammoniacal fermentation. Of this second class he makes also two subdivisions: 1st, that which becomes blue only on the surface, the change being due to the presence of inferior organisms of a blue color; and 2d, that which is charged with indican.—*La Tribune Médicale*, March 30, 1879.

THE PLAGUE.—The following brief abstract of a lecture delivered by Professor Virchow, before the Medical Society of Berlin, contains the essence of the views held by that distinguished observer concerning the plague: He agrees with old observers regarding the swelling of the lymph glands, the so-called buboes, as the most striking feature in the disease. It is still an open question, however, whether or not these buboes constitute an essential factor of the disease; whether the so-called fulminating forms may not run their course without glandular swellings. The glands accessible to palpation are not the only ones involved; the entire lymphatics appertaining to the individual regional affections are progressively attacked. The characters of the glandular swellings are analogous to those of the gland-swellings in typhoid fever; they consist of cellular hyperplasia, with more or less hyperæmia and hemorrhagic effusions. The mode of ulceration, however, is perhaps different. In typhoid a small spot of central necrosis forms, and suppuration takes place around it, but within the limits of the gland; in the plague, on the contrary, according to the more trustworthy observers, the suppuration takes place around the gland. Professor Virchow is not disposed, however, to accept this statement unqualifiedly, although he possesses no facts on which to base

a contrary opinion. He believes that in the recent Russian outbreak the disease was the oriental, and not the Indian plague; the last outbreak of the latter took place in 1838.

Next in point of interest to the buboes are the carbuncles. These occur in about one-fifth of the cases. They are located on the surface of the extremities and on the breast, and present the closest resemblance to the carbuncles of anthrax. They commence as small, red swellings, which grow very rapidly, and extend to the deeper structures; a vesicle forms on the top of each swelling, and bursts, and an ulcer then develops, which destroys the tissues deeply. Professor Virchow has not met with any description which would lead him to admit the occurrence of carbuncles in the internal organs. The petechiæ are often accompanied by larger ecchymoses. These are met with in the internal organ as well as on the surface of the body; and, in fact, the internal hemorrhages seem to be more constant than the external. In the clinical histories of the oriental plague Professor Virchow has been struck by the great frequency of hemorrhagic affections of the urinary organs; hemorrhages from the lungs are much less frequently recorded. The splenic tumor is a very constant and important symptom. Swellings of the liver and kidneys have also been reported; they are probably due to acute parenchymatous changes.

Professor Virchow believes that the epidemic which raged in Kurdistan and Mesopotamia, and was declared by the Turkish surgeons to be petechial typhus, was really the plague. He draws attention to the fact that specific local affections, and more especially glandular affections, are exceedingly rare in typhus, of which the exanthem, the splenic tumor, and the parenchymatous swelling of the liver and kidneys, and sometimes of the cardiac muscle, constitute, as a rule, the sole lesions. When told that an epidemic of petechial typhus, with "metastasis bubonica," rages in any place (as in Salonica), he is disposed to believe that the disease is really the plague. With regard to prophylaxis, he believes in the efficacy of a strict water quarantine, and of isolation, by means of successive cordons of soldiers, of small, affected districts; but thinks the attempt to quarantine the entire Russo-German boundary impracticable. For the disinfection of garments, etc., he prefers dry heat, which he believes to be much more effective than sulphurous acid. He thinks that, of all diseases, anthrax presents the closest analogy to the plague.—*Berliner klin. Wochen.*, March 3d.

CIRRHOSIS OF THE LIVER COMPLICATED BY THROMBOSIS OF THE PORTAL VEIN.—A case of cirrhosis of the liver occurred in the service of M. Raynaud, at the *Lariboisière*, in which the following points of interest were noted: 1st. Total absence of the classical symptoms of cirrhosis ascites, and dilatation of the cutaneous abdominal veins, thus obscuring the diagnosis of the hepatic affection; 2d. The rare complication of thrombosis of the portal vein; 3d. The occurrence of hemorrhages into the stomach and intestines, which led to an error in the diagnosis; 4th. The absence of ascites, with the complete obstruction of the portal vein by a thrombosis which the anatomical lesions demonstrated to have existed for some time. It would seem, indeed, that the first effect of obstruction to the portal vein should be a more or less rapid collection of ascitic fluid, together with dilatation of the collateral veins; this, at least, is the result of most of the observations of this accident. From twenty-eight observations of obstructions of the

portal vein, Frerichs cites but three cases in which there was no ascites, but in these there were hemorrhages into the stomach or intestines, which this author believed to be supplemental to the ascites. In the present case, however, the intestinal hemorrhages could not be due to the thrombosis, for the hæmatemesis extended over a period of twenty months, and the thrombosis certainly occurred at a later period of the disease, after the occurrence of the first hemorrhage. The following explanation is therefore given of the symptoms presented: In the course of cirrhosis the patient is seized with hemorrhage from the stomach, caused by the interference with the portal circulation, and the tendency in hepatic disease toward multiple hemorrhages. In the later stages of the disease thrombosis occurred spontaneously, favored by the obstruction to, and consequent slowing of, the portal circulation; by the very marked anæmic condition of the patient, and by the tendency to coagulation of the blood of cachectic subjects. The absence of ascites after the portal obstruction can only be explained by the occurrence of abundant intestinal hemorrhages during the last few days, which acted as a derivative, and depleted the abdominal system.—*Le Progrès Médical*, March 8, 1879.

FATTY EMBOLISM OF THE LUNGS FOLLOWING FRACTURES.—M. Déjerine presented to the *Société Anatomique* the notes of two cases in which he observed fatty embolisms in the lungs after fractures. In the first case the lower part of the leg was crushed by a railway car; a longitudinal fracture of the tibia, extending upward into the knee-joint; death followed in two and a half hours. At the autopsy the lungs and heart were removed together and very carefully examined. The blood in the right ventricle contained a large quantity of fat in little drops, which dissolved in ether, and were colored black by osmic acid. The pulmonary vessels were gorged with fat, the arterioles, venous radicles, and capillaries containing masses three, four, and five millimetres in length, which refracted light strongly, disappeared under the influence of ether, and showed, after the action of osmic acid, a deep black color, which traced the vascular network almost completely at certain points. The examination of all parts of both lungs gave the same result. The second case was no less convincing than the preceding. It occurred in the service of Dr. Brouardel, of San-Antonio, and the lungs were examined in conjunction with M. Mayor. The patient died thirty-six hours after receiving a fracture of the right parietal bone, and, as in the former case, the pulmonary vessels contained fat, but in somewhat less quantity. In neither case were the other organs examined for fatty embolism.—*Le Progrès Médical*.

CHOLECYSTOTOMY.—Mr. Bryant presented the following case to the Clinical Society of London: A single woman, aged 53, was admitted into Guy's Hospital, under Mr. Bryant's care, in July, 1878, with two discharging sinuses of three years' standing, following an abscess which had been previously forming for two. At first the sinus was laid open and pus alone escaped, but subsequently, as bile flowed in quantities from the wound, an exploratory operation was performed, and at a depth of two inches a biliary calculus one inch long turned out of the gall-bladder. Everything went on well after the operation, and, although bile continued to escape from the wound for about two weeks, the parts were quite healed in about four months, and the patient left the hospital cured. The author brought the case before the society as an en-

couragement to surgeons to try their art in allied cases, for he was well prepared to support the suggestions of Dr. Thudichum, made twenty years ago, "that gall-stones might be removed from the gall-bladder through the abdominal walls;" and he pointed out that under certain circumstances the operation was justifiable, when the sinuses by their presence were setting up inflammatory and suppurative changes about the gall-bladder, without any obstruction to the bile duct, as well as in that more serious class of cases in which the cystic or common bile-duct was obstructed, and dropsy of the gall-bladder with jaundice complicated the case, as shown by the cases of Dr. Sims, and Mr. G. Brown.—*The Medical Press and Circular*, May 14, 1879.

SUTURAL JUNCTION OF THE ULNAR NERVE.—In reporting this case to the Clinical Society, Mr. Hulke said the procedure was a rare one, but where practised had already given most satisfactory results, and held out the promise of restoration to many an otherwise crippled limb. His case was interesting from the long interval (fifteen weeks) that elapsed after the injury before the operation was performed, and for the speedy restoration of commencing nerve function, which was only three or four weeks after the operation. The patient, a blacksmith, æt. 53, was struck by a slate from a roof in a hurricane, across the inner side and front of the elbow. The wound healed slowly, and was painful from the first, the pain assuming a neuralgic character. The forearm and arm wasted, the man's health suffered, and he was quite unable to do any work. Fifteen weeks afterward, all parts supplied by the ulnar nerve in the hand were numbed and cold, and the scar in front of the elbow was exquisitely tender. The patient was then chloroformed, and an Esmarch's bandage put on. The ulnar nerve was exposed at the elbow and found to be completely divided, and the two ends widely separated. The upper end was bulbously swollen and dragged out of its course by the shrinking scar; the lower end was shrivelled. In both ends were minute particles of slate embedded. Both ends were removed by clean transverse sections, and were then found to be three-quarters of an inch apart. In order to bring them together, the upper end was stretched and drawn down and joined as closely as possible to the lower one by four silk sutures passed through the sheath. Absolute contact was not attainable. The operation was done and the wound afterward dressed antiseptically. The neuralgia ceased at once, and did not recur, and in less than six weeks the patient returned home. Sensation, which had begun to return about a month after the operation, rapidly increased, so that, upon leaving the hospital, the man went at once to his work. In the discussion which followed, Mr. Hulke remarked that the ends of the nerve after the operation were not absolutely touching, but were as nearly as possible together without actual contact. Other cases, with a longer interval than his own between the injury and the operation, had been recorded. He had himself, in excising pieces of nerve for frontal tic, been sometimes quite annoyed at the rapidity and thoroughness with which nerves were repaired: in one instance, after excising nearly half an inch, sensation returned. In the present case Mr. Hulke thought he had removed three-quarters of an inch of the nerve at the time of the operation. As to the trophic condition of the skin, he could say nothing about it. The patient had long since left the hospital and was now at work.—*The Medical Press and Circular*, May 14, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

SCHOOL HYGIENE.

THE close of the school year and the commencement of the summer vacation suggest many topics connected with school management, past and prospective, which invite passing comment. In glancing over the past, and viewing what has been done in the way of perfecting our systems of public education, we have, as a young country, just reasons for pride. Whatever else may be said of frauds, in other departments, concerning the prostitution of the general welfare to political purposes, that of education has been more or less exempt. The desire has been in every part of the country to perfect the system, to keep it untrammelled of mere party influences, and raise it to the highest possible level of utility. So apparent, indeed, is this, that an inordinate zeal is manifested, and the true end of education is in danger of being lost sight of in the effort to teach beyond the capacity for learning. But this is an evil so well recognized by every calm thinker, be he lay or professional, that we hardly dare refer to it without an apology for so doing. Still, so long as there is a wrong, all efforts to right it are excusable, even to the point of reiterating old truths, using old arguments, or reciting threadbare tales.

It is encouraging, however, to think that the numerous discussions of the subject have not been in vain, that new ideas of education are beginning to prevail, that the cramming system is losing popularity with our best educators, and that the promise of a better future is brightening before us. This is more particularly true with regard to some of our private institutions, and notably with some of our leading colleges. The public schools, although they have made notable progress in this respect of late years, are still very much in the background in regard to the proper use of their privileges. The agreeable offset to the cramming system which prevails in these institu-

tions is the fact that the vacations are long and give good opportunities for recruiting.

The system of our public schools, at least those in this city, is founded apparently upon the principle of making the best show in the school examinations. With such an end in view, the teacher is necessarily stimulated to get over the most ground possible, and by dint of severe drilling to make the best exhibit of the results to the examining board. No one needs to be told that the scholars are not only damaged mentally and physically, but are really worse off, as far as learning is concerned, than if no efforts had been made to educate them. So long, however, as the trustees demand such a showing on the part of the teachers, so long will the latter crowd the capacities of their pupils to the utmost.

Coupled with this system are the unsanitary conditions which surround most of our public schools. This remark does not apply particularly to those of this city. All over the country complaints arise regarding this subject, and it is to the credit of the profession that it has spoken so plainly upon matters of school hygiene, and has used its influences so effectually in creating a proper public opinion.

While our schools in the city are situated for the most part in unhealthy localities, in tenement districts, and are surrounded by all the possible unsanitary conditions, our district schools over the country are, relatively speaking, no better favored. The country school-house is generally poorly built, of inferior capacity, with no provisions for ventilation, and situated in the most barren spot in the whole district. Added to these drawbacks is not unfrequently the positive unhealthfulness of the locality. Stagnant pools surround the building, the drainage is imperfect, and the only redeeming feature in the whole picture is that the reeking privy-vault is sometimes respectably distant from the house.

But we are not called upon to dwell upon what must be facts well appreciated by all, but to make their reiteration another excuse for what, whether from a purely mental, or from a more strictly physical point of view, we may legitimately style sanitary reform in school management. The opportunities to such an end are given school managers during the present vacation. During the summer absence of the minister the church is renovated and put in decent order, and why should not the school-room, occupied so many hours more by our children, share the same fate? There is enough to do in increasing the ventilation and improving the surroundings of all our schools, and particularly so in our own city. It seems almost like wasting words to urge these obvious duties on all concerned, but we are willing to risk our efforts as fruitless in the consciousness of speaking once more for the school child, who is loaded down with tasks, and who is wearied with long hours of study, poisoned by the foul air in the school-room,

and perhaps permanently ruined in health. We have faith, however, that eventually the public will be educated to the point of demanding these necessities, and we patiently bide the time.

THE TENEMENT-HOUSE ACT.

THE Board of Health has received the requisite appropriation for carrying out the provisions of the new tenement-house act, and have commenced a series of improvements which must eventually be of great benefit to those compelled to inhabit these structures.

The new law greatly enlarges the powers of this board in the supervision of proposed buildings for tenement-houses and the inspection of existing structures. For several months past the Board have required those proposing to erect tenement-houses in this city to submit to them the plans for approval, with special reference to light and ventilation. The new law so amends the old act that, hereafter, it shall not be lawful to erect for, or convert to, the purposes of a tenement or lodging-house, a building on any lot where there is a building on the same lot, unless there is a clear open space exclusively belonging thereto and extending upwards from the ground of a distance varying from ten to twenty-five feet, according to the height of the building.

At the rear of every such house there shall be a clear open space of not less than ten feet between it and the rear line of the lot, subject to modification by the Board of Health in special cases.

Another provision of the act is that no one continuous building for tenement-house purposes shall occupy more than sixty-five per centum of the said lot, and in the same proportion if the lot be greater or less in size than twenty-five by one hundred feet. This provision, however, does not apply to corner lots, and may also be modified in special cases by a permit from the Board of Health.

One of the sections of the new law provides for a thorough system of ventilation, and regulates the height from the floor to the ceiling, and the existence of windows connecting with the external air. The total area of window or windows in every room communicating with the external air shall be at least one-tenth of the superficial area of every such room, and the upper half shall be so made as to open the full width.

Provisions are also made for the ventilation of every room which does not communicate directly with the external air, and is without an open fire-place, by special means of separate air-shaft, extending to the roof or otherwise, as the Board of Health may prescribe.

By section 3 the Board is empowered, in cases of overcrowding, to issue an order requiring the number of inmates to be reduced within ten days.

This is a matter which has long been discussed by the health authorities, but the lack of proper provisions, in previous acts, has crippled their movements

to such an extent as to render their efforts at making the necessary reforms almost powerless.

Giving the Board of Health such absolute power in the matter of constructing buildings from a sanitary point of view, throws upon it a great responsibility. We have no doubt that they are prepared to meet it, and, as the appropriation has been made, that the money will be judiciously spent. Of course, considerable time must elapse before the necessary inspections are completed, but when this is done we shall probably have a report of the doings of the inspector which will give us more insight into construction of tenement-houses, and the manner in which their occupants live, than we have hitherto had. The original law contemplated the levying of a tax upon each owner of a tenement-house, but by some political manoeuvre this personal tax was transferred to the city treasury. Although it would be more equitable to have those persons who are directly benefited by the tenement-house system pay for necessary improvements, it nevertheless cannot be made a cause for grievous complaint. The appropriation is not excessive, as compared with others for which there is no benefit to the citizens at large. We are quite confident that, with the execution of the law left to the Board of Health, nothing will be omitted which favors its success.

YELLOW FEVER.

DURING the past week the country has been startled at the reappearance of yellow fever in Memphis, the city which suffered so severely from the epidemic last year.

At the present writing we are happy to be able to chronicle that it proved to be a superlative scare, for no new cases have developed within five days, and the prevailing impression with the health authorities of the city is that there is, at present, no further occasion for alarm. The National Board of Health was prompt in issuing recommendations which were designed to throw most effective barriers in the way of the spread of the disease from infected districts, and there has been a praiseworthy readiness on the part of exposed localities to comply with those suggestions. We hope the cordon of safety will be strongly drawn; that the desire to cheat conscience into a false security will not be manifest; and, that extraordinary homage to a political feature will not be seen. Frantic partisanship to law is usually just in proportion to the ignorance of its spirituality, and, when the spirituality is removed, the vengeance of the letter is sure to be felt. The letter and the true spirit will save the nation from the inroads of the destroying pestilence. The letter kills only when it is separated from the spirit, and of the separation the people alone are guilty. The union of the law and the hearts of the people who wish to secure the greatest good for the greatest number may save thousands of valuable human lives and millions of dollars' worth of property.

Reviews and Notices of Books.

THE ANATOMY OF THE JOINTS OF MAN. By HENRY MORRIS, M.A., M.B. Lond., F.R.C.S., Senior Assistant Surgeon to, and Lecturer on Anatomy and Demonstrator of Operative Surgery at the Middlesex Hospital, Philadelphia: Lindsay & Blakiston. 1879.

This book contains 450 pages, and is made up of a complete anatomical description of each of the joints in the human body. It is therefore a valuable book both for study and for reference. It supplies a want long felt, for, although we have numerous works on human anatomy in which the anatomy of the joints is given, it has been, to a very great extent, piecemeal, and the student has been unable to obtain a complete knowledge of the anatomy of any particular joint without being obliged to refer to separate portions of the same volume. In Dr. Morris's book can be found a complete anatomical description of each joint, embracing the ligaments, the synovial membrane, the bursae, the relations of the articular surfaces and the muscles, the nerves, the blood-vessels, and the movements permitted. The first two chapters are devoted to general remarks, a description of the various structures which enter into the construction of a joint, the varieties of joints, and the varieties of diarthrodial joints. With Chapter Three is commenced a description of the articulations of the skull which extends through Chapter Four. Part II. embraces four chapters, which contain descriptions of the joints of the spinal column, the lumbo-pelvic union, the pelvis, and the thorax. In Part III., containing seven chapters, the joints of the upper extremity are described; while Part IV., embracing five chapters, is consumed in describing the joints of the lower extremity. The old *pons asinorum* the Y ligament of the hip-joint, receives due inspection in this part, the author believing that "although the appearance may be produced by dissection, it does not naturally exist." The book is well illustrated, many of the plates being colored. In general accuracy and fulness it seems to be an addition to previous descriptions of some of the joints, and we are of the opinion that the author is entitled to credit for exhibiting a new method of stating what is already known. The copy which we have is poorly bound, and we hope is not a fair specimen of the work of these old and well-known medical publishers.

HAND-BOOK OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE THROAT AND NASAL CAVITIES. By CARL SEILER, M.D., Lecturer on Laryngoscopy at the University of Pennsylvania; Chief of the Throat Dispensary at the University Hospital; Curator of the Pathological Society, etc., etc. With thirty-five illustrations. Philadelphia: Henry C. Lea. 1879. 12mo. pp. 156.

This little volume is divided into fourteen chapters; the first five are devoted to the study of laryngoscopy and rhinoscopy, and the usual methods of local treatment by their aid. The remainder treat chiefly of the more common diseases of the throat and nasal passages, the final one consisting of a table of symptoms for differential diagnosis, similar to that of Mr. Browne, of London, in plan, but not exactly like it in execution.

The attempt to crowd so much into a small compass impairs the value of the work as a manual of diagnosis and treatment. Had its pages been made simply a manual of laryngoscopy and rhinoscopy, without any professions as a manual of therapeutics, it would

have better supplied a want long felt by medical students and others for concise, practical instructions in the manipulation of mirrors and instruments, especially since the edition of Mackenzie on the use of the laryngoscope has been out of print.

We can heartily commend the volume to the medical student as a good guide to the study of laryngoscopy and rhinoscopy, penned from the hand of a gentleman fully familiar with the subject of which he writes. The therapeutic portion will require supplementary study from other sources as the requirements of the practitioner gradually call for fuller information.

There are many good points in the volume, some of them evidently original. Of these we may specify a recommendation, in those rare cases where it becomes requisite to resort to a mechanical appliance to elevate a depressed epiglottis, to attach to the epiglottis a small artery forceps, such as is used for temporary compression, with a string and small weight attached to it; the denunciation of the use of brushes mounted in brass caps, and which are affected by the reagents used in applications to the larynx, etc.; the recommendation to burn off molten caustic from the end of a probe, after it has been used, so as to destroy all infectious material that might cling to it; the recommendation to frequently moisten a sponge with lime-water and the like, when employed in a respirator, to protect workmen from the vapors of acids; the use of a guarded pair of scissors for amputating an elongated uvula, an original form of which is illustrated; the application of a coating of nitrate of silver to the surface of an amputated tonsil to protect the wound from the influence of the air.

The chief criticisms we have to make are as follows:

The great advantage claimed for a head-rest in laryngoscopic manipulations is not generally acknowledged by laryngoscopists; a head-rest is, in fact, rarely used, and much more rarely requisite. The use of the stem of the rhinoscopic mirror to depress the tongue, as recommended by the author, has almost always been found by the writer to be more difficult and unsatisfactory than the use of a special tongue-depressor, be it nothing more than the forefinger, which, by the way, is sometimes the most satisfactory appliance for the purpose. In the figure representing the normal larynx in respiration, the thyroid cartilage is designated as the cricoid, and the cricoid as the first ring of the trachea; a repetition of the mistake made in Mackenzie's volume, from which the illustration has been taken. A mistake is made, too, in asserting that the well-known pyriform swelling over the supra-arytenoid cartilages, characteristic of laryngitis phthisica, is not mentioned in any of the books on the subject. The prevalence of post-nasal catarrh, as it is here termed, is evidently over-estimated.

The pathological portions of the book are concise, and in accordance with the advanced views of pathologists. The article on aphonia, and the allusions to voice throughout the text, are especially commendable as far as they go; and it is evident that had not the author been hampered by the effort to cover a great deal of subject-matter within limited space, he would have done himself a great deal of credit. Of the remaining subjects of disease, while we can only say that they are much more unsatisfactorily treated, for a similar reason it is to be stated that the principles of therapeutics inculcated are in the main judicious. Some recommendations of electric treatment and counter irritation are not usually resorted to, but experience in these particulars and in others differs very much with different observers.

In conclusion, we would express the belief that Dr. Sciler has given us a little guide that can be safely placed in the hands of medical students, to supplement the practical instruction in dispensaries and hospitals, and to assist the practitioner in familiarizing himself with the details of manipulation which he has not had the opportunity of observing personally. As such, it will no doubt reach a wide circulation, in the United States at least, and stimulate the author to more ambitious efforts.

DISEASES OF THE INTESTINES AND PERITONEUM. By JOHN DYER BRISTOWE, M.D., J. R. WARDELL, M.D., J. W. BEGGIE, M.D., S. O. HABERSON, M.D., T. B. CURLING, F.R.S., and W. H. RANSOM, M.D. New York: William Wood & Co. 1879.

This volume forms the fifth of Wood's Library of Standard Medical Authors. Most of the articles are from Reynolds's System of Medicine, the only exceptions being those articles on Diarrhœa, Diseases of the Duodenum, and Abdominal Tumors, which are from S. O. Habershon's work on "Diseases of the Abdomen." The reputation of the writers on these different diseases is so well known, and the articles themselves have been so highly spoken of, that any special notice of them is uncalled for. The volume is indispensable to those who are not fortunate enough to possess Reynolds's System of Medicine. We think that the publishers are to be congratulated on the wisdom of their selection, and are entitled to the thanks of the profession for thus placing within the reach of every one books on such practical subjects.

HOW TO TAKE CARE OF OUR EYES, with Advice to Parents and Teachers in Regard to the Management of the Eyes of Children. By HENRY C. ANGELL, M.D., Professor of Ophthalmology in Boston University, etc. Boston: Roberts Brothers. 1878.

This is a neat little book, in which considerable information about the care of the eyes is given in a compact and simple form. Some parts of it, we think, show evidences of carelessness in its preparation.

In the present state of knowledge, the facts regarding *weak sight* ought to have been stated more fully and more clearly than is done here. Some of the symptoms of asthenopia are given, and then follow some rules to be observed by those suffering from this trouble. The author then says (p. 17): "If the weak sight does not improve satisfactorily under the observance of the rules given, it will be necessary to resort to the use of convex glasses." Now, the symptoms of asthenopia which have been detailed may arise from several different conditions. It is true that the majority of weak-sighted readers of Dr. Angell's book will probably have hypermetropic eyes, and will probably need convex glasses; and yet it is quite possible that some of them will be weak-sighted from a very different cause, and, indeed, from a cause for which convex glasses would be just the wrong remedy. The author farther says, "for the benefit of such as are unable to get proper advice," that "the convex glasses will probably require to be of about 48-inch focus." It seems to us that this kind of prescribing is of questionable value, even for those whose asthenopia arises from hypermetropia. Of course, it might be quite erroneous for a different case.

On page 23 we read: "In over-sight one does not see with perfect clearness and ease at any distance. Very fine type like this [1 Jaeger], for instance, is not read even by those too young to be old-sighted, in a good light, quickly, fluently, and without effort." We infer that the author is speaking merely of the ordi-

nary testing of a patient for over-sight, and without the use of atropine. If this inference is correct, the passage quoted is untrue as to hundreds of cases of "over-sight"—even of the class which present annoying asthenopia. We think that the distinction between manifest and latent hypermetropia should have been fully stated, as it is a very important matter, and at the same time very easily understood.

The word *hypermetropia*, by the way, we have not found in the book. This seems to be an unfortunate omission, especially as the technical name for near-sight—*myopia*—is given.

A frontal headache is mentioned as one of the most common general symptoms of near-sight in school-children. We think that headache from hypermetropia is much more common, but we find no allusion to this in the book. We think it would have been appropriate, also, in a work of this kind, to have mentioned some of the interesting facts regarding other neuroses which seem to be connected with errors of refraction.

On page 22 we find: "In near-sight the eye-ball is too full or convex, and in over-sight it is too flat." This is a poor definition of the causes of these conditions. They are more correctly defined, however, in other places.

In explaining the causation of presbyopia, no mention is made of any failure of power in the ciliary muscle.

On page 16 is the following: "Never read when lying down: it is too fatiguing for the accommodative power." Other reasons why reading when lying down is so injurious should have been given.

Among the imperfections of the eye as an optical instrument, the author mentions "spherical aberration due to a lack of symmetry in the cornea and lens, or to a lack of correspondence in their axes. This makes the refractive power of the two inharmonious, creating a slight astigmatism." This is rather obscure, if it is intended to explain the natural astigmatism common to all eyes. Usually there is an astigmatism of the cornea, and of the lens, and one tends to neutralize the other.

As directions are given regarding the management of inflammations of the eyes, we think it would have been well to have mentioned some of the very common applications which ought *not* to be used,—such, for instance, as poultices. Having alluded to sympathetic ophthalmia, the remarks upon it might well have been a little fuller, as the disease is so important, and such sad results are constantly seen because laymen do not know more about it.

CHEMISTRY: GENERAL, MEDICAL, AND PHARMACEUTICAL, INCLUDING THE CHEMISTRY OF THE UNITED STATES PHARMACOPEIA. By JOHN ATTFIELD, M.A., and Ph.D., of the University of Tübingen.

ATTFIELD'S Chemistry has been so long before the profession, that there are few interested in the subject who are not familiar with it.

It is in the fullest sense of the word practical, and as such a valuable aid in the laboratory. Nevertheless, it does not fail to inculcate and explain the general principles of chemical philosophy.

The department of organic chemistry is very full in all that interests the medical and pharmaceutical student.

The artificial as well as the natural alkaloids are studied and their production explained, and in the end of the book is an appendix giving a table of official tests for impurities in pharmaceutical preparations.

The portions of the work of special interest to the practitioner are those devoted to toxicology and the examination of morbid urine and calculi.

The student of practical chemistry who has not the advantages of laboratory instruction, will find a valuable guide to his work in the volume before us, as the details are made so plain as to allow him to follow the author as an instructor.

AIDS TO FAMILY GOVERNMENT, according to FROEBEL. By PERTHA MEYER. Translated from the Second German Edition by M. L. HOLBROOK, M.D. To which is added an Essay on the Rights of Children and the True Principles of Family Government. By HERBERT SPENCER. New York: M. L. Holbrook & Co. 1879. 8vo, pp. 208.

It is a popular and perhaps natural custom to scoff at books as helps in treating so wayward a portion of humanity as children. We do not believe, however, that any one can read the present work without being impressed with its value. This value is due not so much to the practical hints given, as to the fact that there is throughout the book an undercurrent of earnest purpose to impress the reader with the importance of rightly educating the child, and of the immense difference which a proper and improper training can make in his future character and career. There are hereditary traits which no amount of education or force of environment can entirely eradicate; but, if it is possible to do anything in the way of modification or improvement, childhood is the time. Books which inculcate the importance of this deserve, therefore, both attention and encouragement.

EPITOME OF SKIN DISEASES, with Formulae. By TILBURY FOX and T. C. FOX. Second American Edition. Phila.: H. C. Lea. 1879. 8vo, pp. 216.

This edition has been enlarged to three times its original amount, and two-thirds of it is newly written. Its contents are admirably arranged, the symptomatology, pathology, classification, etiology, etc., being first treated of in a general way, and then the particular diseases taken up in alphabetical order. The names of the authors are sufficient indorsement of the reliability of the work, and in the narrow range to which epitomized works are confined this deserves a high place.

The classification of skin diseases adopted by the American Dermatological Society has been inserted.

NINTH ANNUAL REPORT OF THE NEW YORK OPHTHALMIC AND AURAL INSTITUTE for the year 1878.

This Institution comprises a dispensary and a hospital. In the former there were treated during the past year 4,084 cases for diseases of the eye, and 894 cases for diseases of the ear. In the hospital 394 cases were treated, and so many of these were pay-patients that the institution is to a large extent self-supporting. There were 355 important operations on the eye, and the success in these seems to have been extraordinary. Out of 60 operations for primary cataract 54 were successful. In 63 operations on the iris there were no failures; nor are there any recorded as resulting from the remaining 232 operations.

The School of Ophthalmology and Otology connected with the Institution consists of four professors, by whom four lectures a week are delivered, besides clinics. It is stated that the plan of instruction adopted is not surpassed by any other institution either here or in Europe.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 15, 1879.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

The Academy was called to order at 8.10 P.M. The minutes of the previous meeting were read and approved.

The Chairman of the Committee on Necrology, Dr. F. V. White, announced the death of Dr. H. S. Downs, one of the original members of the Academy.

SELF-LIMITATION IN CASES OF PHTHISIS.

DR. AUSTIN FLINT read a suggestive and interesting paper upon the above subject. It was more than forty years since Jacob Bigelow applied the term "self-limited" to certain diseases, and gave to it the following definition: "By a 'self-limited' (disease) I mean one which receives limits from its own nature, and not from foreign influences, which, after obtaining a foothold in the system, cannot, in the present state of our knowledge, be eradicated or abridged by art, but to which there is due a succession of processes to be completed after a certain time; which processes and time may vary with the constitution of the patient, and may tend to recovery or to death, but are not known to be shortened or greatly changed by medical treatment."

Since the publication of that discourse a host of diseases had been shown to be self-limited, but especially the essential fevers, inclusive of acute pneumonia, and many acute inflammations. By observations made in 1863, Dr. Flint proved that acute articular rheumatism, and also in 1873, that acute dysentery, belonged to that category.

It was interesting to inquire, in different diseases and in different cases of the same disease, how far the course and termination might be due to self-limitation. The object of the paper was to inquire how far the favorable course and ending of pneumonic phthisis were determined by self-limitation. So long ago as 1858, he published a paper in the *American Journal of Medical Sciences* in which it was claimed that pulmonary phthisis might be self-limited, and an analysis was given of twenty-four cases which had terminated in recovery.

That claim had been renewed in 1863, in a paper that appeared in the published Transactions of the New York Academy of Medicine, and it had since been reiterated in his work upon the Practice of Medicine, and more recently in his work upon Phthisis. Of all diseases, phthisis was the least expected to end favorably from intrinsic tendency. The cessation of its progress was considered as implying some extrinsic agency by means of which it had been arrested.

THINGS NECESSARY TO BE ESTABLISHED.

Dr. Flint inquired, What was necessary to establish the fact of a favorable course, and to prove of any other disease that its favorable course and termination were due to self-limitation? A disease belonged in that class when it ended in recovery independent of hygienic or therapeutics; in other words, when the favorable course and termination were due to intrinsic tendency, even though they were promoted by judicious treatment. On the other hand, a favorable intrinsic tendency might be obstructed by injudicious treatment.

Self-limitation could not be inferred from a single case, or a few cases, because the course and termination of disease might be affected by influences which were extrinsic, but not apparent. The cases observed, therefore, must be large. They must be carefully and honestly observed. There must be no room for doubt with regard to the accuracy of diagnosis. At once the difficulties became obvious which prevented the requisite study and observation, and the cases in which the requisite conditions were fulfilled were rare. But during a period of thirty-four years Dr. Flint had observed the histories of a number which he believed to be amply sufficient to establish the statement that

IN CERTAIN CASES PNEUMONIC PHTHISIS, OR PULMONARY CONSUMPTION, CEASED TO BE PROGRESSIVE AND MIGHT END IN RECOVERY FROM SELF-LIMITATION.

He had not included acute tuberculosis under that head, and had also excluded the disease known as interstitial pneumonia or fibroid phthisis. He should consider the term pneumonic phthisis as applicable to all cases of phthisical disease exclusive of acute tuberculosis and interstitial pneumonia.

Of 670 cases of phthisis, the list embracing a few cases of acute tuberculosis and interstitial pneumonia, 44 ended in recovery. In 31 cases the disease ceased to progress, remained non-progressive for several months, and in a majority of the cases for many years. In 31 cases the phthisical disease might be considered as having ended, complete recovery not taking place. Those 31 cases he regarded as hardly less valuable in the study than those which terminated in recovery. In 75 cases, therefore, there was either recovery from phthisis or the disease ceased to progress.

Such a collection of cases offered a rich field with reference to several points of inquiry; but only one was taken up, namely, the proof of self-limitation.

In how many of the cases was it evident from the history that the cessation of the disease was not due and its progress not arrested by medicinal or hygienic treatment? Answer to that question furnished proof of self-limitation.

MEDICINAL TREATMENT.

Of the 44 cases which ended in recovery, there were 23 in which there was no medicinal treatment to which arrest of the disease could be attributed. In the remainder of the cases medicinal treatment consisted in the use of simple tonics, but in none of them could the treatment be considered curative.

Of the 31 cases in which the disease was non-progressive without recovery, there were 15 in which there was no medication by which the disease was controlled, and in several none whatever.

In the two groups of cases, namely, those ending in recovery and those in which the disease was non-progressive, medicinal treatment was absent in about equal proportion; in the first group, 23 of 44; and in the second group, 15 of 31.

HYGIENIC TREATMENT.

In a considerable proportion of cases change in climate and other hygienic measures were not of such a character that potential influence could be attributed thereto.

Dr. Flint then referred to cases already published in his work on Phthisis, the histories of which he claimed established self-limitation in cases of phthisis.

He was unable to quote any authors who declared in distinct terms that phthisis was a self-limited dis-

ease. The curability of phthisis, however, was by no means a novel doctrine. All observers of much experience agreed that patients had recovered from pulmonary phthisis even after the formation of cavities, but in all those instances the disease had been supposed to be cured sometimes by medicinal, sometimes by hygienic treatment, or by both combined. The position had not been taken by others that the recovery was spontaneous in some of those instances.

Dr. Flint's first object was to show that he had been warranted by facts in taking the position that self-limitation, in cases of phthisis, was established.

His second object was to speak of self-limitation as bearing upon conclusions drawn with respect to the treatment of phthisis. If the disease ended in recovery, exclusively from intrinsic tendency, it was evident that self-limitation must be more or less concerned in cases in which recovery took place under different measures of treatment; that it was a factor co-working with certain measures. When that factor was feeble or wanting, curative treatment would not probably be of much avail. Allowance must be made for that factor in estimating the value of curative treatment. The extent of its working must be different in different cases; sometimes considerable, sometimes moderate, and sometimes slight. Recovery from phthisis, in order to become proof of the success of any method of treatment, must take place in a number of instances, so large as to render it certain that the real agency could not have been self-limitation. It would be unjust to say that therapeutics were powerless, because when combined with self-limitation they would probably save many cases which would not otherwise recover.

CHANGE OF CLIMATE.

Dr. Flint regarded change of climate as a most important measure in the early stage of the disease. With reference to the part of the world best suited for consumptive patients, experience was discrepant. He then referred to two patients who visited Nice; one was loud in praise of that locality for consumptives, and the other was equally energetic in disparagement of Nice. Self-limitation in one was effective, in the other it was wanting. The only truly scientific plan of investigation respecting changes of climate was to study results in a considerable number of cases. Dr. Flint then made an analysis of 74 cases in which temporary change of climate was an important, and in some the chief measure of treatment. Of the 74 cases, 9 ended in recovery, and in 13 the disease was non-progressive. 22 out of 74 cases were regarded as a number sufficiently large to warrant the conclusion that more or less curative influence was due to climate. To those were added other cases in which the disease was slowly progressive, and in only 11 of the 74 cases did it appear that there was no improvement following change of climate.

One of the most striking recoveries took place in New York City, and without any important medication.

The inquiry with regard to the best place for consumptives was important, but for lack of time it was essentially waived with the remark that the selection of the resort must be governed by the circumstances proper to each case. The same remark was applicable to other hygienic measures. An important point in the clinical study of phthisis, with reference to effect produced by change of climate and hygienic measures, was to make a correct estimate of the influence of self-limitation in determining a favorable course of the disease.

Third. Dr. Flint offered some remarks with regard to symptoms and signs by means of which judgment must be formed with reference to the influence of self-limitation in individual cases of phthisis. Was it possible to judge whether there was an intrinsic tendency to a favorable course and termination? The symptoms which warranted hope, sometimes even an expectation of a favorable course and termination, related especially to the circulation, to body heat, to alimentation, and to nutrition. Persistent frequency of pulse, fever, anorexia, and progressive emaciation, opposed reliance on self-limitation. In proportion as phthisis was well tolerated, there was room for hoping that the disease would prove self-limited. If tolerance was limited, self-limitation was proportionately weak or wanting. There were abortive cases of phthisis as well as of other diseases, evidenced by phthisical lesions found at the apex of a lung post-mortem, without clinical history. Self-limitation might be exemplified, notwithstanding a large area of consolidation followed by cavities of considerable size. Confinement of the affection within circumscribed limits, that is, an absence of signs indicating progressive extension and general diffusion, were the most reliable points for a favorable prognosis. Heredity was not incompatible with an intrinsic tendency to recovery, and reference was made to an illustrative case in which both parents, three sisters, and three brothers died of phthisis.

In conclusion, Dr. Flint remarked that his histories afforded proof that profuse and repeatedly occurring hæmoptysis, chronic laryngitis, pleurisy with effusion, and perineal fistula, were not by any means in all cases unfavorable with regard to prognosis based upon self-limitation.

The paper being before the Academy for discussion,

DR. W. H. THOMSON remarked that he was not certain whether Dr. Flint used the word self-limitation in the sense of spontaneous recovery, or whether he gave to it some of the definitions which would more clearly define the term.

He thought it proper to say of typhus fever that it was a self-limited disease; also, that small-pox and all the specific communicable diseases were self-limited, because they depended upon the introduction into the system of some morbid agent, which had more or less the property of reproduction. So, also, the term might include processes of repair, as after a fracture of a bone. Was it to be understood that the disease known as phthisis was regarded by the author of the paper as self-limited in the sense of having a definite series of processes in succession, and that such succession of processes, occupying a more or less definite period of time, had a tendency to end in recovery like a case of fever or fracture of the femur? If so, he could hardly at the present time accept the conclusion. If, on the other hand, it was understood that there was a tendency to spontaneous recovery, and that cases after such recovery could be observed, he fully agreed with the author, and notably on the view of the question of change of climate, regarding change of climate as beneficial. Change of climate was unquestionably beneficial, but not positively remedial. In order to be a positively remedial agent, the atmosphere of the supposed beneficial locality must contain ingredients which acted curatively. In the exceptional cases in which the locality was abundantly supplied with pine trees, that was perhaps true, but he thought that in the great majority of instances the tendency to recovery, induced by change of climate, resided either in the fact

that certain irritants were absent, or the possibility upon the part of the patient to take advantage of certain elements, such as being in the open air, and therefore avoiding what elsewhere was irritant. The system recovered spontaneously under the beneficial processes aided by change of climate, and with such an understanding he could accept the doctrine that phthisis was a self-limited disease.

His own feeling was that a reliance upon self-limitation in phthisis in the sense of self-limitation of the reparative processes of a fracture or a specific fever, would be rather mistaken and somewhat mischievous. He thought that a study of the causes which kept up prolonged inflammation of the lung might lead to a more proper appreciation of the reasons why it was so commonly a fatal disease. For example, he doubted if the tendency to self-limitation was sufficiently strong to heal even a simple wound, in case such wound was rubbed from eighteen to twenty-four times each minute, and yet such was the irritation to which an ulcerated lung was constantly subjected, thereby preventing that one thing which made any abscess a source of great danger—namely, prevention of the formation of a limiting membrane.

Again, the pus, through decomposition, was turned into a cauterant substance, and wherever it went it left its mark along the trachea and larynx.

Those were some of the reasons why the disease was not self-limited in the proper sense of the term.

DR. FLINT remarked that he did take the position that in certain cases of pneumonic phthisis there was a tendency to spontaneous recovery; that recovery took place in certain cases irrespective of any appreciable cause; that it was self-limited in the sense that typhus fever was self-limited, differing from it in certain respects, such as that in the latter the fever ran a certain course with regard to time, etc. He did assume that in both, in the pneumonic phthisis as well as in the fever, facts went to show that in a certain proportion of cases recovery was due entirely to self-limitation.

He did not wish it to be inferred from that view that we were to rely upon self-limitation. He did not take that ground, for the fact of self-limitation was consistent with the efficacy of medicinal and hygienic means. His object in bringing out the paper was to show that we had a factor the influence of which had not heretofore been recognized, and that we should ascertain how much allowance must be made for it when studying the effect of medicinal and hygienic measures.

DR. J. R. LEAMING remarked that if it was true the tendency of nature was to limit disease, according to the old doctrine *vis medicatrix nature*, the office of the physician should be to assist nature; but if he should go along with her, carrying a bag of pills, he might assist in not limiting the disease. According to Dr. Flint we must look to the mixed form of phthisis, that in which there was inflammatory action resulting in tuberculosis, for evidence of self-limitation. In that case Dr. Leaming thought it to be the *duty* of the physician to assist nature in limiting the disease. As he thought, the beginning of many cases of phthisis was in pleurisy, especially in subjects possessing tubercular tendency; and if that was true, the removal of the exciting cause—the breaking up of the pleuritic adhesions—was giving nature the best possible chance to effect a recovery. The best possible method of effecting that was by keeping the lungs full and free. If expansion of the chest was kept up, and the lungs kept free, the conditions of irritation were removed, and a tendency to tuberculous deposit

thereby relieved. Tuberculous conditions generally resulted from local irritations giving rise to hyperæmia. He had no doubt there were cases of spontaneous recovery from phthisis, but the factors causing that recovery were not so obvious. Changes in the seasons were sometimes attended by favorable changes in the progress of a case of phthisis, and a phthisis beginning in the winter might be entirely relieved by the coming of spring and summer weather. Nutrition also had very much to do with permanent improvement in phthisis. Sometimes nutrition became improved by accident not known, or change of diet not suggested by the physician. If the meaning of the appellation self-limitation was not such as obtained in typhus fever or in the exanthematous diseases, or those diseases usually called self-limited, he was hardly able to understand its application.

Dr. J. C. PETERS thought that some of the later views entertained regarding pulmonary consumption might throw light upon the subject under discussion. He was early taught that consumption began in the apices of the lungs; that for the time being the phthisical affection might cease until a fresh crop of tubercles was added lower down in the pulmonary tissue; that a succession of tuberculous deposits occurred, until large portions of one or both lungs became involved. If that doctrine was true, it was easy to understand how a cessation of the disease might occur. But lately he had studied an article in which the author took the position that the largest number of cases of phthisis recovered temporarily at least, and the view was based somewhat upon the doctrine stated above. It was known that after the first deposits of tubercle took place, inflammatory processes were usually established about them—in many cases they were not, and then the tubercles were frequently absorbed—and then it depended upon the condition of the patient's general health or the influence of some special cause, whether another tuberculous deposit took place. All physicians saw cases of recovery from consumption, and yet there were many others which he did not know how to control.

Dr. THOMSON regarded the question as an important one, and thought it should be discussed in a way which might perhaps sound rather singular for him to suggest—namely, why was phthisis not self-limited? If it was self-limited and had a tendency to recovery, then there must be many cases in which that element of self-limitation was interfered with, and such limitation was prevented. If it was a self-limited disease it was very important to fully agree with Dr. Flint, in order that we might not be misled and attribute recovery to other causes. Exactly what his views were upon the subject he was not at present able to say; for the subject was a large and important one, and demanded careful study. He had always understood self-limitation in disease as a term restricted to those which had a definite course, and running that definite course through a definite series of developments, and finally, after that definite course had terminated, ending in recovery. To include phthisis in that category because of certain cases which got well, cases which constituted a very small minority, was a view he was not prepared to accept. He was not prepared to admit as proven, that phthisis came under what he had understood by the term self-limitation. Nevertheless, if it was true that phthisis had a tendency of its own to recovery, or the reason why patients suffering from it did not get well was because foreign influences, foreign to its own tendency, interfered with it, it was an exceedingly important question for discussion.

Dr. FLINT, in explanation, remarked that he inferred from Dr. Thomson's remarks that he (Dr. F.) took the ground that phthisis, as a rule, had a tendency to recovery,—a position which he had not taken. The position which he took was, that there were certain cases which exemplified a tendency to recovery. The term self-limitation had been used somewhat loosely, but he had defined it as representing an intrinsic tendency to recovery, and in the light of that view he had studied the subject. Undoubtedly an intrinsic tendency to a fatal result existed in certain cases, whereas in other cases there was an equally undoubted intrinsic tendency to recovery. He did not wish to have the drift of the paper construed into an antagonism to means to be used for effecting a cure, but it was desirable to recognize the existence of the factor self-limitation, in order to determine, if possible, how far it was clinically operative.

The Academy then adopted the following amendment to its Constitution:

COMPOUNDING OF ANNUAL DUES.

"Any Fellow in regular standing who has attained the age of thirty years, and who has paid *five* annual dues, may compound for all future annual dues by the payment of \$150; one who has attained the age of thirty-five years, by the payment of \$145; one who has attained the age of forty years, by the payment of \$135; of forty-five years, \$125; of fifty years, \$115; of fifty-five years, \$105; of sixty years, \$95; of sixty-five years, \$80; of seventy years, \$65."

The Academy then adjourned, to meet at the call of the President.

Correspondence.

PERINEAL ARTIFICIAL ANUS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I read with much interest the recent report in the RECORD, of the highly interesting and pre-eminently fit proceedings of the Medical Society of Kentucky, in relation to the late heroic Dr. McDowell, of Danville, Ky., as well as the suitable remarks in a subsequent number of the RECORD in relation to the late Dr. Miller, of Louisville, Ky. Permit me now, through the same widely circulated medium, to call the attention of the medical profession to the just claims to their lasting remembrance and gratitude, of another long forgotten, but nevertheless worthy Kentucky pioneer surgeon. I allude to the late Dr. John P. Campbell, of Flemingsburg, Ky., who, on the 24th of November, 1800, performed the operation for *Perineal Artificial Anus*, in the case of a female infant three days old, having a congenital imperforation of the anus and rectum (*Atresia Ani et Intestini Recti*), being the first operation of the kind ever performed in the United States for this formidable species of congenital malformation. The operation, as will be shown, proved a complete success.

It will be observed that in this particular species of congenital imperfection no anus exists, and there is, generally, not even the trace of an anus to be seen *in situ naturali*, the perineal raphe being extended from the scrotum to the point of the coccyx without any interruption; and, should a considerable portion of the rectum be deficient, then, indeed, the case becomes most serious and embarrassing to the surgeon, as there is no external sign by which he can ascertain positively

where the end of the rectum can be found, or, indeed, whether the organ even exists at all or not. And to add still further to the difficulty and the perplexity, the rectum, besides being abnormal, sometimes occupies an abnormal position.

It was just in such cases as we are here considering that the celebrated French surgeons, MM. Amussat, Roux de Brignoles, and Goyrand, in their various publications on this subject during the years 1834 and 1835, declared that previous to that time such cases were never successfully treated, if treated at all, but were suffered to perish, because, as they imagined, their predecessors had not sufficient skill and courage to make free incisions in the perinæum, in order to search for and to find the blind end of the rectum when it laid deep. They claimed great merit to themselves for introducing, as something entirely new in such cases, free incisions with a scalpel, guided by the finger, instead of the old method of punctures with the lancet or the trocar. These distinguished surgeons were, however, anticipated by Mr. Benjamin Bell, of Edinburgh, who, half a century before, described most graphically this very operation in such cases of free incisions with the scalpel, guided by the finger, and who reports two interesting cases upon whom he himself successfully operated. (*A System of Surgery*, vol. ii., p. 277. Edinburgh, 1787.) They were also anticipated by Dr. Campbell, of our own country, in 1800. Such a grave case, in the subject of an unfortunate child, was suddenly thrown upon the charge of Dr. Campbell, in the then infant state of surgery in our country, and in the wild woods, as it were, of the infant State of Kentucky. How the doctor executed the difficult and delicate operation will be given in his own language in the following letter to Dr. Samuel Brown, of Lexington, Ky., dated at Flemingsburg, Ky., March 9, 1801, being upward of three months after the operation. This letter was subsequently published in the "Medical Repository" of New York, the oldest and most prominent medical journal then in the United States:

"November 23, 1800, I was called to visit the child of Mr. Hutson, in the vicinity of this place, on the second day after the birth. The case was an imperforate anus. As an operation was inevitable, the next day was determined upon for that purpose. On the third day, when I went to operate, the child was very fretful and uneasy, the abdomen was much distended and discolored, and, from the information of the nurse, the feces had been frequently vomited up through the day. I began the operation by making a longitudinal incision on the place where the anus should have been, which was slightly marked by nature. This incision I extended in the direction of the os sacrum with a lancet, until that instrument could be no longer serviceable, and no feces following it when withdrawn, I introduced the scalpel and carried it up in the same direction until I had the pleasing sensation of having reached a cavity. The instrument was withdrawn and the meconium flowed plentifully. The child was placed in a warm bath up to the middle for a few minutes, and after this a tallow bougie being introduced to keep the orifice open, the little sufferer dropped into a pleasant sleep. The bougie and warm bath were continued but a few days, with the occasional use of some magnesia alba and rhubarb, till the child recovered, and every expectation to be derived from the operation was fully answered. At this time the child does well, and the mother assures me that she observes nothing in its present condition different from that of others which she has already nursed. My only fear was that the

sphincter muscle might be destroyed, but I am now convinced no inconvenience will ever result from that quarter. It was a female child, and the length of the canula, which I ascertained by measuring the instrument, appeared to be about three inches."—*The Medical Repository*, vol. v., p. 45. New York, 1802.

In conclusion, I would remark that the late Dr. Campbell richly deserves honorable mention in the American history of surgery, for his genius, his courage, and his skill.

I am, very respectfully yours,

W. BODENHAMER.

249 MADISON AVENUE, NEW YORK, June 19, 1879.

CHRYSOPIANIC ACID—ITS USE IN THE TREATMENT OF SKIN DISEASES.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The following is a resumé of a series of articles published in the "Wiener Medizinische Presse," from April to October, 1878, by Prof. Neumann, upon the use of chrysophanic acid in skin diseases. Goa-powder is the product of a tree growing in the tropics of the Old and New World. It is the chief source (containing 84 per cent.) of chrysophanic acid. The action of this acid upon the skin is that of an irritant and a dye. It colors the linen and hair. The inflammation of the skin which it causes is often quite intense, accompanied by œdema, acne, and occasionally by chills. All these unpleasant symptoms disappear in about ten days. Prof. N. reports 26 cases of psoriasis: the age of the oldest patient 77 years, the youngest 16 months; longest duration of disease, 40 years, shortest six weeks; longest period of treatment, 16 days, shortest, three, which he has treated by the use of this remedy. In two of these the disease reappeared. He also reports 12 cases of chloasma uterinum successfully treated. He has also found it curative in pityriasis versicolor, herpes tonsurans, lupus maculosus and erythematosus, syphilis cutanea, maculosa and papulosa, vegetans, psoriasis syphilitica, palmaris and plantaris. Its use is contra-indicated in eczema (excepting eczema marginatum) and sycosis. He does not recommend its use in solution, but in the following ointment:

R. Ung. simpl. 40.00.
Liquefact. admisce exactissime,
Acid. chrysophan. 10.00
Adde Ol. bergamont. gtt. decem.

In psoriasis the treatment should begin with a warm bath, when the scales should be removed by means of a brush and *sapo viridis*. Baths are not advisable afterward, because in this way the ointment is brought in contact with the healthy skin. When extensively diffused upon the face and scalp, care must be used on account of the violent inflammation excited. The same remark applies to genitalia. Better results are sometimes seen by combining it with the tar treatment. In parasitic skin disorders an ointment in the proportion of 1 : 8 does best. In chloasma uterinum, lupus vulgaris, maculosus and tuberculosus, apply twice a day; spread on linen held in place by adhesive strips. Thymol should be added to the ointment for lupus erythematodes. It requires long treatment. While it does not prevent the reappearance of psoriasis, it removes it so speedily that in his opinion it may be regarded as one of the most important remedies in skin diseases introduced to the profession in the last ten years.

M. STANTON, M.D.

SYRACUSE, June 11, 1879.

QUACKS AND REGULARS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The RECORD of May 10th reports Prof. Edmund Andrews's paper on the treatment of hemorrhoids by injection. The doctor speaks of having corresponded "with a large number of itinerant doctors—many of them the *veriest quacks*"—on this subject, and has obtained statistics of numerous cases.

The paper describes the treatment—which I will not recapitulate—to have been very successful in the vast majority of cases, and endeavors to prove that we are indebted to *quacks* for *valuable scientific information*.

I desire merely to ask if it is customary for "*regular*" practitioners to compile their statistics of cases from the records of *quacks*?

Yours truly,

SOLON B. STONE, U. S. Army.

FORT BOWER, A. T., June 9, 1879.

Of course we do, Mr. Editor, whenever the quacks present any truths worth studying. We know that some of the brightest discoveries in medicine were made by empirics, and it is our glory that we seize on them and appropriate them to the benefit of mankind.

There was a body of quacks possessing a new treatment for hemorrhoids. They acquired an enormous reputation, and made their plan sweep the country with all the power of a great popular movement. They made tens of thousands of experiments with such éclat and success, that in whole regions they almost monopolized the treatment of piles. I saw that this immense mass of experiment was too valuable to be lost, and determined to collect the facts, sift the results, and put the whole on record for the study of the profession. Truth is immaculate, no matter whence obtained.

EDMUND ANDREWS, M.D.

No. 6 SIXTEENTH STREET, CHICAGO.

PUERPERAL HEMORRHAGE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I was called on the 1st day of April last to see Mrs. P., a delicate lady of forty-three years. I found her entirely prostrated from ante-partum hemorrhage. She is a multipara, and was then in her seventh month of pregnancy. By vaginal examination I found the os slightly dilated, but rigid. I ordered 30 gtt. of tinct. opii and 10 gtt. acid. sulph. arom. to be given every three hours. On the evening of April 2d the hemorrhage had ceased; her pulse was good and she seemed entirely comfortable. She improved until the morning of the 9th; hemorrhage again came on. My friend Dr. Wallace was called. I was again sent for on the evening of the 9th. We decided the only hope for the mother's life was the delivery of the fetus. Upon examination it was found to be a case of placenta previa; the placenta being attached to neck of the uterus. The hemorrhage was profuse. The vagina was plugged with lint, and fl. ext. ergot (Squibb's), 15 gtt., was ordered every half-hour. Vomiting soon came on, and it was with difficulty she retained anything on her stomach. At 5 o'clock P.M., the 9th, the hemorrhage still continued; she had slight labor-pains. We thought best to rupture the membranes; the lint was removed from the vagina, a gum catheter introduced, and the mem-

branes ruptured. The hemorrhage was now frightful. She sank; was almost pulseless; her extremities were cold. We used whiskey and tinct. opii *freely*; there was but little improvement until about 11½ o'clock P.M.

I succeeded in pushing the placenta back into the uterus; the head of the fetus presented, and the hemorrhage was entirely arrested. At 12½ A.M., the 10th, she was delivered of a dead child. The placenta was removed immediately, and the hemorrhage controlled with cold water and tannic acid introduced into the uterus by syringe. At this time, April 24th, she is doing well; no chills or fever followed.

In this case did the tinct. opii and acid sulph. aro. control the hemorrhage?

Did the excessive use of ergot cause the child's death?

I believe the tinct. of opii the very best stimulant in such cases.

J. ALEXANDER LA RUE, M.D.

HILLSBORO, POCAHONTAS CO., W. VA.

COMPARATIVE SIZE OF GRADUATING CLASSES IN MEDICINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—By the politeness of those in authority, I this morning received the annual announcement of the Medical Department of the University of the City of New York, for the session of 1879-80. By this showing the future outlook of this old and time-honored institution is certainly a brilliant one, and its friends have great cause for congratulation at its prosperous condition.

The announcement contains one slight error which with your permission I will correct.

In instituting a comparison between the number of its graduates of class '79 with that of other institutions (of a similar kind), it is claimed to be the largest class ever graduated by any medical college in the United States.

I have now lying before me the catalogues of the graduating classes of Jefferson Medical College for the years of 1855 and 1856 respectively.

The former class numbered 257 and the latter 215, while that of the University numbered 204.

This is of no special importance to any one, and I write this only that the truth of history may be vindicated while the error is still fresh.

Very respectfully,

J. W. HAMILTON, M.D.

437 CLASON AVE., BROOKLYN, N. Y.

New Instruments.

COMBINED TABLE AND LOUNGE.

BY JAMES L. LITTLE, M.D.,

OF NEW YORK.

FIGURE 1 represents the lounge when closed. It is made without a back, so that the surgeon can stand on either side to examine a patient. The upholstered part is made in a separate piece, and connected with the frame by four upright supports working on pivots at each end to allow of raising and lowering by a leather tag or loop. It is hard and firm, without springs, stuffed with hair, and covered with leather or enamelled cloth.

Fig. 2 shows the lounge converted into a table. The top is kept from falling by a flat iron hook.

FIG. 1.

The weight is so nicely adjusted that a person can sit on the extreme end without danger of its tilting. In

FIG. 2.

this position it can be used for gynecological purposes. Two sliding wooden foot-rests should be illustrated in the end of the movable frame, which may be drawn out if needed, and a drawer may be placed between them. There is also space enough in the lower frame for a pillow, sheets, towels, etc.

This table and lounge is made for the profession by F. Hayack & Co., 615, 617, 619 Tenth av., New York.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 6 to July 12, 1879.

MCKEE, J. C., Major and Surgeon, Medical Director, Dept. of Arizona. His leave of absence granted him in S. O. 64, C. S., from these headquarters, extended fifteen days. S. O. 74, Dept. of Arizona, June 25, 1879.

CLEARY, P. J. A., Capt. and Asst. Surgeon. Granted leave of absence for five months. S. O. 157, A. G. O., July 7, 1879.

MUNN, C. E., Capt. and Asst. Surgeon. Granted leave of absence for four months. S. O. 159, A. G. O., July 9, 1879.

PAULDING, H. O., 1st Lieut. and Asst. Surgeon, now awaiting orders at Washington, D. C. Assigned to temporary duty at Fort McHenry, Md., relieving Asst. Surgeon W. B. Brewster. S. O. 160, A. G. O., July 10, 1879.

BREWSTER, W. B., 1st Lieut. and Asst. Surgeon. When relieved to report by letter to the Surgeon-General. S. O. 160, C. S., A. G. O.

Doctors John J. Kane, J. M. Banister, Wm. B. Brewster, Aaron H. Appel, Chas. Richard, and W. F. Carter, having been found qualified by the Army Medical Board, in session in New York City, have been appointed Assistant Surgeons, with the rank of 1st Lieutenant, to date from June 3, 1879.

THE AMERICAN ACADEMY OF MEDICINE.—The annual meeting of the American Academy of Medicine will be held in the city of New York, commencing September 16th.

DR. ROBERTS BARTHOLOW.—The degree of LL.D. was conferred upon Dr. Roberts Bartholow by Mt. St. Mary's College, Emmetsburg, Maryland, at the annual commencement, held June 25th.

QUALIFICATIONS AND REQUIREMENTS FOR ENTERING THE MEDICAL CORPS OF THE U. S. ARMY.—We

publish the following for the information of persons desirous of entering the Medical Corps of the U. S. Army.

[EXTRACT FROM LAWS OF THE UNITED STATES.]

ACT OF CONGRESS, Approved JUNE 30, 1834.

"SEC. 1. *Be it enacted, &c.*, That from and after the passage of this Act, no person shall receive the appointment of Assistant Surgeon in the Army of the United States, unless he shall have been examined and approved by an Army Medical Board, to consist of not less than three Surgeons or Assistant Surgeons, who shall be designated for that purpose by the Secretary of War, and no person shall receive the appointment of Surgeon in the Army of the United States unless he shall have served at least five years as an Assistant Surgeon, and unless, also, he shall have been examined by an Army Medical Board constituted as aforesaid."

ACT OF CONGRESS, Approved JUNE 23, 1854, and June 26, 1856.

"SEC. 4. That the Medical Department of the Army shall hereafter consist of one Surgeon-General. One Assistant Surgeon-General. . . . One Chief Medical Purveyor, four Surgeons, with the rank, pay, and emoluments of Colonels, two Assistant Medical Purveyors. . . . Eight Surgeons, with the rank, pay, and emoluments of Lieutenant Colonels, Fifty Surgeons, with the rank, pay, and emoluments of Majors. One hundred and twenty-five Assistant Surgeons, with the rank, pay, and emoluments of Lieutenants of Cavalry for the first five years' service, and with the rank, pay, and emoluments of Captains of Cavalry after five years' service. . . ."

All candidates for appointment in the Medical Corps must apply to the Hon. Secretary of War for an invitation to appear before the Medical Examining Board. The application must be in the handwriting of the candidate, stating age and birthplace, and be accompanied by testimonials from Professors of the college in which he graduated, or from other Physicians in good repute. Candidates must be between 21 and 28 years of age (without any exceptions), and graduates of a regular medical college, evidence of which must be submitted to the Board before examination.

The morals, habits, physical and mental qualifications and general aptitude for the service of each candidate will be subjects for careful examination by the Board, and a favorable report will not be made in any case in which there is a reasonable doubt.

The following will be the general plan of the examination:

I. A short essay, either autobiographical or upon some professional subject—to be indicated by the Board.

II. Physical examination. This will be rigid, and each candidate will, in addition, be required to certify "*That he labors under no mental or physical infirmity, nor disability of any kind, which can in any way interfere with the most efficient discharge of his duties in any climate.*"

III. Oral examinations on subjects of preliminary education, general literature, and general science. The candidate must satisfy the board in this examination that he possesses a thorough knowledge of the branches taught in the primary schools, and a failure to show this will end his examination.

Oral examination on scientific subjects will include Chemistry and Natural Philosophy: and that on literary subjects will include English Literature, History of the United States, and General History—Ancient and Modern. Candidates possessing a knowl-

edge of the higher mathematics, the ancient and modern languages, will be examined therein, and due credit given for a proficiency in any or all of these subjects.

IV. Written examination on anatomy, physiology, surgery, practice of medicine and general pathology, obstetrics, and diseases of women and children. Oral examination on these subjects, and also on medical jurisprudence, materia medica, therapeutics, pharmacy, toxicology, and hygiene. Few candidates pay the attention to hygiene which it deserves; it is made an important subject in this examination.

V. Clinical examination, medical and surgical, at a hospital.

VI. Performance of surgical operations on the cadaver.

The Board will deviate from this general plan whenever necessary, in such manner as they deem best to secure the interests of the service.

The Board will report the merits of the candidates on the several branches of the examination, and their relative merit in the whole, according to which the approved candidates will receive appointments to existing vacancies, or to vacancies which may occur within two years thereafter.

An applicant failing one examination, may be allowed a second after one year, but not a third.

No allowance will be made for the expenses of persons undergoing examination, as this is an indispensable prerequisite to appointment, but those who are approved and receive appointments will be entitled to transportation on obeying their first order.

(Signed) GEO. W. McCrARY,
Secretary of War.

WAR DEPARTMENT, November 30, 1878.

BOARD OF EXAMINERS OF THE U. S. MARINE HOSPITAL SERVICE.—The Surgeon-General, Jno. B. Hamilton, of the U. S. Marine Hospital Service, has appointed a Board of Examiners to hold a competitive examination of candidates for the Medical Corps of that service, to commence in Washington, D. C., on the 15th inst. Details for the Board: Surgeon C. N. Ellinwood, President; Surgeon T. W. Miller; Surgeon W. H. Long, Recorder.

TREATMENT OF DANDRUFF.—In answer to inquiries concerning this in the *Lancet*, the words of Abernethy are quoted, "cleanse, dry, and anoint." Cleanse the head every other day with a wash of yolk of egg, and use an astringent lotion of borate of soda and glycerine, $\mathfrak{v}i$. to $\mathfrak{z}i$., with an ointment of creosote every night.

DR. WILLIAM DARLING.—The degree of LL.D. was conferred on Dr. William Darling, of the University of New York, by the University of Vermont at its Annual Commencement, held June 26th.

LEPROSY.—There are thirteen cases of this disease in Louisiana, according to Dr. L. F. Salomon. They are, with one exception, of the tubercular variety. No mode of treatment seems to have been at all efficacious with them.

GRADUATES FROM THE MEDICAL COLLEGES IN THE UNITED STATES IN 1878.—During the year 1878 there were 2,708 medical students graduated from the fifty-nine colleges of the United States.

Original Lectures.

CHRONIC SUPPURATIVE INFLAMMATION OF THE MIDDLE EAR.

A LECTURE DELIVERED AT THE MANHATTAN EYE AND EAR HOSPITAL, IN THE CITY OF NEW YORK.

By O. D. POMEROY, M.D.

(Reported for THE MEDICAL RECORD.)

PART I.

CHRONIC SUPPURATIVE INFLAMMATION OF THE MIDDLE EAR—ETIOLOGY—COLD—EXANTHEMATA AND OTHER FEVERS—EXCESSIVE INFLATION OF THE TYMPANUM—ROUGH HANDLING OF THE EAR—IMPACTED CERUMEN—INJECTIONS INTO THE TYMPANUM—NASAL DOUCHE—ACUTE PHARYNGITIS—PNEUMONIA—MODE OF INVASION—OTORRHOEA A MISNOMER—APPEARANCES UPON INSPECTION—CHARACTER AND QUANTITY OF THE DISCHARGE—APPEARANCE OF THE DRUM-MEMBRANE—PECULIAR PULSATION.

GENTLEMEN:—At our last meeting I spoke with reference to acute inflammation of the tympanum. There are a few points yet to be disposed of, but as I wish this evening to develop as thoroughly as possible the subject of chronic purulent inflammation of the tympanum, I will at once pass to the consideration of the causes of this affection.

ETIOLOGY.

In general terms, it may be stated that the causes of chronic suppurative inflammation of the tympanum are almost identical with those of acute inflammation of the tympanum. I will first speak of the effect produced by cold, on the ear, either directly or indirectly.

a. After taking cold there are a great variety of symptoms. The patient may have rheumatism, or fever, or pneumonia, or sore throat, etc. A sore throat is a very common result of taking cold. Sore throat will not produce otitis necessarily. Anyone with inflammation of the upper pharyngeal space is liable to an attack of otitis, the inflammation traveling up the Eustachian tube, and involving the tympanum.

b. A draught of air upon the head or upon the ear. Under these circumstances the inflammation involves the tympanum by means of the meatus auditorius externus. Direct exposure of the ear to draughts of cold air, such as arise from sitting by an open window, or more especially in a railway car near an open window, listening at a key-hole, etc. It is well known that conjunctivitis is sometimes dependent upon a draught of cold air coming in immediate contact with the eye from the patient's looking through a key-hole. In the same manner inflammation of the ear may be produced by exposure to a draught of cold air while listening at a key-hole.

c. Cold water in the ear from bathing. This may operate as a cause in producing inflammation of the ear in a twofold manner. There is first the effect produced by the application of cold to the ear, and second the violence inflicted. For example, when a person dives, the concussion of the water upon the drum-membrane may inflict sufficient violence to cause its rupture. Or in surf bathing a breaker may strike the ear violently. In such a case we have the double influence of cold and violence in the produc-

tion of inflammation. Water may also pass up the Eustachian tubes from being taken into the mouth in considerable quantity, which the patient often swallows.

Second.—The exanthemata and other fevers. The worst cases of otitis media, produced by the exanthematous fevers, occur in connection with scarlet fever, and in nearly every instance the ear trouble depends upon the sore throat which accompanies the disease. This form of otitis is frequently of a very grave nature. It is very likely to destroy a considerable portion of the drum-membrane, the ossicles may be removed by ulceration, and in other ways extensive damage may be done to the ear. Occasionally in scarlet fever the inflammation travels from the skin down the external meatus, and involves the ear from that direction; but these cases are quite infrequent.

In measles, as you all know, there is a disposition to the development of catarrhal inflammation of mucous membranes. Catarrhal conjunctivitis and nasopharyngeal catarrh, often dependent on this disease, and the pharyngeal catarrh may travel up the Eustachian tube and produce otitis media in the same manner as in the sore throat associated with scarlet fever. The eruption of measles may also extend down the external auditory canal, and involve the tympanum externally.

The same observations may be made with reference to typhus, typhoid, and other fevers, but as a rule the inflammation which is to produce otitis media is first developed in the throat. In small-pox the tympanum is somewhat more likely to become involved by way of the external auditory canal than in the exanthematous fevers.

Third.—Violence inflicted upon the meatus or upon the tympanic cavity.

a. Excessive inflation of the tympanum, which may even rupture the drum membrane. This is a somewhat infrequent cause. You have, however, frequently had opportunities to see how the drum membrane is reddened by inflation of the tympanic cavity. You have seen, as an occasional result of inflation, pain in the ear, produced simply by the violence with which the air has been forced into the tympanum. Since Politzer's method came into use, inflation of the tympanum has been somewhat overdone. I feel sure, if it does not excite inflammation it is likely to stretch the drum membrane in such a manner as to cause it to lose its normal elasticity. Occasionally we see a drum membrane, in an ear that has been inflated excessively, which flaps to and fro like a loosely-fastened sail. Rupture of the membrane, produced by excessive inflation, is not a serious accident, because the tendency existing in the membrane to heal is so strong that it is scarcely possible to prevent it from closing again directly.

b. Any rough handling of the ear, such as may result from improper efforts at removal of cerumen or foreign bodies. I have previously said considerably to you regarding the damage liable to be done by resorting to other means than the syringe in removing cerumen and foreign bodies from the ear.

Some of you have observed that when a given drum membrane is first examined, it may not be reddened, but after three or four examinations have been made, it has been discovered that a good degree of hyperemia has been developed. This has been brought about directly by violence inflicted in the management of the speculum, and otherwise handling the ear roughly. If you ever have had your own ears examined, you doubtless recollect how sensitive an organ the ear is, and how easily irritation sufficient to

throw it into a state of pain and inflammation may be produced.

c. The presence of *impacted cerumen*. In a report which I made several years since of a number of cases of impacted cerumen, I directed attention to the fact that inflammation of the middle ear was caused not very infrequently by the presence of a plug of cerumen in the external auditory canal. The plug acts as a foreign body. The manner in which the violence is inflicted may be as follows: whenever the jaw moves the condyle presses against the meatus, and for the time being narrows its calibre. If, therefore, the canal is filled, or perhaps only partly filled, with hard cerumen, any pressure will inflict violence upon the wall of the external auditory canal, on account of the presence of the hardened cerumen.

4. Injections into the Tympanum.

a. Accidental injections from the use of the nasal douche afford us an example under this head; whether the water is hot or cold, properly salted or not, and I was almost ready to say, whether properly injected or not, we are liable to have trouble. Certain it is that many of us here have caused acute inflammation of the tympanum by the use of the *nasal douche*, and we have probably used it in a reasonably careful manner. It is not always possible to prevent the patient from swallowing while the nasal douche is being used, and if he does swallow, he is liable to have water thrown into the tympanum. Water introduced in that manner does not necessarily excite inflammation. Nothing can be more bland than quite warm water, containing not more than a drachm of salt to the pint, yet occasionally it will produce acute inflammation of the middle ear of considerable violence. Not long since I had a patient from the country, who said that the physicians in his village were using the nasal douche extensively in the treatment of catarrh, and it was pretty generally known among the people that those upon whom it was used were frequently deafer than prior to the commencement of treatment. I use it much less frequently than formerly, and I suspect its general use is being abandoned.

b. Any injection used to relieve a catarrhal condition of the Eustachian tube and middle ear, may, when not desired, pass into the tympanum. This has happened with the Eustachian catheter, and with my Faucial catheter, and it is sometimes quite unavoidable. It is a very good rule to use such a small quantity of the solution, whatever it may be, that it is impossible to reach the tympanum in injecting it. I think I have the same prejudice against injecting the tympanic cavity that has been entertained with regard to injecting the cavity of the uterus. If the drum membrane is perforated, there may be no objection to injecting the tympanum, nay, it may be strongly recommended.

Fourth.—Any inflammation of the pharynx whatsoever, is liable to travel up the Eustachian tubes, and thus give rise to inflammation of the middle ear.

Acute pharyngitis may be developed in a healthy person in consequence of exposure. It is especially liable to be developed in one who suffers from chronic naso-pharyngeal catarrh. As you are all aware, the tuberculous condition gives rise to sore-throat, and it is somewhat analogous to that condition which gives rise to chronic catarrh in general. In these cases the destruction of drum membrane is apt to be extensive.

Inflammation of the tympanum is sometimes de-

veloped in the course of a *pneumonia*. In this condition it depends upon the air being thrown violently into the cavity of the tympanum through the Eustachian tubes during the rapid respiration incident to the lung trouble.

MODE OF INVASION.

The mode of invasion of this affection is as follows: it begins where the acute inflammation ends. The tendency of acute inflammation of the tympanum is toward self-limitation and recovery. There is frequently a tendency to resolution. Thus, if there is a formation of muco-pus or pus in the tympanum, it does not necessarily follow that rupture of the drum membrane will occur. The membrane may be ruptured and heal again directly. If the rupture is small, or is of the form of a fissure, it is likely to heal at once. If it is large, and there is a considerable loss of tissue, it is not as likely to heal. The rapidity with which these ruptures heal, or whether they heal at all, is determined very largely by the condition of the patient. If he is in good general health, if there exists a strong tendency to tissue repair, he will recover from his acute attack completely; but if not, it will pass into the chronic suppurative form. In cases where the perforation is large, the entrance of atmospheric air from the meatus into the cavity of the tympanum has a tendency to perpetuate the disease. The function of the drum membrane is not too well understood, but one part, at least, is appreciated, namely, it protects the sensitive parts of the tympanic cavity from the influence of irritating agents which might enter through the external meatus. The delicate membrane lining the tympanum does not bear well the irritation incident to sudden changes in temperature of the atmosphere, and one of the functions of the drum membrane is to protect it from that source of irritation.

This affection is frequently called *otorrhœa*, and was spoken of by the older writers under that head. This is a misnomer, and should be abolished from the nomenclature of diseases of the ear. The *otorrhœa* is simply a symptom. There is always a discharge in this disease, although the patient will frequently deny its existence. There may be a discharge so small in quantity as not to be appreciated by the patient, hence you should not regard his statement, but should examine the ears carefully. The discharge may be very slight and so gined to the drum membrane that you may be in doubt whether you are looking at the drum-membrane or at the discharge covering it, as the latter may so nearly simulate the color of the membrane itself. If the discharge is large in quantity, you are not *sure* that it comes from the tympanic cavity, but in a large number of instances an excessive discharge comes in part, at least, from the cavity of the tympanum.

APPEARANCES UPON INSPECTION.

There is a profuse ropy mucous discharge. It may be purulent; it may be serous; it may be sanguinolent. Sometimes it will be flocculent, more especially if the patient has granulations or polypi, and probably depends upon the presence of epidermic scales and detached epithelium. The discharge is occasionally of a cheesy consistence, and then it is likely to become more or less agglutinated to the drum-membrane, and requires to be wiped away with absorbent cotton after having been previously syringed. I think you will have observed that but few men in the institution are capable of cleansing an ear as thoroughly and neatly as it should be done. For diagnostic purposes it is of the greatest possible importance

to cleanse the ear very carefully. I advise you to do this under sight aided by the forehead-mirror. Often if the discharge is not all removed, or a few epidermic scales are left, you will be prevented from making an exact examination of the part. When the ear has been properly prepared for examination you will find the membrane more or less reddened, always opaque, grayish in color, dermoid layer mostly or wholly removed by inflammation and maceration. If you will carefully remove the dermoid layer which has not been entirely detached, you will find beneath it a reddened surface which may be dependent, perhaps, partly upon the violence with which you have conducted your manipulations, but principally on the presence of a passive inflammation of the membrane. If the perforation is large, so that you can see the inner wall of the tympanum, it will almost always be found to be red, swollen, and puffy, and will bleed easily. The opposite condition may be present; it will then be pale, relaxed, swollen but little, and accompanied by a thin serous discharge. The latter are rather bad cases to manage. The rupture in the drum membrane may be single, or there may be several openings. The perforation may be located before or behind the handle of the malleus, perhaps most frequently below the centre of the drum-membrane. The membrane may be completely removed. Frequently we see the kidney-shaped perforation with the handle of the malleus extending into the hilus of this opening.

Another point to which I wish to direct your attention, is the sickle-shaped edge of the drum-membrane remaining. Supposing you are inspecting a reddened surface, and you are in doubt as to whether it is the drum-membrane or the inner wall of the tympanum; you will look for a perforation, and by and by you will find a whitish sickle-shaped body at the periphery of the field. That is what remains of the drum-membrane and will enable you to make the diagnosis of perforation with little or no trouble.

In some cases you will see a pulsation in the ear in the vicinity of the drum-membrane; this is well-nigh diagnostic of perforation, and in probably not more than one in fifty cases will you be wrong. If perforation is not present the drum-membrane is very thin. The symptom is explained in this manner: The vessels are very much swollen and the pulsation becomes visible by virtue of the excessively thin covering of membrane lying upon them.

It is worthy of remark that a small portion of the drum-membrane almost always remains, and that is the part above and about the short process of the malleus.

The ossicles are infrequently removed. If any are absent it is likely to be the malleus, although the manubrium alone may be lost by necrosis. The stapes is the last bone to be removed, and its absence is rarely observed. You may be able to demonstrate the presence of the stapes by means of a probe which touches an immovable bony elevation in the region of the oval window. Occasionally it can be seen as a rounded elevation, slightly above and behind the termination of the handle of the malleus; in other words exactly opposite the termination of the long shank of the incus. It is quite generally believed that destruction of the drum-membrane and loss of the ossicles produces profound deafness, but I would state here that the drum-membrane may be all swept away and the ossicles removed certainly the malleus and the incus, without greatly impairing the hearing.

(To be continued.)

Original Communications.

REMARKS ON OVARIOTOMY.

VALUE OF EARLY RECTAL USE OF QUININE AND OPIUM IN CONJUNCTION WITH FREE SUPPORTING DIET, AS MEANS OF DEFENDING THE SYSTEM AGAINST THE DANGERS OF THE OPERATION—ILLUSTRATED BY A SERIES OF SIX SUCCESSFUL CASES, THREE SINGLE AND THREE DOUBLE.

By NATHAN BOZEMAN, M.D.,

Surgeon to the Woman's Hospital of the State of New York.

PART II.

This brings us to the narration of cases of ovariectomy, and I give a series of six, taken without selection, as they presented themselves in my service at the Woman's Hospital within a period of eleven months. From these reports it will be seen that I gradually reached my plan of preparatory and after-treatment, and therefore it will be found carried out to the letter only in one or two of the last cases. The originality or novelty of this treatment, if there be any, will be found mainly in the early and continuous use of quinine and opium per rectum, in conjunction with free and liberal support of the system by oral or rectal alimentation, or both at the same time, as means of preventing or controlling high temperature after ovariectomy.

The results in these six cases are intended to show the value of the plan. All six of the operations were performed in the two small frame cottages situated on the hospital grounds, where the patients were nursed and cared for until all danger had passed—eight to ten days. One week from the completion of the operation being the special period of treatment, the notations of the pulse and temperature for this time were made upon an average once in three hours, but to make these reports as short as possible, only two in the twenty-four hours are here recorded—namely, at or about 6 a.m. and at or about 6 p.m. The quantities of medicines, nutriments, stimulants, etc., given at long, short, or irregular intervals are noted only for the twenty-four hours commencing and ending at 12 o'clock at night. Sulphuric ether was the anæsthetic employed.

CASE I.—Both Ovaries Involved—Right, Seat of large Dermoid Cyst—Never tapped—The Value of Dulness on Percussion over one Ovary, as Diagnostic of the Side of the Tumor, Confirmed—Double Ovariectomy with Antiseptic Precautions—Median Incision—Extensive and Resisting Parietal and Omental Adhesions—Moderate Hemorrhage—Both Pedicles Ligatured—No Drainage-Tube used—Early Supporting Diet—Peritonitis Violent—Compresses of Cold-Water Affusions upon Kibler's Cat forty-eight Hours after Operation—Supplemented by Quinine twenty-four Hours later—Collapse Produced without Reduction of Temperature—The Former Suspended and the Latter Continued—Cinchonism at the End of ninety-six Hours followed by Permanent Reduction of both Pulse and Temperature—Protracted Recovery.

Sarah C., of Perth Amboy, N. J.; native of Ireland, aged thirty-five; married; one child; widow thirteen years; about medium stature; dark complexion, black hair, with the *facies ovariana* well marked; was admitted to the Woman's Hospital May 6, 1878. She

stated that the tumor from the first lay to the right side and was the size of a child's head before it began to occasion serious inconvenience; that nine months previously it began to grow rapidly, and that from this date on she gradually lost flesh. Girth below the umbilicus, $34\frac{1}{2}$ inches. Tumor prominent to the right of the median line, though marked dullness found to the left of the latter in the hypogastric and iliac regions. Slight œdema over the abdomen, and protuberance of the umbilicus. But little mobility of the abdominal walls over the tumor. Dullness on percussion over the right loin pointing directly to the corresponding ovary as the seat of the tumor. Case examined by two of my colleagues, and both concurred with me in the belief that the tumor was ovarian.

Operation, May 13th.—At 2 o'clock, with a cloud of carbolic spray falling upon her abdomen, the necessary incision in the linea alba, below the umbilicus, was made and the peritoneal cavity reached. Owing to the extensive adhesions found, and the difficulty of manipulating the tumor, the incision afterward was extended about an inch above the umbilicus. The adhesions were then all torn or separated with the fingers and handle of the scalpel. Then, by successively tapping the several cysts within the tumor containing fluids of varied densities and colors, the whole mass was so reduced that it could be easily drawn out of the abdomen. It proved to be the right ovary as diagnosed, and the pedicle, after being tied with a carbolized ligature, was cut and dropped. Commencing cystic degeneration of the left ovary now being discovered, this was removed in like manner. There was no great loss of blood, but one or two small bleeding vessels in the omentum required ligatures. The greatest care was taken to wipe out and cleanse thoroughly the abdominal and pelvic cavities. The sponging was continued as long as there was any oozing. The wound by mistake was closed with ten plain silk sutures instead of carbolized ones, and then dressed according to the method usually employed by Mr. Lister. Tumor and contents weighed $18\frac{1}{2}$ pounds; it was dermoid in character, and contained both hair and teeth. Duration of the operation, fifty-six minutes.

AFTER-TREATMENT.

Per orem: Milk, $\frac{5}{8}$ ij. Per rectum: Liq. opii comp., 3 ss.

Evening: Pulse, 132; temp., $103\frac{1}{4}^{\circ}$ F. General condition: Nausea and slight vomiting; neither pain nor tympanitis.

May 14th.—Morning: Pulse, 96; temp., $100\frac{3}{4}^{\circ}$ F. Per orem: Beef-tea, $\frac{5}{8}$ vi.; milk, $\frac{5}{8}$ xiv.; milk porridge, $\frac{5}{8}$ x.; whiskey, $\frac{5}{8}$ ss.; mixture of citrates of potash and lithia every three or four hours. Per rectum: Liq. opii comp., 3 j. General condition: No pain except in the back; slept well most of the night, and a good deal during the forenoon; urine thick and of a yellowish color. Early in the afternoon symptoms of marked peritonitis began to show themselves.

Evening: Pulse, 120; temp., $103\frac{3}{4}^{\circ}$ F.

May 15th.—Morning: Pulse, 100; temp., 102° F. Per orem: Beef-tea, $\frac{5}{8}$ xvi.; milk porridge, $\frac{5}{8}$ xviii.; milk, $\frac{5}{8}$ ij.; whiskey, $\frac{5}{8}$ iss.; mixture of potash and lithia as before stated. Per rectum: Liq. opii comp., 5 i. General condition: At 2 A.M., pulse 120; temp., $103\frac{3}{4}^{\circ}$ F. Now commenced the use of cold-water affusions over the abdomen upon Kibbe's cot at 67° F., six given during the day; each time followed by chilliness and a depressed feeling; pulse small and feeble; tympanites and pain over the entire abdomen.

Evening: Pulse, 110; temp., 103° F.

May 16th.—Morning: Pulse, 116; temp., $101\frac{1}{4}^{\circ}$ F. Per orem: Beef-tea, $\frac{5}{8}$ xiv.; milk porridge, $\frac{5}{8}$ xxij.; milk, $\frac{5}{8}$ xxij.; whiskey, 3 vij.; mixture of potash and lithia as before. Per rectum: Liq. opii comp., 3 i.; sulph. quinine, grs. xxiv. General condition: At 12.45 P.M., when two douches had been given, the pulse and temperature showed an elevation of 126 and $104\frac{1}{4}^{\circ}$ F. respectively; all the symptoms of violent peritonitis present. After a chill, now lost confidence in the cold affusions and concluded to supplement them with sulph. quinine per rectum, in 8-grain doses. From this time to 10 P.M. patient got eight douches, nearly one upon an average per hour. Now temp. $103\frac{3}{4}^{\circ}$ F. Douching suspended for the time.

Evening: Pulse, 120; temp., $103\frac{3}{4}^{\circ}$ F.

May 17th.—Morning: Pulse, 106; temp., $101\frac{1}{4}^{\circ}$ F. Per orem: Beef-tea, $\frac{5}{8}$ xxxvi.; chicken broth, $\frac{5}{8}$ xviii.; milk, $\frac{5}{8}$ vi.; milk porridge, $\frac{5}{8}$ xx.; whiskey, $\frac{5}{8}$ iij. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., 3 iiss. General condition: At 6.30 A.M., made an early visit, and found the patient in a state of collapse. A violent chill was upon her, and her extremities were of icy coldness. The blueness of the lips, the chattering of the teeth, and the almost imperceptible pulse at the wrist all pointed to speedy dissolution. This condition was brought about, as was soon discovered, by wet sheets, wet clothing, and neglect of the nurse, for several hours, to refill with hot water the tin cans around the chest and extremities. By prompt attention to the latter, and changing the sheets and clothing, together with free administration of stimulants, the danger was averted. Thus seeing the great danger attending the use of cold-water affusions, and their failure so far to control, or even moderate high temperature, I determined to abandon them entirely, and trust to quinine and opium per rectum, with free nourishment of the system. Up to this time the two medicines had been given separately, but now they were combined. At 1.30 P.M., about twenty-four hours after their commencement, and when only forty grains of the former and one drachm of the latter (liq. opii comp.) had been taken, through *cinchonism* manifested itself. Patient now hungry. Pulse and skin fair; urine better. Has not slept much during the day, and is afraid to be left alone.

Evening: Pulse, 118; temp., $100\frac{3}{4}^{\circ}$ F.

May 18th.—Morning: Pulse, 104; temp., 101° F. Per orem: Beef-tea, $\frac{5}{8}$ xvi.; chicken broth, $\frac{5}{8}$ ij.; milk, $\frac{5}{8}$ xxx.; milk porridge, $\frac{5}{8}$ xvi. Per rectum: Sulph. quinine, grs. xvi.; liq. opii comp., 3 iiss. General condition: Has slept but little since morning. Talks to herself, and sings. Says she feels first-rate; urine clear; pulse good; tympanites and abdominal pain less.

Evening: Pulse, 100; temp., $100\frac{3}{4}^{\circ}$ F.

May 19th.—Morning: Pulse, 90; temp., 100° F. Per orem: Beef-tea, $\frac{5}{8}$ xxiv.; milk, $\frac{5}{8}$ xvi.; milk porridge, $\frac{5}{8}$ xxxii.; chewed and swallowed the juice of a piece of beefsteak. Per rectum: Sulph. quinine, grs. xvi.; liq. opii comp., 3 i. General condition: Slept pretty much all night; has some nausea and a little dryness of the tongue; also a little pain. Perspires freely when asleep. Sutures removed, and suppuration found in the tracks of nearly all of them. Patient changed from Kibbe's cot to her bed.

Evening: Pulse, 104; temp., 101° F.

May 20th.—Morning: Pulse, 97; temp., $100\frac{1}{4}^{\circ}$ F. Per orem: Beef tea, $\frac{5}{8}$ xvi.; milk, $\frac{5}{8}$ xl.; milk porridge, $\frac{5}{8}$ xvi. Per rectum: Sulph. quinine, grs. xij.; liq. opii comp., 3 iiss. General condition: Tongue

still a little dry; less tympanites; frequent desire to urinate, though quality of urine good.

Evening: Pulse, 103; temp., 101° F.

The same general plan of treatment as set forth in the above diary of the week was continued, with such omissions and changes as regards medicines and food as circumstances from time to time demanded, until the seventeenth day of the operation. Now, the quinine and opium given up to this time by the rectum were stopped.

Up to the tenth day of the operation the temperature varied but little from 101° F. Then it fell below 100° F., and the pulse to about 80. But still there continued every evening to be a slight exacerbation of the little fever present, until June 4th, the twenty-second day, when both the pulse and temperature mounted to 100 respectively. This went on for four or five days, and then subsided gradually to the standard of health. This I attributed to the presence of inflammatory products in the peritoneal cavity. During the week of active treatment, nine and a half drachms of liq. opii comp. were taken, and from the time it was commenced, on the third day, eighty-eight grains of quinine; from first to last, twenty-one and a half drachms of the former, and one hundred and ninety grains of the latter were taken. Week's average of pulse, 106; of temp., 101½. Convalescence finally complete, and the patient discharged cured.

Case II.—Both Ovaries Involved—Main Tumor Myxofibromatous—Ascites—Never Tapped—Absence of Dullness on Percussion over One Loin—Double Ovariotomy with Antiseptic Precautions—Small Incision—Few, but very Resisting Adhesions—Hemorrhage Slight—Shock Considerable—Both Pedicles Ligated—No Drainage-Tube Used, but a small Tent left in Lower Angle of the Wound—Early Supporting Diet by the Mouth and Rectum—Peritonitis Moderate—Quinine with Opium, Commenced per Rectum Thirty Hours after Operation—No Cinchonism—Primary Fever Slight—Secondary High—Pus Discharged through the Wound on the Ninth Day—Peritoneal Cavity Daily Washed out—Prolonged Recovery.

Mary McC., of New York, aged 45, unmarried; short, and of heavy build; lymphatic temperament, with sallow or waxy complexion—was admitted to the Woman's Hospital, May 3d, 1878, presenting an abdominal tumor, with girth below the umbilicus of thirty-seven inches. She stated that a year before admission she first noticed a small tumor low down in the abdomen, and that ever since then she had had pain in the left hip, groin, and corresponding limb; that for six months previous to this time her menstrual flow had been irregular, and sometimes too free; but latterly it had been profuse at times, lasting two or three weeks, for which relief was sought in the St. Vincent Hospital.

Examination showed the tumor to be semi-solid in character, and surrounded by a considerable quantity of fluid in the peritoneal cavity. The precise nature of this floating tumor, for such it was, did not appear clear to my mind, nor were my colleagues, Drs. Emmet and Thomas, who kindly examined the case at my instance, any more decided in their opinions of it. We all agreed, however, upon the two essential points presented by the case: first, that the tumor was connected with the uterus, probably the left side, by a pedicle of no great thickness, and that an operation for its removal was called for. The uterus itself measured three inches, was a little ante-flexed, and drawn over to the left side. The marked

dullness on percussion over the left loin as contrasted with the right, pointed to the corresponding ovary as the seat of the tumor.

Operation, May 17th.—At two o'clock the operation was performed under the antiseptic spray. Through the small incision made in the peritoneal cavity about a gallon and a half of straw-colored fluid escaped, and thus was the oblong semi-elastic tumor brought into view, lying mainly to the left side, but reaching considerably to the right, above the umbilicus. It was found firmly adherent to the left abdominal wall, and it was only after considerable delay and a process of tearing or gnawing through the points of resistance with the fingers and handle of the scapel, that the mass was finally separated. Only one point was cut with the scissors. The tumor was then tapped with a Spencer Wells's trocar, but no fluid escaped. The instrument was then withdrawn, and one finger after another introduced into the opening, until the whole hand penetrated the mass and reduced it to a mere shell. Afterwards it was easily drawn through the opening, and found to be the right ovary instead of the left, as diagnosed. After tying, cutting, and dropping the pedicle in the usual way, commencing disease of the left ovary was found to exist; its pedicle was treated in like manner. This being done, the fine bleeding points in the omentum were tied and the peritoneal cavity cleansed in the most thorough manner. The patient now became so exhausted as to require cessation of the anæsthetic, and four hypodermics of whiskey (ʒiv.) were given. On the establishment of reaction the abdominal wound was closed with eight to ten waxed carbolized sutures, made to include the peritoneum. A tent of carbolized gauze was left in the lower angle of the wound, and to the whole was then added the Lister dressing.

From the semi-solid or friable nature of the tumor, and the general appearance of its structure, I was inclined to regard it as the colloidal variety of cancer; but under the microscope it proved to be of a myxofibromatous character, and therefore benign. The weight of the growth was four pounds. Time of the operation, sixty-two minutes.

AFTER-TREATMENT.

Per orem: Immediately after operation brandy-and-water given freely. Afterward brandy, ʒij. Per rectum: Beef-tea, ʒij. Two hypodermics of Magendie's sol. of morph., given through mistake, instead of liq. opii comp. General condition: Complains of pain in the abdomen, and has some nausea and vomiting. Reaction satisfactory.

Evening: Pulse, 108; temp., 99½° F.

May 18th.—Morning: Pulse, 98; temp., 100½° F. Per orem: Milk, ʒiv.; milk porridge, ʒij.; brandy, ʒij. Per rectum: Sulph. quinine, grs. viij.; liq. opii comp. ʒij.; beef-tea, ʒviiij. General condition: Complains still of pains in the abdomen; has acid eructations; urine clear.

Evening: Pulse, 108; temp., 101½° F.

May 19th.—Morning: Pulse, 102; temp., 101½° F. Per orem: Chicken broth, ʒiv.; tinct. ginger in five-drop doses. Per rectum: Sulph. quinine, grs. xvi.; liq. opii comp., ʒiiss.; beef-tea, ʒx. General condition: Does not vomit, but has frequent eructations, which disturb sleep; has some tympanites and borborismus; passes flatus now and then.

Evening: Pulse, 100; temp., 100° F.

May 20th.—Morning: Pulse, 88; temp., 101½° F. Per orem: Chicken broth, ʒx.; tinct. ginger. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., ʒiiss.; beef-tea, ʒxviij. General condition: Passes

flatus freely, and has less eructation; sleeps well; menstruates a little.

Evening: Pulse, 82; temp., 100 $\frac{3}{4}$ ° F.

May 21st.—Morning: Pulse, 80; temp., 99 $\frac{1}{4}$ ° F. Per orem: Chicken broth, $\frac{3}{4}$ xxxi.; tinct. ginger. Per rectum: Sulph. quinine, grs. xvi.; liq. opii comp., $\frac{3}{4}$ iss.; beef-tea, $\frac{3}{4}$ xi. General condition: Still menstruates; feels very well in every particular. The gauze tent is removed from the lower angle of the wound. About one ounce of clear, thin, yellowish fluid followed it. The opening was drawn together with an adhesive strip.

Evening: Pulse, 80; temp., 100 $\frac{1}{4}$ ° F.

May 22d.—Morning: Pulse, 88; temp., 100° F. Per orem: Chicken broth, $\frac{3}{4}$ xxxij. Per rectum: Sulph. quinine, grs. xvi.; liq. opii comp., $\frac{3}{4}$ ij.; beef-tea, $\frac{3}{4}$ xi. General condition: Stomach quiet; sleeps well; sutures all removed; wound united down to the site of the gauze tent; no suppuration in the tract of the sutures.

Evening: Pulse, 84; temp., 100 $\frac{1}{4}$ ° F.

May 23.—Morning: Pulse, 92; temp., 100 $\frac{1}{4}$ ° F. Per orem: Chicken broth, $\frac{3}{4}$ xxxix.; beef-tea, $\frac{3}{4}$ xvij. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., $\frac{3}{4}$ ij. General condition: Satisfactory in every particular.

Evening: Pulse, 88; temp., 100 $\frac{1}{4}$ ° F.

May 24th.—Morning: Pulse, 90; temp., 99 $\frac{1}{4}$ ° F. Per orem: Chicken broth, $\frac{3}{4}$ xix.; beef-tea, $\frac{3}{4}$ xix. Per rectum: Sulph. quinine, grs. xij.; liq. opii comp., $\frac{3}{4}$ iss. General condition unchanged.

Evening: Pulse, 92; temp., 99 $\frac{3}{4}$ ° F.

On the eighth day after the operation the patient was removed from the cottage to the hospital, there being a slight increase of pulse and temperature the previous day. About eighteen hours later—pulse, 105; temp., 103 $\frac{1}{4}$ ° F.—her condition became exceedingly critical on account of pyemic symptoms, but, fortunately, now the smaller track of the tent in the lower angle of the wound reopened and gave vent to about one ounce of purulent and very offensive fluid from the peritoneal cavity. This resulted after a couple of days in the dropping down of the pulse and temperature to 72 and 99 $\frac{1}{4}$ ° F. respectively. The washing out of the peritoneal cavity two or three times daily was now commenced with a weak solution of common salt and a little carbolic acid, as recommended by the late Dr. Peaslee. For twenty days this discharge continued, seemingly from the locality of the left broad ligament, varying in quantity, and at intervals more or less long, from a teaspoonful to half a teacupful. It was, as already stated, exceedingly offensive, and sometimes more so than at others. From the sixteenth to the twentieth day after the operation the temperature again ranged from 100° to 101 $\frac{1}{4}$ ° F. Then it fell to 99° F., and remained below 100° F. to the complete closure of the wound, which took place on the twenty-eighth day. During the time the wound was discharging, the patient required all the support by the mouth and rectum that it was possible to give. The quinine and liq. opii were continued per rectum, in gradually diminished portions, until the twenty-sixth day of the operation. The quantity of the former taken during the weeks' special treatment was 108 grains, and of the latter 134 drachms; afterward, of the former 216 grains, and of the latter 22 drachms, making in all, from first to last—quinine, 324 grains, and liq. opii comp., 35 $\frac{1}{2}$ drachms. Week's average of pulse, 92; of temp., 100° F.

The patient called upon me at my office about five months after the operation, and said she never felt

better. To all appearances she was in robust health. After recovering from the operation the uterine discharge ceased, and up to this date showed no indication of reappearance.

CASE III.—*Unilocular Cyst of Right Ovary—Never Tapped—The Value of Dullness on Percussion over one Loïn as Diagnostic of the side of the Tumor Confirmed—Ovariotomy with Antiseptic Precautions—Small Incision—Adhesions Unimportant—But little Loss of Blood—No Drainage-Tube—Pedicle Ligatured—Shock from Operation Considerable and Reaction Slow—Free Stimulation—Early and Continuous Support of the System by the Mouth and Rectum—Peritonitis Mild—Quinine with Opium per Rectum Commenced sixteen hours after Operation—No Cinchonism—Fever Slight—Speedy Recovery.*

Mrs. E., of New York, aged 65; tall and slender; mother of two married daughters; widow thirty years; *facies ovariana* pronounced; was admitted to the Woman's Hospital, October 23, 1878, with girth of abdomen thirty-nine inches. She was very much run down in health, and bore the impress of long suffering. First noticed the tumor eighteen months previously in the right side, and within the last eight months lost eighteen pounds in weight. Tumor movable. Fluctuation pronounced. Dullness over right loïn. Diagnosis clear. Never tapped.

Preparatory treatment consisted in regulation of the bowels, daily tepid baths with vascline incunations and nourishing diet, with free allowance of brandy.

Operation, November 1.—At two o'clock the operation, under the carbolic acid cloud, was performed. Small incision. One or two slight omental adhesions. Cyst tapped with the Wells trocar and drawn through the wound. Pedicle as usual pierced, tied with carbolized ligatures, cut, and dropped without hindrance. Tumor of the right side as diagnosed. Peritoneal cavity sponged out until all oozing of blood ceased. Wound closed with waxed carbolized sutures, and then dressed antiseptically. Shock of the operation considerable. Free administration of brandy required. Weight of tumor and contents, twenty-seven pounds. Duration of the operation, twenty-seven minutes.

AFTER-TREATMENT.

Per orem: Brandy given *ad libitum* for several hours, and then at intervals of three hours. Per rectum: Liq. opii comp., $\frac{3}{4}$ i. General condition: Patient suffers considerably from shock of the operation. She rallies slowly under the free use of brandy. Pulse feeble for several hours. No nausea or vomiting.

Evening: Pulse, 88; temp., 96 $\frac{1}{4}$ ° F.

November 2d.—Morning: Pulse, 92; temp., 98 $\frac{1}{4}$ ° F. Per orem: Milk porridge, $\frac{3}{4}$ xvij.; brandy, $\frac{3}{4}$ ij.; tinct. ginger. Per rectum: Sulph. quinine, grs. xxij.; liq. opii comp., $\frac{3}{4}$ ij.; beef-tea, $\frac{3}{4}$ ij. General condition: Complains occasionally of pain. Has recovered entirely from shock of the operation. Pulse full and soft. Skin moist. Stomach still quiet.

Evening: Pulse, 96; temp., 98 $\frac{1}{4}$ ° F.

November 3d.—Morning: Pulse, 84; temp., 98 $\frac{1}{4}$ ° F. Per orem: Beef-tea, $\frac{3}{4}$ ij.; milk porridge, $\frac{3}{4}$ ix.; brandy, $\frac{3}{4}$ xij.; tinct. ginger. Per rectum: Sulph. quinine, grs. xv.; liq. opii comp., $\frac{3}{4}$ iss.; beef-tea, $\frac{3}{4}$ iv. General condition: Slept well during the night. Has no pain. Pulse full, soft, and regular. Skin warm and pleasant. Urine drawn every six hours and is clear. No tympanites.

Evening: Pulse, 85; temp., 99½° F.

November 4th.—Morning: Pulse, 76; temp., 98½° F. Per orem: Beef-tea, ʒvi.; milk, ʒij.; milk porridge, ʒv.; brandy, ʒij.; tinct. ginger. Per rectum: Sulph. quinine, grs. xv.; liq. opii comp., ʒss.; beef-tea, ʒix. General condition: Slept nearly all night. Had to be waked to take medicine and nourishment. Pulse regular, but not strong. Skin soft; urine clear; perspires while sleeping. This evening sleep is disturbed and there is a little restlessness. Opium suspended. Neither tympanites nor borborygmus.

Evening: Pulse, 74; temp., 98½° F.

November 5th.—Morning: Pulse, 72; temp., 97¼° F. Per orem: Beef-tea, ʒxi.; milk porridge, ʒxviiij.; brandy, ʒx. Per rectum: Sulph. quinine, grs. xv.; liq. opii comp., ʒss.; beef-tea, ʒviiij. General condition: Less restless; sleeps very well; pulse and skin good; appetite and digestion good; urine clear and normal; no tympanites; tongue a little dry and coated; very cheerful.

Evening: Pulse, 74; temp., 98½° F.

November 6th.—Morning: Pulse, 76; temp., 98¼° F. Per orem: Beef-tea, ʒxij.; milk, ʒvi.; milk porridge, ʒvi.; brandy, ʒxiv. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., ʒi.; beef-tea, ʒxij. General condition: Sleeps soundly; pulse and skin soft; passes the urine a little more frequently, which is slightly cloudy; slight tenderness of the abdomen, but no tympanites; no rumbling of the bowels or distress in the abdomen of any sort.

Evening: Pulse, 76; temp., 98½° F.

November 7th.—Morning: Pulse, 72; temp., 98¼° F. Per orem: Beef-tea, ʒx.; milk, ʒvi.; milk porridge, ʒix.; brandy, ʒxij. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., ʒi.; beef-tea, ʒxvi. General condition: Satisfactory in every particular; sutures removed; union of the wound found to be complete, excepting one or two superficial points; scarcely any discharge; only from one suture was there a show of pus; antiseptic dressings renewed.

Evening: Pulse, 78; temp., 99½° F.

November 8th.—Morning: Pulse, 72; temp., 98½° F. Per orem: Beef-tea, ʒxviiij.; milk, ʒxxj.; milk porridge, ʒviiij.; brandy, ʒviiij. Per rectum: Sulph. quinine, grs. xviiij.; liq. opii comp., ʒi.; beef-tea, ʒiv. General condition unchanged.

Evening: Pulse, 80; temp., 98½° F.

The same general plan of treatment was continued, excepting the quantity of opium, which was diminished and given at longer intervals. On the thirteenth day after the operation the patient received an enema of warm water, containing a little common salt and castile soap, which resulted in a free movement of the bowels. On the fourteenth day she was removed from the cottage to the hospital building. Now quinine and opium per rectum were discontinued, but the former was given a while longer thrice daily per orem, in two grain doses, as a tonic. During the week's treatment 131 grains of quinine and 10½ drachms of liq. opii comp. were taken, and afterwards 109 grains of the former and 7 drachms of the latter, making in all: quinine, 240 grains, and liq. opii comp., 17½ drachms. Week's average of pulse, 86; of temp., 98½° F. Patient discharged cured.

CASE IV.—*Multilocular Cyst of Left Ovary—Metrorrhagia and Facies Uteri present—Tumor of the Abdomen—Emaciation Marked—The Value of Diets—Dissection over the Left, as Directed by the Surgeon—The Tumor, Cystic—Quinine Used for the Post-operative—Ovariectomy with Anæsthetic—Recovery.*

Resisting, and Intimate with the Mesentery—Hæmorrhage Considerable—Pedicle Ligament—No Drainage-Tube used—Early and Constant Support of the System by the Mouth and Rectum—Opium with Opium Continued per Rectum Three Hours after Operation—Percussion at the End of the Operation—Pain Produced at the end of Eighteen Hours—Pulse and Temperature Controlled—Nausea and Vomiting Prevalent until the end of the Fourth Day—Successful Recovery.

Mrs. T., of New Jersey, aged 47 years; German; medium stature; dark complexion; black hair and eyes; married 27 years; never pregnant; was admitted to the Woman's Hospital November 24, 1878, with girth of the abdomen measuring thirty-nine inches. She first noticed enlargement of her abdomen about a year previously. Menstruation was always profuse but regular before that date. Afterwards it became irregular, and metrorrhagia was the rule. The growth from the first was rapid. In the course of six months it was tapped twice. The first time two gallons and a half were taken, and the second one and a half. Fluid very dark-colored. During the autumn had several attacks of malarial fever, for which she took quinine largely, and since then has lost flesh rapidly. As to the diagnosis, one of my colleagues, who examined the case with me, thought the tumor was fibro-cystic; and, indeed, I thought so myself at first. The metrorrhagia and *facies uteri*, both of which existed in a marked degree, certainly warranted this supposition. Further examination and study of the case, however, satisfied me of the error of this opinion, and led me to conclude that the tumor was a compound cyst of the ovary, most probably the left, and that its surrounding adhesions were extensive and strong. Then dullness on percussion over the left loin. Up to within five or six days of the time set for the operation the patient had a metrorrhagic flow about as usual, though attended with but little elevation of pulse and temperature. From this time on, ten or twelve grains of quinine were given daily, while the patient was otherwise prepared for the operation, as by warm baths, vaseline inunctions, and the unloading of the bowels.

Operation, Dec. 16th.—The operation (antiseptic) was commenced at two o'clock by small incision. After tapping successively the several cysts of the tumor, and separating with the fingers the anterior and lateral attachments of the latter, which were quite resisting, there was still found behind it one point of adhesion to the mesentery, so extensive and unyielding as to require for its separation not only the greatest force of the fingers and handle of the scalpel, but the greatest care to avoid injury of the subjacent parts. The last obstacle being overcome, the tumor in its collapsed state was easily drawn through the wound. It proved to be of the left ovary, as previously diagnosed. The pedicle was secured in the usual way. There being considerable oozing of blood, especially from the mesentery, sponging of the peritoneal cavity was continued for some minutes. The wound was then closed with carbolic suture, made to include the peritoneum, and the external antiseptic dressings were applied. Weight of the tumor and its contents, 17½ pounds. Duration of the operation, fifty-seven minutes.

AFTER-TREATMENT.

Per orem: Nothing. Hypodermic of ʒv. of Magendie's sol. of morphia. Per rectum Sulph. quinine, grs. xx.; liq. opii comp., ʒiij.; beef-tea, ʒiv.

General condition: Has a good deal of pain; vomits a little, and then moans continually. Pulse good.

Evening: Pulse, 108; temp., 99° F.

Dec. 17th.—Morning: Pulse, 104; temp., 98½° F. Per orem: Milk, ℥ij.; milk porridge, ℥xij. Per rectum: Sulph. quinine, grs. xxx.; liq. opii comp., ℥iijss.; beef-tea, ℥iv.; mashed beef and pancreatine, ℥viiij. General condition: Some pain; sleeps nearly all the time; skin warm and pleasant; pulse full and strong; feels a sense of fullness in the epigastrium; urine drawn every six hours; normal in quantity and color; menstruation appears; *cinchonism* at the end of eighteen hours.

Evening: Pulse, 120; temp., 100½° F.

Dec. 18th.—Morning: Pulse 108; temp., 100½° F. Per orem: Milk porridge, ℥x.; brandy, ℥ss.; tinct. ginger occasionally. Per rectum: Sulph. quinine, grs. xl.; liq. opii comp., ℥ij.; mashed beef and pancreatine, ℥xvi. General condition: Slept a good deal during the night; skin warm and pleasant; pulse full and soft; has some hiccough and nausea; once vomited a greenish-looking fluid; has no pain, but feels weak; urine of claret color; four to six ounces passed every six hours; some tympanites and a little abdominal tenderness. Nourishment by the mouth stopped for the present.

Evening: Pulse, 102; temp., 99½° F.

Dec. 19th.—Morning: Pulse, 104; temp. 99½° F. Per orem: Brandy, ℥iij.; coffee and milk, ℥ij.; tinct. ginger. Per rectum: Sulph. quinine, grs. xxx.; liq. opii comp., ℥ij.; mashed beef and pancreatine, ℥xiv. General condition: Sleep is interrupted, though sufficient; some headache; considerable tympanites; has eructation, and vomits a good deal of greenish fluid; tongue a little dry; again has *tinnitus aurium*, and with it slight *narcotism*; pulse and skin good; nourished entirely by the rectum; skin moist and soft.

Evening: Pulse, 102; temp., 99¾° F.

Dec. 20th.—Morning: Pulse, 108; temp., 98½° F. Per orem: Brandy, ℥i.; toast water, ℥v.; tinct. ginger; Hoffman's anodyne, ℥iss. Per rectum: Sulph. quinine, grs. xxx.; liq. opii comp., ℥iij.; mashed beef and pancreatine, ℥xiv. General condition: Drowsy, and sleeps nearly all the time; still has some hiccough, and occasionally vomits a little dark-greenish fluid; tympanites continues; hysterical at times; cries for her husband, and wants beer to drink; urine normal; skin moist and pleasant; pulse good; pupils slightly contracted.

Evening: Pulse and temp. not stated.

Dec. 21st.—Morning: Pulse, 104; temp., 99½° F. Per orem: Milk porridge, ℥v.; toast water, ℥vij.; Hoffman's anodyne, ℥ss.; Magendie's sol. hypodermically, ℥vij., owing to inability of the rectum to retain. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., ℥ss.; mashed beef and pancreatine, ℥vi. General condition: Sleeps a good deal; still a little nauseated, but no vomiting; passed from the rectum to-day one or two portions of the emulsion, and one portion of quinine and opium. Enemata of all sorts stopped at the regular hours for the present; food by the mouth increased; otherwise condition is most favorable; pulse good; skin moist.

Evening: Pulse, 108; temp. 99° F.

Dec. 22d.—Morning: Pulse, 112; temp., 98½° F. Per orem: Milk porridge, ℥xi.; toast water, ℥ij.; Hoffman's anodyne, ℥ss.; tinct. ginger; beef-tea, ℥i. Per rectum: Sulph. quinine, grs. xxx.; liq. opii comp., ℥ij.; mashed beef and pancreatine, ℥viiij. General condition: One portion of quinine and opium rejected by the rectum; hysterical excitement con-

tinues, but otherwise the symptoms are better; bowels moved once; pulse, skin, and urine satisfactory; has still some hiccough and eructations.

Evening: Pulse, 114; temp., 98½° F.

Dec. 23d.—Morning: Pulse 112; temp., 98° F. Per orem: Chicken broth, ℥i.; milk porridge, ℥v.; milk and lime-water, ℥i.; brandy, ℥ij.; toast water, ℥iv.; Hoffman's anodyne, ℥i.; Magendie's sol. morphia hypodermically, ℥vij., because rectum will not retain anodyne. Per rectum: sulph. quinine, grs. x.; liq. opii comp., ℥i.; mashed beef and pancreatine, ℥viiij. General condition: Does not feel so well; more or less restless; bowels have moved once or twice; urine voided in bed several times during the day; dose not like to take food by the mouth; sutures removed, and adhesive strips applied with renewal of abdominal compress. Union of the wound throughout, excepting one small superficial point, with no suppuration in the tracks of the sutures.

Evening: Pulse, 112; temp., 99½° F.

For two days longer the same course of treatment was pursued, when the pulse, for the first time in nine days, dropped below 100. After this the quantity of quinine per rectum was diminished, and a few days later given by the mouth as a tonic. On the tenth day the patient was removed from cottage to the hospital building, and allowed to take all her nourishment by the mouth. For several days after this there was slight irritability of the bowels at times, and an occasional return of the hysterical symptoms; but the general tendency was to a satisfactory convalescence. Quantity of quinine taken per rectum during the first week after the operation, was 210 grains, and of liq. opii comp., 15¾ drachms, with three hypodermics of Magendie's sol. of morphia. Afterward, by the rectum and mouth, 91 grains of quinine, and 5¾ drachms of liq. opii comp. In all, 301 grains of the former, and 21¾ drachms of the latter. Week's average of pulse, 108; of temp., 99° F.

Patient discharged cured.

(To be continued.)

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND ITEMS OF TREATMENT.

ASCITES—DISPLACEMENT OF THE HEART.

THE following case was interesting, chiefly because it illustrated displacement of the heart, by an accumulation of fluid in the abdominal cavity.

A male patient, *æt.* 40 years, entered the hospital January 7, 1879. When admitted his abdominal cavity was distended with fluid. His urine had a specific gravity of 1024, was alkaline, and contained neither albumen nor casts. The accumulation of fluid was so great that the heart was displaced. The patient was tapped, but the fluid had reaccumulated rapidly, and at the time of this note the heart was so displaced that the apex-beat was above the nipple upon the left side.

There was no evidence of cardiac disease. Such displacement of the heart by an accumulation of fluid in the abdominal cavity, was regarded as quite unusual, and showed that the patient had a feeble diaphragm. In most patients the pressure in ascites is exerted at the expense of the anterior abdominal walls chiefly. The liver is displaced upward, but not in the same

proportion as is the heart. The area of hepatic dullness is diminished to two and three-fourths inches. The man probably had cirrhosis of the liver, and the prominent symptom was the dropsy, which came on very rapidly. His abdomen began to swell about one month before admission to the hospital. His feet were also swollen.

The accumulation of fluid in the abdominal cavity in this case was more than usually dangerous because of the tendency to push the diaphragm upward. The leading symptom to be treated was the dropsy; and tapping early, and frequently repeated, was the plan recommended. At the same time such measures were to be adopted as improved and sustained general nutrition.

IDIOPATHIC INFLAMMATION AND THROMBOSIS OF THE SUPERFICIAL VEINS OF THE LEGS.

A male patient, forty years old, who had never had rheumatism, denied venereal, and had never been intemperate, was admitted to the hospital December 10, 1878, complaining of swelling and stiffness of the legs without pain. The chief point of interest in the case was the inflammation and thrombosis of the superficial veins of the legs without known cause. The veins could be felt like cords as the finger passed over them. The treatment had not been energetic. While the inflammation was going on the patient was kept in bed. After the inflammation had subsided, and nothing remained except the œdema and the thrombosis, the legs had been bandaged, and the patient had been improving. The rubber bandage was recommended, for by it the œdema could be almost entirely prevented, and the cure of the case could be made almost complete.

HEMORRHOIDS—OPERATION—DRESSING—METHOD OF CONTROLLING HEMORRHAGE.

A male patient was suffering from internal hemorrhoids. They exhibited the raspberry appearance, and were regarded as the artero-capillary variety. For the purpose of effecting a radical cure they were treated with the double ligature. The sphincter was not dilated. Treatment after the operation was believed to be sufficient to prevent spasm of the sphincter. In cases in which the pile could not be easily surrounded, Sims's speculum was recommended. The operation being completed, a suppository containing opium and belladonna was introduced well above the internal sphincter. A large piece of lint smeared with vaseline was placed over the anus and the cleft of the nates. The cleft was then packed with cotton until it was filled to a level with the tuber ischii; over that a compress was placed, and the whole was retained in position by means of an ordinary T-bandage.

But suppose *hemorrhage* should occur from the stump of the pile or elsewhere? A plan of treatment was recommended which, although not new, is perhaps worthy of description. Of course, effort might be made to tie the bleeding vessel. But the plan recommended as the better one was first to take a cone-shaped piece of sponge, and make it hollow; then pass a thread from the inside through the side of the sponge, over the apex of the cone, and return it to the cavity in the sponge. In that manner a loop was made which placed the sponge within the control of the surgeon. It was then to be slightly moistened, compressed, and pushed up as high as possible in the rectum upon the tip of the finger. Pieces of lint were then to be carried in until the cavity in the sponge was filled. As soon as filled, traction was to be made upon the strings, when the sponge would spread out

and press against the sides of the rectum. In that manner flow of blood upward was prevented, and the compress already described prevented any discharge from the anus. In ordinary cases it was thought advisable to leave the sponge *in situ* for thirty-six or forty-eight hours. If hemorrhage returned, the sponge could be replaced.

ANEURISM OF THE AORTA—TREATMENT BY IODIDE OF POTASSIUM.

A male patient was the subject of aneurism affecting the junction of the transverse with the descending portion of the aorta. After he had taken iodide of potassium in fifteen-grain doses three times a day for a short time, he said that he felt much better, and the heaving movement was distinctly less than before the remedy was commenced.

PERICARDITIS—PLEURISY WITH EFFUSION—DISAPPEARANCE OF AN ENDOCARDIAL MURMUR.

A boy, fourteen years of age, had suffered from rheumatic pericarditis, and at the same time and upon the same side from pleurisy with effusion. Recovery took place, and the patient walked about the hospital feeling nearly as well as ever.

The apex-beat, during the time the pleuritic effusion was present, beat in the fourth intercostal space. All evidence of liquid in either the pleural or the pericardial cavity had disappeared, and the apex-beat was in the fifth intercostal space.

One remarkable feature in the case was the following: a double pericardial friction murmur was developed, and also an endocardial, a mitral systolic non-regurgitant murmur. The endocardial murmur had disappeared, and in that respect the case was regarded as exceptional.

It was probable that complete adhesion would occur between the pericardial surfaces, and the question arose, how much practical importance was there to be attached to that fact? The answer was, that formerly it was considered as a serious result, but latterly the conclusion had been reached that, if there were no co-existent valvular lesions, the heart would continue to perform its functions very well, notwithstanding the pericardial adhesions.

Progress of Medical Science.

NEURASTHENIA AND WOMEN-DISEASE.—According to Dr. Goodell, neurasthenia in women manifests itself by hysteria, spinal irritation, and a crowd of reflex symptoms, among which those of a uterine complexion often predominate. This neurosis probably consists essentially in mal-nutrition of nerve-centres, followed by disturbances in the circulation from weakened innervation (local anemia and hyperæmia). The anemia of the genital organs is exhibited by amenorrhœa, by neuralgic and hysterical pains; the hyperæmia by congestion, dysmenorrhœa, menorrhagia, uterine flexions, and dislocations, and a variety of subjective phenomena.

Thus, many disorders of the reproductive organs are merely the local expressions of the general neurosis. Based upon this principle, Dr. Goodell adopted Weir Mitchell's plan of treatment, as laid down in his work on "Fat and Blood, and How to Make Them," for the class of cases referred to above, and combined this treatment with a local one in those cases of undoubted uterine disease in which the con-

stitutional symptoms were out of all proportion to the local lesions. Dr. Mitchell's treatment consists, as is well known, of rest, massage, electricity, seclusion, and feeding. Dr. Goodell reports the results in several cases under his care, of which the following is an example:

A girl, of twenty, who had been an invalid for five years, was put under treatment on March 11th. At the age of fifteen the patient began to suffer from dysmenorrhœa, back-ache, ovarian hyperæsthesia, frequent attacks of hysterio-epilepsy, disturbances of the bladder, obstinate costiveness, and loss of all appetite. About a year previously the patient had been treated for antelexion, and a tent was introduced into the cervix, which lighted up a very severe attack of peritonitis, after which she became bed-ridden. Upon examination, March 10th, the uterus and ovaries were very tender, the former turgid, antelexed, and bound down by adhesions. On account of the disproportion between the symptoms and the local lesions, Mitchell's treatment was advised, and entered upon the next day. The patient was not allowed to read or write, or see any of her friends, and was at once put on a skimmed-milk diet. The medicinal treatment consisted of the administration of Trommer's extract of malt, dialyzed iron, valerianate of zinc, and an occasional aperient pill. On March 18th she drank four quarts of milk; on March 28th she took four and a half quarts, three boiled eggs, and over two pounds of broiled chicken. Massage and electricity were likewise employed in the manner recommended by Dr. Mitchell. During the forty-five days of treatment she drank 208 quarts of milk, and averaged two and a half eggs daily. During this period she gained twenty-two pounds in weight, and all bad symptoms disappeared entirely. The patient has remained perfectly well ever since. Although rapid increase in flesh is usually regarded as a very trustworthy token of returning health in these cases, yet the success of the treatment does not always depend upon it, as shown by a number of cases treated by Dr. Goodell.

The symptoms in these cases were apparently due to uterine disease, yet the essence of the disease lay in the exhaustion and lack of nutrition of the nerve-centres. The patients give a history of exhaustion, wakefulness, great nervousness, constant back-ache, and ovaralgia. The objects to be secured, therefore, are, nutrition, sleep, rest of body and mind, and freedom from pain. All these indications are met by the plan laid down by Dr. Mitchell, and indicated in the history of the case furnished in the present article.—*Gynecological Transactions*, vol. iii., 1879.

CHARCOT ON THE SOMNAMBULIC AND CATALEPTIC CONDITION IN HYSTERIA.—The patient, a hysterical woman of 21, in one of Charcot's wards, was directed to fix her eyes upon a bright light. In a few seconds she became cataleptic and completely anæsthetic. The limbs were flexible, and assumed any position in which they were placed by the operator. If the hands were placed near the lips, as if in the act of throwing a kiss, the features would assume an "osculatory" expression; if the hands were placed as in a begging position, the face assumed a corresponding expression, etc. These phases have been termed suggestive phenomena, and last as long as the impression of the bright light upon the retina continues.

If the light is removed a condition of somnambulism (hysterical lethargy, Charcot) is produced. If the patient were standing (in the cataleptic state) she would fall backward, the head thrown back, the neck

arched prominently. The eyes are closed, and a whistling inspiration is heard, accompanied by noisy movements of deglutition. Muscular hyper-excitability is induced in this condition; the slight friction of the skin will produce contraction of the underlying muscles. Another feature of this condition is a constant motion of the upper eyelid, convulsions of the globe of the eye in various directions, and persistent anæsthesia. If the patient be loudly spoken to she will arise, direct herself towards the person speaking; she will stand, sew, write, etc.

The eyes are, however, closed or partly closed (the muscular sense seems to replace the sense of sight, M. Azam). The patient answers questions and the intellect seems to be exalted. She is restored to consciousness by merely breathing or blowing on the face, or pressing on an ovary, and has no recollection whatever of what has transpired.—*St. Louis Courier of Medicine*, March, 1879.

NOTES ON THE USE OF THE HÆMACYTOMETER IN ANÆMIA.—We must remember that the hæmacytometer does not compute the number of blood-corpuscles in the body, but rather the proportion which the corpuscles bear to the serum of the blood, and that a great deal also depends upon the quality of the corpuscles, *i. e.*, upon the amount of hæmoglobin which they contain.

In ten carefully examined cases of anæmia the average of the red corpuscles at the onset of treatment was 62 per cent., and in the three worst cases the average was less than 46 per cent. None of these patients were laid up by the disease; and they were all able to walk to the out-patient room.

The corpuscular richness of the blood is seldom accurately represented by the appearance either of the skin or the mucous membranes. In an apparently extreme case of anæmia the patient was confined to her bed, the pulse was very frequent, there were numerous syncopal attacks and frequent vomiting, the face was nearly as pale as a sheet, and the conjunctivæ almost blanched; there was some suspicion of hysteria. Examination of the blood showed the number of corpuscles to be not far from normal, so that the case was not one of anæmia. Under appropriate treatment the patient was well in a fortnight.

Again, the corpuscles reach the normal amount some time before the patient's symptoms have disappeared; *i. e.*, the number of corpuscles may be increased out of all proportion to the increase in their hæmoglobin.

The marked effect of iron in increasing the number of the red corpuscles was well seen in a case of surgical anæmia. A considerable portion of the skull was removed by operation in a patient with a fractured skull. Secondary hemorrhage occurred, at the commencement of which the corpuscles averaged 76 per cent. The hemorrhage continuing, they decreased in a week to 50 per cent., when the common carotid was ligatured. The hemorrhage then ceased but the corpuscles nevertheless diminished in amount to 38 per cent., three days after the operation. The patient was then ordered ferrum redactum, five grains daily, and a nourishing diet. In two days the corpuscles had risen to 50 per cent. and in a fortnight to 100 per cent.—*Lancet*, May 10, 1879.

EXCISION OF PAPILOMA OF BLADDER.—M. C., æt. 34, was admitted to St. Mary's Hospital, under the care of Mr. Norton, suffering from the effects of long-continued hemorrhage from the bladder. On examination per urethra, a tumor one inch square, coated with phosphatic calculus, but not much raised above the mucous membrane, was discovered occupying the

trigone, about half an inch from the sphincter. It was evident that the tumor must be removed, and the patient submitted to the risks attendant upon a severe operation, or she must be left to endure the tortures brought about by the contraction of the bladder upon the growth after micturition, and with the certainty of an early death from hemorrhage, or from blood-poisoning. It was impossible to remove the growth through the urethra, and it was decided to cut the mass away by opening the vagina. It was considered that the growth could not be cleared without cutting through the urethra, and the operation was performed as follows: The spring-scissors were inserted, one blade into the bladder nearly up to the tumor, and the other into the vagina, and closed; the front wall of the vagina was then incised centrally to within half an inch of the uterus, and the vaginal wall, which was found not to be incorporated with the growth, was dissected from the bladder; the growth was then seized with the vulsellum forceps and drawn forward, and was then excised by the scissors and removed. Bleeding was arrested by the actual cautery, and the lateral flaps of the vagina approximated by sutures. To prevent further hemorrhage a catheter was inserted, and the bladder compressed by plugging the vagina; no hemorrhage of importance took place. The temperature remained below normal, and the pulse rose to 120. Severe vomiting persisted until the tenth day after the operation, when she was considered out of danger. On the twelfth day, when apparently in health, she vomited, and shortly afterward fell asleep, in which sleep she died from syncope. At the autopsy the wound was green, and sloughing upon the surface, but healthy immediately beneath. No peritonitis, or cellulitis was present, nor any thrombosis of vesical, pelvic, or iliac veins. A microscopical examination showed the tumor to be a papilloma. Since writing this case Mr. Norton had operated upon a second case of tumor of the bladder, which had completely recovered from the effects of the operation.—*The Medical Press and Circular*, May 14, 1879.

ANTAGONISTIC AND ANTIDOTAL POWERS OF CHLORAL HYDRATE.—Dr. Husemann found that in rabbits chloral hydrate acted as an antidote to strychnine, to the combination of strychnos bases known in commerce by the name of leucine, and to thebaine, which produces tetanic symptoms, and at the same time diminished sensibility; the chloral controlled the spasms, and, within certain limits, warded off death. On the other hand, when non-lethal doses of chloral hydrate were administered to rabbits poisoned with ammonium chloride, the fatal termination resulted more rapidly than when lethal doses of either ammonium chloride alone or of chloral alone were employed, probably because of the combination of the paralyzing effects of both drugs on the respiratory centre. The spasms excited by the ammonium chloride were, it is true, relieved or even entirely controlled by non-lethal doses of chloral hydrate, but still death ensued.

Dr. Husemann found the antidotal power of chloral hydrate to be much less against codeine than against picrotoxin. The chloral controlled the spasms and saved life when only the minimum fatal dose, or the minimum dose increased by one-half of codeine was administered, but it was unable to do so when double the minimum dose was given. On the other hand, the life of the rabbit could be saved by chloral when even five times the minimum lethal dose of picrotoxin had been administered. Hence it would

be incorrect to assume that because chloral is a powerful antidote to picrotoxin, it is equally so to the other so-called cerebral irritants.

Against calabarine the action of chloral is the same as against codeine; in poisoning by baryta, however, it is not even able to relieve the symptoms, far less to save life. In poisoning by carbolic acid it does not completely control the spasmodic muscular movements, nor is it able to ward off death, even when only the minimum lethal dose of the acid has been administered. On the other hand a combination of lethal or of non-lethal doses of carbolic acid and chloral hydrate causes a more excessive depression of temperature than is observed in acute poisoning by carbolic acid, or by chloral alone.—*Allg. Med. Cent. Zeit.*, March 8th.

OYSTER-SUCKERS' CORNEITIS.—Under this name Dr. McDowell, of Baltimore, describes a peculiar form of ophthalmia which attacks oyster-suckers alone. The disease presents itself as a dense pearly opacity, about the size of a small pin-head, almost perfectly circular shape, and located at or near the centre of the cornea. The outline of the spot is sharply defined, but it is surrounded by an area of hazy infiltration, a line or a line and a half in diameter, which fades off insensibly into clear corneal tissue. The minute, pearl like central opacity looks most deceptively like a small fragment of shell imbedded beneath the epithelial layer. The condition is usually attended by marked circumcorneal scleral injection, photophobia, lachrymation, ciliary neuralgia, etc. The cornea at the point of the dense central opacity, in the vast majority of cases, takes on ulcerative action, but the ulcer rarely spreads to any dangerous extent either in depth or circumference. In a few cases, however, where treatment was too long deferred, Dr. McDowell observed necrosis of the whole central portion of the cornea; in these cases, after a long period of high inflammatory action, the destroyed tissue was replaced by a dense and permanently opaque cicatrix. When seen sufficiently early, the disease can usually be arrested in from three to seven days. All of the acute symptoms will subside in that time, but the opacity disappears very slowly, weeks being always required for the complete resorption of the effused products. The treatment is the same as for the ordinary forms of corneal inflammation and ulceration.

The diagnosis of this affection from a traumatism, is at first very difficult, especially as the patients often assert that "a piece of shell flew into the eye." The appearances are so characteristic, however, that a mistake is not likely to occur after the affection has once been recognized. Dr. McDowell is disposed to attribute the disease to a specific toxic element contained in the slime and dirt which coats the oyster-shell, and which is introduced directly into the eye.—*Virginia Med. Monthly*, Febr.

A TRAINING-SCHOOL FOR NURSES has been established in Washington, D. C. It has a full corps of lecturers, and is otherwise thoroughly organized for its work. There are now nine such schools in the United States; three in New York, three in Boston, one in Philadelphia, one in New Haven, and one in Washington.

MEMORIAL TO THE LATE DR. MURCHISON.—A movement is on foot to raise a memorial to the late Dr. Murchison. St. Thomas's Hospital and the University of Edinburgh are especially promoting it.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 26, 1879.

THE PREVENTION OF YELLOW FEVER.

THE occurrence of cases of yellow fever in the Southwest has called forth the best efforts of the National Health Board to stay its progress and prevent the spread of panic. Ever since the organization of this body its members have been active in gaining all the possible information regarding the origin and spread of yellow fever, particularly in the districts where the disease prevailed last summer. As the result of such investigations the Board has settled upon some general principles of action which are calculated to meet any emergencies which may arise.

Although acting as an advisory body to the different State Boards, it has the power, when the latter fail to act, and when there is recognized danger of an epidemic, to use such means and to resort to such measures as are best calculated to insure the requisite safety. It will also be recollected that with a liberal appropriation at its command it has the facilities for aiding pecuniarily such districts as are unable to help themselves. This gives a force to any recommendations made by the Board which entirely circumvents any question of States' rights, and leaves local health authorities to accept them independently and act accordingly.

The design of the National Board is to give such general directions as may be required, and which, for the most part, embody the mildest restrictions concerning local sanitation and quarantine as seem to be demanded. This is erring on the right side, and while it gives no cause for any show of dissatisfaction from the State authorities, it leaves the latter to exercise any extra power which they may deem to be necessary. Indeed, the execution of the recommendations is left to State officers, all that is necessary being that said officials shall be dutiful and competent.

In regard to the matter of quarantine, the present conclusion appears to be that each seaport town must

have regulations of its own consistent with the character of its trade, the condition of its harbor, and the facilities for carrying out details. As the result of much discussion, the question has very properly, we think, been left in that state. With inland quarantine a proper understanding is not so easy regarding the means to be adopted for its proper establishment. There are so many ways by which such rules can be evaded that, at first sight, any attempt to establish a practical system would appear to be impossible. Still, a good beginning is made in the recent recommendations by the Board regarding railroad travel, the aim being to disinfect the cars and change them as often as possible when used for any long distance on a road.

Except under extraordinary circumstances there is to be no interruption in travel, care being taken only to guard against the spread of the disease from town to town, or among the passengers along the line. Every train leaving an infected town is to be inspected by a competent medical man and a certificate of the results of the same is to be given to the conductor, and also a certificate to each passenger. No fever patients are allowed on any train, and suspicious cases are to be quarantined. The cars and baggage are to be thoroughly disinfected with sulphurous acid gas before the time of departure, and no upholstered cars are to be used unless, after a thorough disinfection, they are exposed to the open air for at least twenty days. At a point not less than five miles from the place of departure, there shall be an entire transfer in the open air of passengers and baggage to other cars, which cars are not to enter an infected district. After a journey of fifty miles from the point of departure another transfer of freight and passengers is made, the cars disinfected, and then returned. Mail matter is to be exposed to a temperature of 250° F. before being sent from these districts. In case an infected place is on the line of a railroad, trains may pass through, but will not be allowed to stop within a mile of the station, at which place passengers with proper inspection certificates may be taken. No train having a certificate of such inspection, and no passenger having a proper certificate that he was free from disease and that his baggage was properly disinfected, shall be interfered with by any municipal or other local systems of quarantine.

It will be seen that while everything is done to prevent the spread of the disease along the lines of railroad travel, the latter is not interrupted and the passengers are subjected to the least possible inconvenience. Again, the regulations have the great advantage of being reasonable, of appealing to the common sense of the travelling public, and of thus insuring their willing co-operation. No possible objection can be urged against the measure, except perhaps on the part of the railroad companies, who may be put to some inconvenience thereby. Still, there is no doubt that they will be willing to accept such conditions of travel,

under the authority of the National Board, rather than run the risk of quarantine by local authorities at any given point along their lines. Herein, by the way, the great utility of a National Board is shown, in that it is competent to reduce inland quarantine to a system which is uniform throughout all the infected districts, and to protect the travelling public from any imposition by local authorities. Its recognized authority also, and the publicity which is given to its recommendations, are such as insure respect, attention, and obedience from all parties concerned. In fact, the public at large is prepared to act upon any reasonable suggestion from any such body having its confidence, and having the means to enforce obedience to regulations. This being the case, it is with peculiar satisfaction that we notice a late recommendation of the Board to the effect that it is of the utmost importance that all towns, whether in suspected districts or not, should be under strict sanitary regulations, and that everything should be done to insure the greatest cleanliness in doors and out. This, whatever we may believe regarding the origin of yellow fever, lies at the bottom of the prevention of all epidemics, and cannot be too strongly or too persistently enforced.

Since going to press with the last number of the RECORD, our best hopes regarding the immediate disappearance of yellow fever from the city of Memphis have been dissipated.

The scourge has reappeared, and quarantine against the city has again been established by most of the prominent cities of the South and South-west. Business, for the most part, has ceased, and those who can, are fleeing for their lives. But there are many doubtless who will find it impossible to escape, and will be compelled to remain exposed to the dreadful disease. For these unfortunate ones we hope nothing will be left undone to afford the greatest possible degree of immunity and relief.

THE NATIONAL BOARD OF HEALTH.

FROM its inception, we have recognized the formation of a National Board of Health as a forward step of great significance in our national care for the public welfare. It is the first extended recognition of the necessity of general sanitary legislation, and of national provision for the nation's health. Every earnest student of sanitary progress in England and on the Continent has recognized how sadly we were wanting in administrative oversight of so great an interest. We have always waited for evils to accumulate, or for the wild route of some epidemic to impress us with the need of guarding against disease. True, various isolated quarantine systems have seemed to take it for granted that all disease is imported, and so have made provisions of guarded expediency. It is a great step to unify methods of quarantine, and to get the admission which the bill for the prevention of contagious diseases formulates,

that the interests of public health are so all-prevailing, that no little question about State rights must dispute jurisdiction. We would as soon think of ceasing effort to put out a fire, because it had got beyond the county line.

The National Board is scarcely able to get wisely and vigorously at work, before the alarm at Memphis brings it face to face with important questions of sanitary administration. Very crude and diverse views as to the powers of the Board exist with those who have not fully grasped its intent.

First of all, it is intended to be largely a gatherer of facts, a recipient of information. It might keep busy a year or more merely in studying the actual state of things all over the country and on the seas, in order to avail itself of facts upon which it can safely predicate advice or action. It must first receive and digest information before it can be expected either to issue complete codes or to be very active in execution.

Next, it is largely an advisory and emergency Board. It does not limit the action of States. It would be a sorry result if city or county turned from self-help, with the idea that here is a power to meet every exigency. It rather presents a motive to every part of the nation to bestir itself for home work in all sanitary care and discipline. We can now easily get wise counsel, expert direction, and be encouraged in a way which gives great moral and social strength. The fact of its existence, and the work it is doing, settles all questions as to the feasibility and necessity of close sanitary care. The character and known ability of its members is a large guarantee that discretionary powers are safely lodged with such a body. All sanitary codes, if good for anything, must delegate large powers, and then hold the authorities as responsible for their discretion as for their legality of methods. This Board is held to the strictest accountability in the use of the moneys confided to it. Exact statements must be made to the Secretary of the Treasury as to the kind of expenditure proposed, and disbursements must be made with the fullest evidence of due service rendered. It is not a great charity fund, upon which with a gush of sympathy all may draw. We take it as a sacred trust for the investigation of facts, for the closest study of causes, and for the watching of the course of disease. If there is to be any permanent benefit therefrom, which shall outlast the peril of an epidemic, we are to see to it that other fountains of charity are not dried up, and that a part of the allowance be dedicated to the closest scrutiny of the causes of various diseases, and the best preventive methods.

Already the Board has shown itself equal to any emergency, and prepared in a proper way to meet any real contingency. The order from the Treasury Department of \$25,000 to Memphis, was not made without placing its expenditure under such definite in-

structions as will make it tell for the limitation of the disease. We are told that from multitudes of sources applications for pecuniary aid from other districts hastened to the national office, and that a sign that no appointments were being made on application had to be posted. Individuals or municipalities may not get all they ask, but with allowances for mistakes consequent to the initiation of any new system, this Board will be found efficient and successful. It has, and well deserves the confidence of the medical profession, and of those laymen of large experience who have studied the methods of sanitary administration. It has now under close surveillance the South and South-west, in its most exposed points. It has its own trusted methods of inspection, and a very large correspondence, so as to ascertain facts with accuracy. It is not improbable that multitudes of infected particles are hidden here and there in many a Southern city, and will record their cases. Nor is it improbable that a faithful cleansing by local authorities just now, before any outbreak, and the readiness of this Board to at once insist upon right measures, will limit the disease just as a fire is limited when not permitted to gain headway. It is real fire, and cannot at once be annihilated; but it can be prevented from attaining the proportions of an epidemic. Thus far we are encouraged. The circulars and the bulletin of the National Board show that it has its studied methods and its plan of campaign laid down. We beg physicians all over the South and West, while not alarmists, to be intensely watchful, and to fully acquaint themselves with all the advisements of this Board, and mayors and council boards to do the same.

Reviews and Notices of Books.

ON DISEASES OF THE ABDOMEN, by S. O. HABERSON, M.D. Second American from Third English edition. Philadelphia: Henry C. Lea. 1879. 8vo, pp. 554.

It is occasionally a relief to take up a work, comprehensive in character, which does fill up valuable space in carrying each disease through the whole course of the world's history. Dr. Habershon has given us such a book, and we have to thank him that we can learn everything about gastric ulcer without being distracted by a story of its probable origin among the Troglodytes and subsequent modification among the Fins. The work is eminently a practical rather than a classical one. It abounds in well-condensed illustrative cases, and its descriptions of diseases are clear and complete. We miss the elaborate classifications and tables of differential diagnosis which are the usual dress of the modern medical work, but we do not know that it is any less serviceable on this account.

One of the best written chapters is that on functional disorders of the stomach. Dyspepsia is divided into five different forms, characterized respectively by derangements in the mucous membrane and gastric juice; in vascular supply; in the nerve supply; in impeded muscular movements; and in fermentation

of the contents of the stomach. Under these various heads all the symptoms of indigestion are drawn, and valuable indications for treatment given.

In the present edition two new cases of gastroto-my have been added, making seventeen in all. The record is not a cheering one, as all the patients soon died, and only two even survived the operation.

Other additions have been made to the book, bringing it well down to date. On the whole, although it does not rise to the dignity of a classic, it forms an extremely useful manual for the ordinary practitioner.

FISTULA, HEMORRHOIDS, PAINFUL ULCER, STRICTURE, PROLAPSUS, AND OTHER DISEASES OF THE RECTUM; THEIR DIAGNOSIS AND TREATMENT. By WILLIAM ALLINGHAM, Fellow of the Royal College of Surgeons of England, Surgeon to St. Mark's Hospital for Fistula and other Diseases of the Rectum, etc., etc., etc. Third Edition, partly re-written. Philadelphia: Lindsay & Blakiston. 1879.

THIS, which may be justly considered the best practical treatise on the diseases of which it treats in the English language, has been most thoroughly re-written. Some of the opinions expressed in former editions have been modified in consonance with the increased experience of the author, who is certainly the most earnest worker in his special department, and his large experience has been brought to bear upon the innovations of the past ten years.

In Chapter IV. the treatment of fistula by elastic ligature is considered. He regards it as valuable in many cases, and frequently invaluable as an auxiliary to the knife, its application inflicting little or no pain, causing no hemorrhage, and peculiarly adapted to sinuses running high up, and such sinuses Mr. Allingham emphatically states should be divided as far as they go. He gives a woodcut of an ingenious contrivance for passing the ligature.

In Chapter VIII. he refers to the views of Verneuil, based on his own and the dissections of Gosselin in 1864, Dubrend and Richard, 1868, and by Duret in 1877, which the French surgeon thinks have proved that the superior hemorrhoidal veins only are connected with the portal system, and solely form internal hemorrhoids, external piles being formed from the external and middle hemorrhoidal, which are connected with the general venous system. These dissections demonstrate that the sup. hemorrhoidal veins, at a height of about four inches, perforate abruptly the muscular coats through "véritables boutonnières musculaires," the contraction of which in abnormal conditions causes stasis and the tumors recognized as internal piles, and on this theory Verneuil bases the now fashionable treatment strongly advocated in France—the treatment by dilatation; our author explains his objections to the views and treatment of his French confrère, and their study will well repay perusal.

In the operative treatment of internal piles, Mr. Allingham objects to the écraseur of Chassaignac, or the wire of Maissonneuve, caustics of all kinds, save the application of nitric acid in exceptional cases, to the application of cautery "ponctué," "linear" or galvanic wire. In reference to the American method by introduction of carbolic acid into the interior of such growths, he says: "I tried the injection plan on some few cases, but the result was much pain, more inflammation than was desirable, a lengthy treatment, and the result doubtful; certainly not a radical cure."

In many cases he asserts dilatation will give wonderful relief; but as often no good results, and his

preference remains for ligature applied, as in the manner so long used by Mr. Salmon.

Chapter XVII. treats of ulceration and stricture of the rectum, and the doctrines are almost exclusively those of the English school. In treating of the etiology of stricture, he devotes considerable space to a review of the opinion first enunciated by Gosselin, and subsequently studied by an equally acute observer on this side of the Atlantic, and placed prominently before American readers in an article on "Venereal Stricture of the Rectum," by Erskine Mason, *American Journal Medical Sciences*, January, 1873. Mr. Allingham does not believe that soft sores are a cause of stricture, and although he fortifies his position by the testimony of such authorities as Mr. Jas. R. Lane, Walter Coulson, and Christopher Heath, we do not think he invalidates the claim that such lesions are at least among the causes of stricture. Of course we are well aware that the new light brought to bear by recent investigators has materially modified the opinions that have prevailed since Gosselin's views were given to the profession; and we believe that pathologists have satisfactorily proved the existence of several causes. We do not refer to obstructions produced by the cicatrization of tuberculous and dysenteric ulcers, but only to those of venereal origin. Tournier speaks of three causes: 1st. Ulcerous syphilides, late secondary and tertiary. 2d. Gummy infiltrations, one case only recorded by Verneuil, none ever observed by Tournier himself. 3d. Syphilôme anorectale, an infiltration of the anorectal walls, the initial structure of which is as yet undetermined, but susceptible of degenerating into a retractile fibrous tissue, and constituting in that way intestinal constrictions of greater or less extent. Duplay likewise speaks of syphilôme anorectale as a production localized in the rectal walls in a manner similar to interstitial syphilitic hepatitis, which results from a specific deposit in the parenchyma of the liver. The cellular tissue is invaded by a neoplasm of syphilitic origin, by gradual infiltration that ends in retraction. He also thinks that the irritation to which the rectum is subjected is the determining cause.

Chapter XVIII., cancer of the rectum, has much new matter in it, with a number of histories of cases of excision.

The remaining chapters are devoted to rodent or lupoid ulcer, and villous growths.

and intestines; in the second, bronchi and lungs, were the sources of high death-rates.

Mortality diminished with every day of advancing life. Every additional hour improved the baby's chances for preservation. Almost one-half of the infants dead before the end of the first year died before they were one month old. Thus the causes of disease were the more active the earlier they were brought to bear upon the young with their defective vitality.

Two grave conclusions were to be drawn from that fact. The first was, that the diminution of early mortality depended on avoiding diseases of the digestive organs by insisting upon normal alimentation. That was principally important in the first few months. While breast-milk had been shown to lower infant mortality through the whole first year, it did so more in the first few months. Thus, though an infant might not be fed on breast-milk through the whole normal period of nursing, a great gain, indeed, was accomplished by insisting on nursing, though for a limited time, perhaps two months only. There were but few mothers but were capable of nursing during that brief time, and none who ought to be spared the accusation of causing ill health or death to her baby if she refused to nurse it at least through the first dangerous months. The second conclusion, resulting from many figures, was that the dietetic problems and rules for the infant concerned the digestive organs mainly, so much so indeed, that infant dietetics and the dietetics of the infant digestive organs appeared nearly identical.

It was true that in this city we met with a high mortality, even in children of more than a year. In fact, public opinion looked for a higher mortality in the second than in the first summer. The fallacy of that assumption could be easily corrected by the statistical reports. The second summer was the period of danger in part only because of the heat of the season, but mainly of the errors in feeding. Conscientious and intelligent families in good circumstances were not apt to lose their infants in their second summer.

Nor was it necessary that he should insist upon the danger incurred by the belief that diarrhœa—a pathological condition—was a normal attendant on and a relief of a physiological process such as dentition. It was certain, that very few, if any, popular beliefs had been more destructive than that an intestinal catarh must be left alone, no matter from what source it originated.

Healthy infants had a normal tendency to loose, liquid, or semifluid evacuations from the bowels. The causes were partly in the condition of the intestinal tract, and partly in the nature of the normal food, viz., breast-milk. The peristaltic movements were very active; the young blood-vessels were very permeable; the transformations of surface cells very rapid; the peripheric nerves very superficial, more so than in the adult, whose mucous membrane and submucous tissue had undergone thickening by both normal development and morbid processes. In the young infant the peripheric ends of the nerves were larger in proportion than in the adult; the anterior horns of the nerve-centres were more developed than the posterior ones. Thus the greater reflex irritability of the young, particularly in regard to intestinal influences, was easily explained. Besides, the action of the sphincter ani was not quite powerful, the feces were not retained in the colon and rectum, and no time was afforded for the reabsorption of the liquid or dissolved constituents of the feces. Moreover, the frequency of acids, sometimes normal, in the small

Reports of Societies.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, May 26, 1879.

DR. A. E. M. PURDY, VICE-PRESIDENT, IN THE CHAIR.

THE TREATMENT OF INFANTILE DIARRHŒA.

DR. A. JACOBI read an important paper on the above subject, of which the following is an abstract:

Of all the deaths in the first year of life forty per cent. in round number were due to diseases of the digestive organs, and half as many to such of the respiratory organs. In the second year the main cause of death changed completely; for of all the forty-five per cent. of deaths taking place in that year, but nine were due to digestive, and thirty-six per cent. to respiratory disorders. Thus in the first year, stomach

intestines gave rise to the formation of alkaline salts with purgative properties.

The nature of breast-milk, even when absolutely normal, was such as to facilitate frequent, large, and fluid evacuations.

FAT.

First, as to its fat where no food was given but mother's milk, *a good deal of fat was eliminated without any change.*

What had been called detritus in the feces was mostly fat, and very probably remnants of intestinal epithelium. Practically that *fact* was of the very greatest importance. The conclusion was, *we were almost certain to give too much fat; it was scarcely ever probable that there was too little.* Therefore the addition of cream was reprehensible, no matter in what shape. Thus in the most normal milk there was more fat than required.

In the first period of lactation the glandular transformation was not yet accomplished. It required days to exhibit casein. At the same time the percentage of butter and salts was very high indeed, both of which explained the *laxative* character of colostrum.

There was no stability in the nature of breast-milk, and very much less in the human than in the animal female, for obvious reasons. Its constituents and effects might even change from hour to hour, from day to day, sometimes it would be milk, sometimes milk with transuded serum.

SUGAR.

Again, as to sugar. It was abnormally plentiful in colostrum, and in some milks, at times, its percentage was lower than normal. In the former it was purgative, in the latter its absence one of the causes of constipation. Thus the addition of a piece of sugar—which need not be milk sugar—to breast-milk was apt to heal constipation in the infant. He dissolved it in the smallest possible quantity of water, say a teaspoonful, and let the baby take it before each nursing.

CASEIN.

Fourthly, as to casein. When present in an abnormally high percentage, it might either constipate or by remaining undigested, and, acting as a local irritant, produce a diarrhœa. In those cases of diarrhœa the stools were mixed with white flocculi, small or large, sometimes in astonishing quantities and for a long period. The treatment of such diarrhœa was by no means very simple, unless the breast-milk was changed. When such a change could not take place, he added oatmeal gruel or barley-water in such a manner, that a few teaspoonfuls of it were administered to the baby before each nursing.

Dr. Jacobi then passed to the examination of some of the articles of food mostly used for the young.

Goat's milk ought to be rejected because of its large percentage of fat.

Cow's milk contained more butter than human milk, and if the latter was not entirely digested, the former would certainly leave even more remnants to encumber the intestinal canal. The reaction of human milk was alkaline, that of cow's milk rarely to the same degree.

But the main difficulty was in the large percentage and in the nature of the casein of cow's milk. The casein of cow's milk and the casein of woman's milk were two different substances. The former had an acid reaction and was soluble in water in the proportion of 1-20. The latter was alkaline or neutral, and almost entirely soluble in water. There was less casein in

woman's milk than in cow's milk. The fact was beyond doubt that pure cow's casein was very much less digestible than human casein.

At all events, no addition we knew of could render cow's casein more digestible than Nature made it, and the only thing which could be obtained by any sort of manipulation of the milk was to make it less injurious. Perhaps, however, the plan upon which Dr. J. Rudsich had acted might recommend itself to the attention of the practitioner. In order to make cow's milk more digestible, he had introduced into Dr. Jacobi's practice a mixture which promised to be of great value in all those cases in which coagulability of the milk was the prominent obstacle to its usefulness. The mixture suggested by him, and used by them up to that time mainly in diseases of adults, such as anæmia, gastric catarrh, ulcer of the stomach, slow convalescence, etc., was the following: to one pint of water add one-half teaspoonful of official dilute muriatic acid. To that mixture add one quart of raw cold milk; mix the two liquids thoroughly and then boil for ten or fifteen minutes. He had found that preparation to be very digestible, and well tolerated by very feeble digestive organs. Valuable as that preparation of cow's milk might prove in future, there was one method for making cow's milk more available, which was at once simple and effective. No cow's milk ought to be administered without the addition of chloride of sodium. Not only cow's milk, but also—and even much more so—farinaceous admixtures to cow's milk required its presence in the food.

PREVENTIVE TREATMENT.

The preventive treatment of diarrhœa, depending on defective alimentation, consisted in so changing and arranging the milk used for babies that the casein would not coagulate in large lumps, and thus become more digestible. That object could be obtained by adding such farinaceous food as did not contain much starch. It consists in diluting the boiled and skimmed milk with barley-water or oatmeal gruel. It must be boiled to check its tendency to become sour, to remove a portion, though small, of its casein and fat, and to expel the gas contained in the raw milk to the amount of three per cent.

Of the two, he preferred barley for general use. [He recommended that the barleycorn which was employed for infant diet should be ground as thoroughly as possible in a coffee-mill, both in order to diminish the period necessary for cooking it, and also in order to retain the gluten. *It was even preferable, for very young infants, to cook the barley whole for hours, thereby to burst the outer layers of cells, empty their contents, and then, by straining, to get rid of the larger part of the starch which was found toward the centre.* There was no danger to which little children were so liable as that which arose from their tendency to diarrhœa. His advice, therefore, was to administer barley to children who manifested a tendency to diarrhœa, and oatmeal to those having a tendency to constipation, and, whenever a change occurred in the intestinal functions, to give one or the other, according as constipation or diarrhœa predominated.

He held that mixture to be the *conditio sine qua non* of the thorough digestion of the milk. It only would insure the proper nourishment of the infant. With that food alone he had seen children endure the heat of summer without any attack of illness whatever. He had occasion again and again to be convinced of the reliability of the mixture. It had the advantage, too, that it necessitated no dependence upon the honesty

or competence of the apothecary or manufacturer, but could be prepared by any one, however poorly situated. Should a slight diarrhoea occur, or a little casein be vomited (a rare accident, to be sure), or casein occur in the stools, then all that was necessary was to diminish the proportion of milk. It might sometimes be necessary, though very seldom, to withdraw the milk entirely for a time, but only in cases of real illness. If the physician or attendants had properly apportioned the ingredients of the mixture, we might be rather sure that the child's digestion and assimilation would be regular and normal. Infants that were partly nourished at the breast almost invariably thrived well with the addition of his mixture. Children, from their fourth or fifth month and upward, might often be fed with it exclusively, and not unfrequently nothing else was given from the day of the birth.

The addition of barley or oatmeal for the purpose of rendering milk digestible was not, however, absolutely indispensable, though he had learned to prefer them. For, gum-arabic and gelatine were also very valuable ingredients, indeed, of infant foods. Dr. Jacobi then dwelt at some length upon the changes which gum-arabic and gelatine undergo when put into the stomach.

CURATIVE TREATMENT.

The amount of food should not be larger than we had reason to expect could be easily digested. At all events, either lengthen the intervals between the meals or reduce the quantity of food given at one time, or both. When diarrhoea made its appearance in infants who had been weaned, it was desirable to return them to the breast. Those who never had breast-milk might be given the breast if they could be induced to take it, but only rarely would that be found possible. Whenever a child at the breast was taken with diarrhoea, the passages from the bowels should be studied as to their contents. If a certain amount of curd was found in them, the least that was to be done was to mix the breast-milk with barley-water. That might be done in such a manner that, each time before nursing, one or two teaspoonfuls of barley-water was given the child, so that the farinaceous food and the breast-milk mixed in the stomach. Or, it might be found advisable to alternate breast-milk and barley-water. In bad cases, particularly when the milk was found to be white and heavy, and contained a great deal of casein, it would be found necessary to deprive the child *altogether* of its usual food. In such cases, the child would do better on barley-water alone (that to be continued for one or two days), than to expose it to the injury which would certainly follow the continuation of the casein food.

When diarrhoea occurred in children who had been fed alone upon cow's milk, unmixed or mixed, it was necessary to reduce the quantity of cow's milk in the mixture. As a rule, we had to remember that cow's milk alone was apt to produce diarrhoea, and it should be considered as a maxim that, whenever diarrhoea made its appearance, the amount of cow's milk given to the child should be reduced. When a mere reduction of the quantity did not suffice, it was very much better to deprive the child of milk food altogether. Not infrequently the removal of milk from the bill of fare was the only thing which would restore the child to health. It was possible that a mixture, such as recommended by Dr. Rudish, already mentioned, would be found digestible, even in such cases. In many cases, as a dietetic measure, it would be found advisable to add one or two tablespoonfuls of lime-water

to each bottle of food with which the child was supplied.

In those cases in which barley-water did not seem to suffice as a nutriment, or where it would be dangerous to allow children to lose strength, a mixture which he had used to great advantage was the following: Mix the white of one egg with four or six ounces of barley-water, and add a small quantity of table salt and sugar, just sufficient to make the mixture palatable. The child could take this either in large or small quantities, according to the case.

In those cases in which the stomach was irritable, and vomiting had occurred, it was now and then better to give a small quantity, even one or two teaspoonfuls, and repeat the dose every ten, fifteen, or twenty minutes, than to give larger quantities at longer intervals.

In those cases in which the strength of the child has suffered greatly, he recommended the addition of brandy to the mixture in such quantity that the child would take from one drachm to one ounce (grms. 4.0 to 30.0), more or less, in the course of twenty-four hours.

In those extreme cases in which the intestinal catarrh was complicated with gastric catarrh, where the passages were numerous and copious, and vomiting constant, where both medicines and food were rejected, there was frequently but one way to save the patients, and that was to deprive them *absolutely* of everything in the form of either drink or food or medicine. It was true that such babies would suffer greatly from thirst for an hour or two, but it was a fact that, after two or three hours, those children would look better than before the abstemious treatment was commenced. Not infrequently four or five hours of total abstinence would suffice to quiet the stomach and diminish both the secretion and the peristaltic movement of the intestinal tract. In some cases *six* or *eight* hours of complete abstinence would be required; or such children might be starved for even *twelve* or *sixteen* hours, with final good results. The first meals afterward must be quite small, and they would be retained, and, as a rule, such children would subsequently do well.

Dr. Jacobi here enforced the necessity of supplying the patient with as much cool fresh air as possible. The worst out-door air, was better than close in-door air. If possible, the children should be sent immediately to the country and into the mountain air.

The *second* indication consisted in the removal of undigested masses retained in the intestinal tract. Not only in cases in which the diarrhoea had resulted from previous errors in diet of the child, but also in those cases dependent upon sudden changes of temperature and exposure, it was desirable to empty the intestinal tract. For that purpose castor-oil, calcined magnesia, or calomel might be used.

Third. Nothing should be given that contained salts in any sort of concentration. Thus, beef-tea should be avoided. It must be remembered that that form of meat-extract contained a very large amount of salts, and that the direct effect of those upon the intestinal canal might be productive of very unpleasant consequences. If the people insisted upon giving it, and there was no special contraindication to its use in a given case, it should be administered only in connection with some well-cooked farinaceous vehicle, and the best of all for that purpose was barley-water; or it might be mixed with beaten white of egg, but no more chloride sodium should be added. For the main danger in beef-tea was the concentrated form in which its salts were given.

Fourth. Everything should be avoided that in-

creased peristaltic motion. Thus, carbonic acid and ice internally.

Fifth. Avoid whatever threatened to increase the amount of acid in the stomach and intestinal tract. There was so much acid in the normal, and still more in the abnormal stomach and intestinal tract, that it was absolutely necessary to neutralize it. For that purpose it was safer to resort to preparations of calcium than of sodium or magnesium. So far as lime-water was concerned, its administration, certainly, was correct chemically. But we should not place too much reliance upon that popular remedy. We should not forget that it contained about one part of lime to eight hundred of water, and that it was necessary to swallow at least two ounces of the fluid in order to obtain a single grain of lime.

A further indication was, the necessity of destroying ferments. For that purpose most metallic preparations would do fair service. One which had been extensively used, was *calomel*, and now in small doses frequently repeated— $\frac{1}{10}$, $\frac{1}{8}$, or $\frac{1}{4}$ a grain [0.1 0.15 0.03] every two or three hours. As to its effect as an antifermentative, there could be no doubt.

Nitrate of silver, when given for the same purpose, should be largely diluted. From $\frac{1}{10}$ to $\frac{1}{16}$ of a grain [0.0015 0.004], dissolved in a teaspoonful or tablespoonful of water, might be given every two or three hours, and not infrequently with fair result. That was especially important with regard to injections of nitrate of silver into the rectum, where it was apt to do as much harm as good. Whenever it was to be given in that way, the solution should be mild and largely diluted, or the anus and its neighborhood should be washed with salt water before the injection was administered.

Bismuth acted very favorably. Moderate cases of diarrhoea would usually show its effect very soon. Doses of from $\frac{1}{2}$ to 2 or 3 grains [0.03 0.20], given every two or three hours, would act very favorably indeed. In those cases in which the diarrhoea had lasted for a long time, the doses of bismuth should be large in order to be certain of immediate contact of the drug with the sore surface.

A final indication was the depression of the hyperaesthesia of the general system and of the intestinal tract in particular. There had been authors who condemned the use of opium altogether, which, certainly, was incorrect. The doses should be small, and they might be repeated frequently. Administered in that manner, opium could be used with perfect safety both internally and in an enema. One of the rules for giving opium was that the child should not be waked up for the purpose of taking the medicine. Whenever there was fear of collapse, it was safer to give $\frac{1}{200}$ of a grain (0.0003) every half hour or hour, than to administer $\frac{1}{50}$ of a grain (0.0012) every two hours.

Alcohol.—Small and frequent doses would certainly stimulate the nervous system, digestion, and circulation, and they also stimulated the skin and increased perspiration. Alcohol, given in that manner, certainly arrested fermentation. Moreover, it took the place of food, and acted favorably as food when no solid carbohydrates were tolerated by the intestinal tract. As it was absorbed in the stomach, so did it protect the intestinal tract.

Finally, it is necessary to reduce the amount of secretion taking place from the surface of the intestinal tract. For that purpose astringents might be used, such as alum, lead, tannic acid, permanganate of iron, and, what had already been spoken of, nitrate of silver. In all those cases in which the stomach participated in the process to any considerable extent, almost any astringent would prove ineffective. To

fulfil several indications at the same time, it was often good practice to combine remedies.

The main indications were to neutralize acids, to reduce nervous irritability, to arrest secretion, and to change the condition of the surface of the catarrhal mucous membrane.

For that purpose, in the generality of cases, he combined bismuth, opium, and chalk, according to the following formula:

℞. Bismuth subnit. gr. i. (0.05)
Prepared chalk. grs. ij. (0.10-0.20)
Dover's powder. gr. $\frac{1}{2}$ (0.02)

That combination was suitable for a baby ten or twelve months of age, and the dose could be repeated every two hours. In all those cases in which acid was very abundant, it was necessary to increase the doses of antacids without necessarily giving large doses of opium.

Hot bathing was especially serviceable in those cases in which the surface was cool and the temperature of the body, measured in the rectum, was pretty high. To relieve intestinal pain, plain warm fomentations; to relieve heat, cold applications were sufficient.

Camphor stimulated the heart, and reduced temperature, and might be used internally or subcutaneously according to the necessities in the case. For subcutaneous injections it might be dissolved in either oil or alcohol. The effect derived from camphor as a stimulant was not permanent, but very much more so than that produced by carbonate of ammonia. The dose might be from $\frac{1}{4}$ to $\frac{1}{2}$ a grain [0.015 0.03] every hour or two, when only a moderate stimulation was required. In urgent cases it might be given in doses of from five to ten grains in the course of an hour, and usually the effect would be favorable. It was, however, only in cases in which real collapse was present that doses of five or ten grains would be required.

There was no remedy that would act more favorably in conditions of great debility and collapse than *musk*. It might be given in doses of five or ten grains, and repeated every half-hour or hour. More than two or three such doses would not be required to yield a result.

The paper being before the Society for discussion,]

DR. WILLIAM H. THOMSON remarked that, doubtless, each one of us had, by experience and reflection upon that experience, been led to the conclusion that in the course of years we became more or less a law to ourselves. He was very glad that the opportunity had been afforded for some one to come in contact with his own ideas, and none more acceptably than the author of the paper, who was one of the most eminent authorities in his department in this county. In certain respects he disagreed with Dr. Jacobi, and was sure that he dreaded the beginning of dentition, as having a direct bearing upon the etiology of some of the more serious forms of summer diarrhoea, which occasionally occurred with the suddenness and explosiveness of true cholera. The reflex effect from the irritation incident to dentition was to suspend the secretion of gastric juice, hence he had been led to administer bromide of potassium early in the treatment of infantile diarrhoea, and, as he thought, with good results. He employed it as an agent that arrested reflex irritation. He had been led to believe there was a difference between the diarrhoea due to local irritation, such as teething or fermentation of the contents of the intestines, and the diarrhoea which seemed to be due to sudden nervous paralysis. The one he would regard as a catarrhal diarrhoea, and the other

as a true choleraic diarrhœa. It had appeared to him that there was a difference between the two classes of cases from the very beginning. The manner in which the choleraic diarrhœa began—without any evidence of distress accompanying or preceding the discharges, but the existence of large watery passages and their sudden development of grave cerebral symptoms,—had led him to regard its access as very often due to an infection of a kind not dissimilar to Asiatic cholera. It was in the choleraic class of cases in which the effect of camphor seemed to be beneficial, and to be indicated from the very commencement. He always ordered camphor or some remedy allied to camphor in any case of diarrhœa in which there is much looseness of the bowels without pain, and he directed special attention to that point, to be noticed by the attendants upon children in warm weather. Camphor, unquestionably, was a substance which was not dissimilar to carbolic acid and the whole array of spices, which were antiseptics when taken internally. He relied very much upon them. The action of spices was very similar to the action of camphor, and in some cases peppermint and allspice were combined with small doses of camphor, preferably in those cases in which there was great irritability of the stomach.

Lastly, as to the question of the use of hot water for the purpose of restoring the circulation in cases of threatened collapse, he fully agreed with Dr. Jacobi in the employment of the agent for that purpose, for he had used it with great success to overcome sudden and exceedingly dangerous contraction of the peripheral arteries. He used large hot-water injections, and ordered them to be given as freely as possible. He thought the hot water acted in two ways: 1. It aroused the patient; and 2. It allayed the peristaltic action of the intestines. For dysentery he gave but little medicine, but constantly washed out the lower bowel with hot-water injections. Finding that it was equally well borne in the dysentery of children as adults, and allayed the irritability of chronic dysentery, he tried it also in cholera infantum, and strongly recommended its use.

The Society then adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 14, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

WAXY DEGENERATION OF THE PLACENTA.

DR. C. HEITZMANN presented microscopic specimens prepared from six placenta, which exhibited a change in placental tissue heretofore undescribed. In all the cases premature birth had taken place; the earliest at the fifth and the latest at the eighth month of uterogestation. To the naked eye, the placenta exhibited grayish or yellowish patches scattered through the solid part, the decidua, and less marked through the villous portion.

In all the cases the diagnosis of fatty degeneration of the placenta had been made, and Dr. H. was of the same opinion when he first saw the specimens. In all, the size of the placenta was normal, corresponding to the month of pregnancy. In all, the fetus was well developed.

In some of the cases the fetus was dead at the time of its birth, and in those in which the child was born alive it died shortly after, breathing only a few times.

In no instance was there any clinical history of syphilis.

In a number of the cases the premature birth occurred in apparently perfectly healthy women.

The first specimen was a placenta that was presented to the New York Pathological Society by Dr. Salvatore Caro, as an illustration of fatty degeneration, and taken from a woman who had had a succession of premature births dependent upon that cause.

Dr. HEITZMANN had examined the specimen many times, and had failed each time to find any microscopic evidence of fatty degeneration, although the gross appearance was such as indicated its presence. The specimen had been preserved in chromic acid, a fluid not unfavorable to the perfect preservation of fatty tissue, and yet he had not been able to discover anything which he could call fatty degeneration. On the contrary, the microscope revealed a change that had not heretofore been described as existing in the placenta. There was found a peculiar homogeneous, shining material, which took carmine, was slightly stained with chloride of gold, and presented the ordinary appearance of waxy degeneration. There were no protoplasmic bodies present. In the villous portion the same change existed, but to a less marked degree. A large number of the capillaries were lost, being transposed into the same material. The myxomatous tissue of the placenta was missing altogether in the portions affected. This change Dr. Heitzmann had found in six specimens of so-called fatty degeneration of the placenta, and the question arose in his mind, Was there any such thing as fatty degeneration of the placenta? Was not the change, which had been regarded as fatty, a waxy degeneration?

In one case the fetus was examined, and no evidence of waxy degeneration could be found.

The report was presented as a provisional one.

DR. C. C. LEE asked Dr. Heitzmann if he was able, from his researches, to suggest any therapeutical measures to prevent the change described?

DR. HEITZMANN replied that so long as we did not know what the essential chemical change was, we could not expect to reach any conclusion regarding its therapeutics. The microscope thus far had given but few practical facts with regard to therapeutics.

DR. J. C. PETERS referred to the fibrin-destroying function of the liver, and suggested it might be barely possible that, in those cases in which syphilitic contamination was not present, attention might be directed to that organ.

DR. HEITZMANN thought that fibrin did not have much to do with the change known as waxy degeneration.

DR. J. W. HOWE believed it fair to assume that other observers were correct in reference to what they had determined to be fatty degeneration of the placenta.

CYSTITIS—SUPPURATIVE NEPHRITIS—PERINEPHRITIC ABSCESS—ACUTE PERITONITIS.

DR. C. C. LEE presented the urinary organs removed from a woman who died from acute peritonitis following perinephritic abscess, which in turn followed pyelitis and cystotomy:

S. J., æt. 36, born in London, widow, had been ill for eighteen months with symptoms of cystitis. She had previously been treated for Bright's disease and antelexion of the uterus. At times she had passed a large amount of pus with urine, which, at other times, was quite clear. No uræmic symptoms had ever occurred. She was admitted to the Woman's Hospital October 24, 1878. A long course of treatment for her cystitis produced no benefit, and February last she was transferred from Dr. Emmet's

service to Dr. Lee's. At that time her bladder was contracted and so irritable as to hold only an ounce of urine. As all her previous treatment had failed to relieve it, he performed cystotomy February 12th, keeping the opening patent with a glass tube. In ten days the bladder symptoms improved greatly, but sweating, high temperature, and chills began to appear and recurred regularly. Quinine was used freely without benefit. The tube was removed on March 21st. In ten days from that date pain appeared in left renal region, and in two days this was followed by a circumscribed swelling, which indistinctly fluctuated. It was aspirated and pus was obtained. Aspirated twice again, and finally opened freely under spray; abscess washed out daily; drainage-tube kept in; but the patient slowly sank, and died April 24, 1879.

Autopsy twenty-four hours after death. — Body emaciated. There was an incision about two centimetres in length in left lumbar region, five centimetres above the middle of the crest of the ilium. That incision extended through the abdominal walls into an abscess seated on the anterior face of the left kidney. That abscess had opened into the peritoneal cavity, so that a probe could be passed from the external opening directly into the peritoneal cavity, the internal opening being nearly opposite the external, being situated to the left of the descending colon, three centimetres above the crest of the ilium. The accumulation of pus in the abdominal cavity, which communicated with the perinephritic abscess, was encapsulated by recent adhesions between the intestines and the abdominal walls in the left lumbar and iliac regions. There were about eight ounces of pus thus shut in. There was also a moderate amount of general peritonitis, evidenced by recent fibrin on the visceral and parietal peritoneum. There was a small abscess in Douglas's cul-de-sac about the size of a pigeon's egg, situated on the right side and encapsulated by recent adhesions.

Heart normal; decolorized post-mortem clot in right ventricle.

Pleura: Extensive old pleuritic adhesions on right side. Lungs normal.

Spleen normal.

Kidneys: The *left* kidney was changed into a sacculated mass; the cavities were filled with pus; numerous small abscesses were in the septa which separate the larger cavities; the pelvis was not dilated; on the other hand, it appeared contracted, and its mucous membrane thickened and coated with pus. There seemed to be no kidney parenchyma left; the capsule was thickened; there was a sloughy abscess in the connective tissue outside of the kidney, especially on the anterior surface; the perinephritic abscess was surrounded with indurated tissue, and, as above described, communicated both with the external incision and with the peritoneal cavity. The kidney measured twelve centimetres in length. The left ureter was somewhat dilated, but more noticeably its walls were greatly thickened and very dense. The *right* kidney was enlarged, and presented on its surface and cut section numerous small, yellowish-white streaks and nodules (beginning of acute interstitial nephritis). The pelvis was injected. The ureter was normal.

Bladder: It was contracted, and contained about a teaspoonful of muco-pus; the mucous membrane was of a dark slate-color, with a patch of livid injection on the posterior surface, corresponding to where the cervix of the retroverted uterus had impinged against it. The walls of the bladder were of normal thick-

ness. The openings of the ureters were free and normal. There was a fistulous communication between the posterior surface of the bladder and the vagina on its anterior wall.

Uterus: The uterus was retroverted, and bound down by adhesions of moderate firmness. The posterior lip of the os externum was split, and one portion projected, as a polypoid excrescence, into the vagina. The mucous membrane was smooth and normal. The uterus and vagina were in other respects normal.

The *ovaries, rectum, and liver* were normal.

Stomach: It presented a stellate fibrous cicatrix on its anterior surface.

Intestines normal.

DR. LEE remarked that he presented this specimen simply because of its surgical interest. It was the only case of cystitis on which he had operated, knowing the patient to be the subject of Bright's disease. He believed the obstinate cystitis justified the operation under the circumstances.

(To be continued.)

ALCOHOLIC INEBRIETY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In almost every medical journal, both English and American, as well as continuously in the secular press of both countries, inebriety is becoming discussed as the crying evil and curse of the day. Medical societies and religious organizations over both countries have earnestly deliberated and pondered over various plans to check it, well-meaning and zealous temperance lecturers have traversed both sides of the ocean, and fanatical women have in some cases banded together under the name of crusaders, and brought their might to bear down upon it, and still the evil seems to increase instead of diminishing. Vendors of alcoholic drinks have been burdened with heavy taxes, and in many cases their houses closed either by local law or mob force, and still the number of inebriates is surely on the increase. To condemn none of these efforts is my intention. They are all commendable, or at least the object had in view is commendable. I do propose, though, to say that they have all failed to devise a plan to check it, and the object of this short paper is to suggest a plan I have long thought the only effectual one.

When a man or woman is charged with lunacy, the law provides that a jury be called and proper investigation and inquiry be made as to the mental sanity or insanity, and if the jury adjudge the party a lunatic or insane, he or she is committed to an asylum *volens volens*, and until the superintendent of said asylum declares the patient restored and of sound mind, the law takes from him or her all right of contract or rights of purchase or conveyance.

Is not an habitual inebriate an insane person? Is he capable of thinking or acting for himself or those who are dependent upon him? If he is insane—incapable of transacting or performing the duties he owes to himself, his family, his friends, or his community—should not he and his family and friends, and the community in which he lives, have the same protection by law as if he were insane from any other cause? It seems but fair that they should. Then what are the laws to be enacted? Simply these: Let each

State make laws levying a special tax on every manufacturer and vendor of intoxicating liquors; let the fund thus created be appropriated solely to the erection, support, and maintenance of as many inebriate asylums as may be necessary, and then, in every case of habitual drunkenness or inebriation, let the law be made to apply as in any other case of insanity. Let a jury of inquiry be called, and if, upon careful investigation, the charge be fully sustained, let the party charged or investigated be so adjudged and committed, divested of all the rights taken from any other lunatic, until the superintendent or expert under whose care he has been placed shall decide that he has been sobered and become rational. Then when informed of the action of the strong arm of the law in taking from him his power to purchase or convey any property, he will be brought to a realization of his responsibility or irresponsibility, and thus, I believe, more effectually be broken of the habit.

It may be urged against these views that they are too radical, or that the burden of taxation falls too exclusively on men in one line of business. The first may, at first glance or thought, be true. The second is in no way true, for the tax comes upon the inebriate and not on the vendor. It may also be supposed that these thoughts originate in the mind of a total abstinence man, a teetotaler, or a *Murphyite*. Not so. I recognize the very great value of alcoholic and malt liquors when not abused, and would scarce know how to do a general practice of medicine without their use in many cases.

Expecting that many objections will be raised to these views, and recognizing myself some of them, I am prepared to hear them. And having heard them, I will only ask those objecting to name a more feasible or effective plan.

Very truly and respectfully,

J. M. KELLER, M.D.

HOT SPRINGS, ARKANSAS, JUNE 17, 1879.

DOES SUCCESSFUL VACCINATION PROVE THAT SMALL-POX HAS NOT BEEN RECENTLY EXPERIENCED?

REPLY TO DR. C. IRVING FISHER.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Several months since, while I was sitting at breakfast, I was called into my office, and found there a stranger, divested of his coat, and with the shirt-sleeve rolled up one arm. As I entered he saluted me thus, pointing to his bare arm: "Is that a good vaccination?" After examining his "arm," thinking he was one of those too numerous nuisances who amuse themselves by threatening unfortunate sons of Esculapius with the terrors of the law for using "dirty poek," I said: "I don't know why you ask; but I have no objection to telling you that it is, not only a good, but a remarkably successful vaccination, done some three weeks since, and with virus which probably came from this office, or if not, with virus derived from what was originally supplied by my son or myself; you could not have had so perfect a result if ever vaccinated before, unless in very early infancy." I need not describe the appearance of his arm. On it were (I think two) perfect, typically accurate vaccine crusts. He went on to tell me that he had been treated, in a country town, as a subject of small-pox within five weeks or so, had been subjected to great hardship and to humiliation, such as any one who has had the misfortune to have, or to be

suspected of having small-pox, in a New England village can alone appreciate. After regaining his liberty, he was led to suppose that he had not had small-pox at all, and had been vaccinated as a test. He said that he was shunned by every one in his neighborhood; that people, his friends, ran away from him, and yelled to their children to keep out of his way; and, to crown all, his former employer refused to take him again into his "shop," saying that if he should, he would not have another man in it in five minutes. If I had not had an exceptionally large experience in this sort of thing, I should have supposed the man a lunatic, or that I had been hearing of heathendom in the dark ages, of the realms of Mumbo Jumbo in the days of Prester John; but I knew too well that all the man told me, from his condemnation on suspicion of variolous criminality, to the last unkindest cut of refusal of employment, was, if not *vrai*, at least *vraisemblable*. He asked me to give him a certificate that he had not had the small-pox. This I told him I could not do; that he might have had the disease at some remote period. Although the perfection of his vaccination rendered this unlikely, it was nevertheless possible. I told him I would give him a certificate that he had not had small-pox during the previous few (I think five) weeks. This I consented, nay, possibly volunteered to do, for the sole reason that it seemed possible that such a document might serve to rehabilitate him as a human being, assuage the terror of his fellow-citizens, and restore the poor fellow to a possibility of earning his bread. This certificate was by no means justified in my mind by the success of his vaccination *alone*. Though that was, under the circumstances, an important piece of evidence, it was not the only, hardly the chief one. My opinion was based on the man's quite coherent and consistent narrative of his case and its symptoms, the success of his vaccination, and the total absence, within a very few weeks after the commencement of an attack of small-pox, with considerable eruption, of all traces whatever on the entire cutaneous surface.

It occurred to me, when yesterday quite accidentally reading the note of Dr. Fisher in your issue of June 14th, that I might possibly be the "member of the Massachusetts Medical Society" who "very kindly (?)" advised a lawsuit, etc., etc. There can hardly be a doubt of it, although I am not *absolutely* sure, for I did not ascertain or try to ascertain the name of the doctor, or where he resided. The man, after he got the certificate, said something about instituting a suit, and tried to get me to approve it. I not only did not do this, but strongly advised him to try to get back to his work, and let the law alone; and this I did without any regard to the justice of his cause, but on the ground of the "law's delay," uncertainty, and expensiveness, and the probability that the proposed defendant, being a regular physician, had no funds to satisfy a verdict in damages, even if the plaintiff should obtain one. I wish most pointedly to state, however, that I gave this advice because I always give it in such cases, and not because the doctor was a possible member of the Massachusetts Medical Society.

I do not consider it one of my duties as member of that society to lie to shield a brother member from the consequences of his malpractice, nor do I consider it entirely established that members of the Massachusetts Medical Society are, *ipso facto*, incapable of gross ignorance and malpractice. I know better. Not to go beyond small-pox, I knew an instance in which a prominent member of that old and illustrious association condemned to malignant and

confluent small-pox and the Bridgewater almshouse a young fellow with a gonorrhœa, who, in doctoring himself out of that, had doctored himself into the most magnificent case I ever saw of the peculiar eruption (without fever, headache, or anything else like variola) which follows the continued use of large doses of copaiba. I rescued him as he was being taken to the cart which was to convey him to Bridgewater, and in two days he was at work as usual. Another, who sent to the "pest-house" a case of scabies, and absolutely (not to be taken in a second time) himself took small-pox, with which he was marked for the rest of his life, from a patient with the disease whom he was attending and treating for the itch. Another, who allowed the numerous friends of a patient with supposed varicella to visit him freely, and, when one or two of them came down, they too were chicken-pox. It was not till quite an endemic of variola occurred, and some died, and some got into other doctors' hands, that the member of the Massachusetts Medical Society admitted that the variella was unprecedentedly severe, and presented peculiar and curious features, unlike the usual "plan of creation" in such cases. This will do; but how many of us have known of neighborhood small-pox scares whose only foundation was in variella and measles? I sincerely hope that Dr. Fisher's fears may prove groundless, and that the case will not go into court; but if it does, and I am not mistaken in supposing that he and I are writing about the same thing, and I should be summoned, I shall certainly not perjure myself for his sake, though all the thunders of that Olympus of the Massachusetts Medical Society, the counsellors thereof, should be launched on my devoted head for refusing to do so.

Dr. Fisher's query affords a grand opportunity for the ventilation of such cheap erudition as is readily accessible in any good hand-book of vaccination (say Seaton's). I will not indulge in that way at present, but from my own pretty large experience in the vaccination of soldiers and other adults said or known to have had small-pox previously, glean a few items. Although most of these failed to evince any susceptibility to the vaccine disease, there were still many who proved thus susceptible. Those in whom vaccination "took," however, were adults, and, generally, adults approaching middle age, who had passed through small-pox in infancy or at very remote periods of early life. I think there is ample evidence within my own experience to prove that, if an infant has small-pox and survives till full adult life, he is then as susceptible to a second attack or to vaccination with original cow-pox virus, or the as vigorous and effective lymph obtained by the proper transmission of original cow-pox on a series of bovines as if, instead of small-pox in infancy, he had then been vaccinated with either of those vigorous and perfect "strains" of virus. That there is not such ample evidence of this as of the success of revaccination with vigorous lymph, is because, while every child that is vaccinated (notwithstanding the doleful and prodigious mortality of the anti-vaccine fools) survives the operation, recovery from small-pox in infancy (under two years) is a very rare thing. During the great variolous pandemic of 1872-3 (what a mortality would then have been *sans* vaccination!! It is not too much to say, beyond any within authentic historical record) my office was thronged, for several months, with people to be vaccinated. One day the office door opened and in walked the very worst and most pitiful small-pox wreck that I ever saw,—a woman of fifty and over, who had lost

one eye, and whose face was not a face but a cicatrix. "Oh!" said I, "are you come to be vaccinated too?" I was ashamed of the smile which, quite involuntarily moved my features, when she quietly answered, "yes; that she had had small-pox, as I could see, but it was when she was under a year old, and her reading and her own judgment had led her to believe that she might be again susceptible to the disease, and, as I might suppose, she dreaded it." I vaccinated her and she had an "arm" as perfect as any fine primary vaccination, which indeed it was, for she had never been vaccinated before. This case was only apparently more marked than on a patient in whom small-pox had not left such dire traces because the patient was more so, but it was very striking. I had several cases, in the army, of successful vaccination of men marked with small-pox, but always by an attack at remote periods of early life. Of such cases Dr. Fisher will doubtless easily obtain accounts from his *confrères* and find them in the prodigious literature of small-pox and vaccination, where, with diligence, he may find almost anything; but he will probably find it difficult to procure many *authentic* narratives of cases in which a vaccinated or unvaccinated patient, having just passed *through* and *quite ended* with a case of small-pox or varioloid, proves susceptible to the vaccine disease in a very perfect form. If he succeeds in *thoroughly* and *undoubtedly* establishing his own case, he will make what is not often done nowadays, a really valuable addition to the literature of vaccination.

THE MECHANICS OF LATERAL CURVATURE OF THE SPINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In an important and valuable essay on Pott's disease, recently reviewed in your columns (July 12th, pp. 39, 40), there is an erroneous reference on page 34 to some work done by me several years ago in the study of lateral curvature of the spine. I would like to state that the preparation referred to as moving in obedience to checks and springs was constructed to show that rotation is mechanically an inevitable incident of lateral curvature, and not to explain the etiology of the disease.

It was argued in brief that, as the posterior portion of the column is a component part of the parietes, while the anterior portion is free to move laterally, a lateral curve of the column would be necessarily attended with more displacement laterally of the anterior than of the posterior portion, the motion thus produced being rotation.

This view was thought at the time to be new. Its novelty and correctness have not, so far as I am aware, been gainsaid.

Yours, etc.,

A. B. JUDSON, M.D.

NEW YORK, July 15, 1879.

AN ORDER FOR NURSES.—Queen Victoria has instituted the order of St. Katherine as a reward of merit for those nurses who have distinguished themselves by long service and good conduct. They receive a badge of the Order and an annuity of \$250 for three years. Three nurses have already been decorated.—*British Medical Journal*.

Obituary.

GEORGE HEATON, M.D.

IN the city of Boston, on the first of the present month, died Dr. George Heaton, a graduate in medicine at the University of Pennsylvania, 1840, and member of the Massachusetts Medical Society since 1842, a citizen of credit, a man of the sincerest principles of honor, and a physician whose attainments in the practice of an arduous profession were of a high and thorough standard. Unassuming in his deportment, both among and outside the profession, reticent to a degree that always marks the man of earnest calibre, liberal in his views as to the various doctrines that inculcate the masses of humanity, Dr. Heaton filled a place in the community that needs no lasting monument to denote the loss his death occasioned beyond the very attributes of moral and professional standing that this paragraph refers to. Not only to those who were contemporary with him in the service that he followed, but to the citizens of the commonwealth whose adopted son and useful citizen he was, and to suffering humanity who have, by the brilliant exploits of his genius, the direct sympathy of his professional presence, and the explorations of his master mind, reaped health—the one great boon on earth above all others—must any allusion to his career possess more than an ordinary amount of interest.

Dr. Heaton was born in Alton, Illinois, on the nineteenth of April, 1808. Of his earlier days, his schooling and preparation for the profession he had chosen, we have but little knowledge, nor is it essential to the brief allusion to one or two incidents in his career that are intended. In 1840, or immediately about that period, he was physician to the prison at St. Louis, and at that time is dated a discovery which marked an epoch in the life of the physician whose researches brought forth such light, and an era in the history of surgery that ranks high among the blessings of the practice in any age. This was the discovery of the radical cure of rupture, or hernia, reducible and irreducible, and also for the cure of varicocele and hydrocele. What greater favor in the world could be vouchsafed the human family, who, to a degree, far in excess of any other proportion of ills, are victims to a malady so trying to the hopes of those who suffer, and so exhausting to the patience of those whose skill heretofore had so often failed to make the right provision for a remedy? This discovery was the stepping-stone to a career of high professional fame for the inventor of a process, now given to the world; and right here commenced a series of incidents in his career, of which many must have a vivid recollection.

Soon after the proper test had been made of the efficiency of the process, Dr. Heaton, leaving the West, came to Boston, and commenced the practice of medicine in this city, celebrated for the high attainments of its professional men of *all* arts, as well as for the special high order of all the thinking men who have prominence in any range of life. Flushed with youthful pride at what he naturally and justly thought to be a complete revolution of practice upon this great human malady, Dr. Heaton moved immediately to bring out his operation more fairly to the medical profession. There are those who will no doubt remember that he was not much more than courteously received in his first advances to the

gentlemen of the profession. The work that he described was so simple, so painless in comparison with the older methods, and so perfectly and concisely stated, that the practitioners here were incredulous than an operation so trifling should be so effective as he described it. Those whom he had invited to attend and witness its performance did not consider it worthy of their attention, and with some coolness of manner did not hesitate to show such appreciation, and this, also, in view of the fact that it had already become known that the inventor had effected radical cures on a number of patients. Not disconcerted in the least, Dr. Heaton went to London, taking with him the *secret* of his invention, determined, in view of the treatment he had received, to give it to the old world, and let it reach the new, if it did, without either his assistance or his favor in any degree beyond his own practice. The operation for hernia was presented to the profession in London, who received it with great cordiality. Dr. Heaton was at once launched upon the topmost round of the ladder of professional skill. His acquirements were readily recognized, and his fame spread in proportion to its great desert. The hospitals of London and Paris were the scenes of his very frequent attendance, and operations were also successfully performed, not only upon the private patients of other physicians, but upon several of the nobility. He soon became a Fellow of the Royal Chirurgical Society of London, of the Westminster and London medical societies, and still later of the Parisian Medical Society of France.

After remaining abroad some time he returned home, and patients flocked to see him from all parts of the world, who were treated and cured by the thousands. His patients becoming so numerous he opened a large private hospital in Boston, which was constantly filled for nearly thirty years. In all this time Dr. Heaton had kept his own experience. He *had* intended to make public the method for curing hernia, and to do so in connection with his only son, Dr. George A. Heaton, U.S.A., who died, however, while young in life and in the practice of medicine, from disease contracted in the service during the late war while serving as surgeon. His death was the signal for at least a temporary defeat of all such projects. The idea was given up. The father, stricken almost into the grave by the loss of the son, closed his utterance to all idea of that character, and was wending his own way towards the tomb, with the invention yet unplaced beyond his own hand; and the profession, though no longer incredulous, longing, for humanity's sake, that its greatness should be placed upon its proper pinnacle, and its fame, already acknowledged, be displayed far and wide. Later in his life, Dr. Heaton, whose health was failing and whose grief for the loss of his only son seemed to become more intense as the months rolled on, formed the acquaintance of Dr. Joseph H. Warren, of Boston, and between these two gentlemen there ripened a friendship of strong character. Dr. Warren was held by Dr. Heaton not only as his friend, but also as his physician in the days when the great mind succumbed to the ravages of illness, and the wasting life acknowledged the necessity of a brother physician's treatment. It was during his last illness that Dr. Warren, in the course of many conversations with Dr. Heaton, induced the latter to give to the public and to the profession a volume explaining the simple methods of the cure that had made him so famous. This need not be described, even if there were space, for "Heaton on Rupture," although but a few years

(less than four) on the list of text-books, is already standard and valuable to the profession, who of necessity, as well as honest candor, must acknowledge the praise that is due Dr. Warren for the persistent argument he used with Dr. Heaton, and the successful result he thus attained in procuring the publication of the volume. In the production of the many papers attendant upon the work, Dr. Heaton was assisted by Dr. J. Henry Davenport, whose skill in the preparation and edition is deserving of no slight praise. To Dr. Warren is due the honor of obtaining for the use of the profession the golden secret, which but for the friendly advice and persistent appeals of that physician would have gone to the grave with the inventor. It might naturally be supposed that before the close of his life Dr. Heaton bequeathed to Dr. Warren the original and simple instruments with which he had performed such a multitude of cures, and in the pursuit of a practice that also followed Dr. Heaton's wishes. Dr. Warren has brought the simple tools into successful use on his own and Dr. Heaton's patients, who are all now referred to Dr. Warren.

Dr. Heaton was the possessor of very great wealth, obtained in his practice. His efforts were worthy of it, and his invention demands that his fame should not suffer with his death. The friendly appeals that induced him, almost against his settled determination to give no details of his discovery and no guide to the future profession of medicine, are as well entitled to their credit, and the act of Dr. Warren in inducing his friend to add another link in an honorable chain that surrounded his career must have its high allowance by medical men and by the world at large.

That honor which is due men for any achievement redounding to the benefit of their fellow-men should never be withheld.

Boston, July, 1879.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 13 to July 19, 1879.

SMITH, JOS. R., Major and Surgeon. Having reported in person at Headquarters, assigned to duty as Medical Director of the Department, to take effect from 25th instant. G. O. 8, Dept. of Texas, June 28, 1879.

MOFFATT, P., Capt. and Asst. Surgeon. Having reported at Headquarters, assigned to duty at Camp Winfield Scott, Kittitas Valley, W. T. S. O. 81, Dept. of the Columbia, July 3, 1879.

CORSON, J. K., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 75, Dept. of Arizona, June 27, 1879.

KANE, J. J., 1st Lieut. and Asst. Surgeon. Relieved from duty at Jefferson Barracks, Mo., and to report to Commanding General, Dept. of the Missouri, for assignment to duty. S. O. 164, A. G. O., July 15, 1879.

BREWSTER, W. B., 1st Lieut. and Asst. Surgeon. To report in person to Commanding General, Dept. of the Platte, for assignment to duty. S. O. 164, C. S., A. G. O.

BANISTER, J. M., 1st. Lieut. and Asst. Surgeon. Relieved from duty at Columbus Barracks, Ohio, and to report in person to Commanding General, Dept. of the Missouri, for assignment to duty. S. O. 164, C. S., A. G. O.

APPEL, A. H., 1st Lieut. and Asst. Surgeon. Relieved from duty at Willett's Point, N. Y., and to re-

port in person to Commanding General, Dept. of Dakota, for assignment to duty. S. O. 164, C. S., A. G. O.

RICHARD, CHARLES, 1st Lieut. and Asst. Surgeon. Relieved from duty at David's Island, N. Y. H., and to report in person to Commanding General, Dept. of Dakota, for assignment to duty. S. O. 164, C. S., A. G. O.

CARTER, W. F., 1st Lieut. and Asst. Surgeon. Relieved from duty at Fort Monroe, Va., and to report to Commanding General, Dept. of Texas, for assignment to duty. S. O. 164, C. S., A. G. O.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending July 19, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.

HAVANA, AND THE COMMISSION APPOINTED BY THE NATIONAL BOARD OF HEALTH. — Advices from Havana bring the intelligence that the commission appointed by the National Board of Health of the United States for the purpose of studying yellow fever symptoms, development, and treatment, in Havana, is prosecuting its work there assiduously. Much local interest is manifested in the work, and hopes of beneficent results are entertained. During the week ending July 16th there were 117 deaths from yellow fever in Havana. The Commission consists of Dr. Chaillé, of New Orleans; Dr. Gutierrez, of Philadelphia; Dr. Stunberg, of the Army; Dr. Tryon, of the Navy and Col. T. S. Hardee.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION LIBRARY. — At its recent annual meeting, the American Laryngological Association determined to commence a Library, embracing books, monographs, and papers published in this special branch of medicine. It is the present design to establish the Library in the city of New York, and to place it at the service of all who have manifested an interest in the advancement of this specialty by contributions to its literature or other work. Books or pamphlets will be sent on application at the expense of the applicant. All contributions should be sent to the Librarian, Dr. F. H. Bosworth, 26 W. 46th Street, New York.

ANTI-VIVISECTION. — Prayer-meetings for the souls of the physiologists are being held in Edinburgh. Pamphlets are being actively circulated by the London Anti-Vivisection Society, and its agents are delivering lectures at various towns upon the terrible inhumanity of man.

CHRONIC SUPPURATIVE INFLAMMATION OF THE MIDDLE EAR.

A LECTURE DELIVERED AT THE MANHATTAN EVE AND EAR HOSPITAL, IN THE CITY OF NEW YORK.

By O. D. POMEROY, M.D.

(Reported for THE MEDICAL RECORD.)

PART II.

CHRONIC SUPPURATIVE INFLAMMATION OF THE MIDDLE EAR—APPEARANCES UPON INSPECTION—GRANULATION TISSUE AND POLYPI—ICHOROUS DISCHARGE—MEATUS TOO SMALL—DEAD BONE—HEALING OF DRUM MEMBRANE—TREATMENT—CLEANLINESS—ASTRINGENTS—MODE OF APPLYING NITRATE OF SILVER—ALUM—ACETATE OF LEAD—CARBOLIC ACID—ARTIFICIAL DRUM MEMBRANE—INCISION OF THE EXTERNAL MEATUS—PROTECTION OF THE EAR—TREATMENT OF GRANULATIONS AND POLYPI—TREATMENT OF DEAD BONE—MASTOID COMPLICATIONS—CEREBRAL SYMPTOMS.

GENTLEMEN:—At the close of the last lecture we were studying the *appearances upon inspection* in a case of chronic suppuration of the middle ear. I had directed your attention to the character of the discharge, to the appearance of the drum membrane, and to a peculiar pulsation sometimes seen in that vicinity. To continue our study, from that point, you may also observe *granulation tissue and polypi*. There seems to be a tolerably gradual progress from a swollen and hyperæmic membrane lining the tympanic cavity to a state of granulation tissue or polypi. The distinction I would make between granulations and polypi is simply one of size. Polypi may reach a size equal to the utmost capacity of the meatus externus, and extend outward so as to be visible at the concha. In such instances it will be seen that the polypus has lost its red color, and has become covered with a layer strongly resembling the epidermis of the skin. It is a kind of cutified mucous membrane. One word with reference to the diagnosis of polypi and granulations. We will suppose we have to deal with a polypus of moderate size. It will be seen as a red and usually rounded body, though it is sometimes nodulated. If we have to deal with what Toynbee calls the strawberry polypus, it will resemble in color and appearance the strawberry. When you see in the ear a rounded mass resembling a polypus, and are in doubt regarding its nature, pass a probe in and touch it, and if it moves considerably you may be satisfied that it is a polypus, and attached by a base somewhat narrower than the diameter of the growth. This manipulation must be done carefully, and, lest undue violence be done, it is well, perhaps, to wind the probe with a very small piece of cotton-wool.

Sometimes you will see an auditory canal that has been excoriated by an *ichorous discharge*. I have seen quite a deep groove running along the lower portion of the meatus caused in this manner.

The meatus is sometimes too large, in consequence of a chronic purulent process with ulceration and atrophy. When such a process extends the entire length of the auditory canal, the meatus externus may be twice the ordinary size. I have frequently observed this in children.

On the other hand, the *meatus* may be *too small*.

It was only the day before yesterday that we saw a patient here who had chronic otitis suppurativa, and near the middle of the canal was a narrowing which made the opening so small that it admitted the probe with only the smallest possible quantity of cotton wool wound upon it. In that case it was almost impossible to clean the canal.

Sometimes you will be able to see *dead bone*, but rather infrequently. You can, however, determine its presence by the use of the probe. The rough sensation imparted to it, and perhaps the mobility of a sequestrum, will indicate its presence. If the ear is properly cleansed, however, you will diagnose the presence of dead bone without much difficulty. I have reported a case in which the sequestrum involved almost the entire temporal bone, in which the patient recovered, with facial paralysis on the affected side, and, of course, absolute deafness.

HEALING OF DRUM MEMBRANE.

After the granulations or polypi have been removed and the discharge is partly or entirely arrested, healing of the drum membrane usually commences. The process is most interesting to inspect. I have often observed cases in which the changes could be noted for several years, and I have in a few instances been reasonably well satisfied that I have seen delicate bands of reparative material thrown across the perforation somewhat resembling a spider's web. Perhaps we need to exercise the imagination somewhat to make such an observation, but I am sure I have seen it. There is a case here now, perhaps some of you saw it yesterday. There was a perforation which had healed, and the evidence of this was as follows: the site of the inner border of the old drum membrane was indicated by the incurved portion. The new formation was at a somewhat deeper level, filling the gap made by the perforation, and was placed upon the mucous aspect of the drum membrane precisely as a patch is applied to the inner side of a break in a piece of cloth, the edges of the aperture being neatly turned in.

Frequently the perforate membrane will be so sunken that the edges of the perforation are in apposition with the promontory, and, in healing, may become firmly attached to it, thus closing the aperture, either with or without the throwing out of reparative material, and there is a condition produced very much like posterior synechia in the eye. In these cases you may find the drum cavity divided into two parts, and when an attempt is made to inflate the tympanum you can see movements of the anterior portion of the drum membrane opposite the Eustachian tube, while the posterior portion remains uninflated and uninflatable. Again, the membrane may move outwards in the periphery, but with the central adherent portion immovable.

We might naturally suppose, after the drum membrane had healed, that then the process was terminated; but that is not altogether true, and it is extremely interesting to watch these cases further. I have done this in some instances for several years, and have found that the drum membrane undergoes constant changes. These relate chiefly to the tendency in the cicatricial formation to take on continuous connective-tissue degenerations, approaching the condition of true fibrous tissue, and showing many elevations and depressions running in an irregularly radiate manner.

Treatment.—First and foremost in the treatment of this disease is *cleanliness*. Cleansing an ear properly comes almost under the head of a fine art. I very in-

frequently find those who are capable of cleansing an ear as well as it should be done. It is of the utmost importance that the cleansing should be perfect in order to make an exact diagnosis, and it is equally important as the first step in treatment. This is ordinarily done by means of a syringe, but I syringe ears as little as possible to keep them clean. I like to avoid the effect produced upon the drum-membrane by the current of warm water, and prefer to clean the ear by means of cotton-wool. The absorbent cotton furnishes us a most excellent means of removing the discharge; but if the quantity of discharge be great, the syringe must be resorted to. I would advise that the cleansing be done under sight, and that the manipulations should be as delicate and careful as possible. If you do not hurt the patient, it is pretty good evidence that you are not inflicting undue violence. When the ear has been properly cleansed, you may use *astringents*. Perhaps I have done as much as many others to introduce the use of nitrate of silver in the treatment of this disease. In this institution we have been in the habit, for a number of years, of dropping a few drops of a solution of nitrate of silver into the ears in purulent inflammation of the tympanum, with or without polypi and granulations, and certainly we have had better success with it than with any other plan of treatment.

THE MODE OF APPLYING NITRATE OF SILVER

is important. You may take from three to six drops and throw them into the ear with some little violence, draw the solution out, and then repeat the process several times, while the dropping-tube is still inserted in the ear. When that is done, you will find that the solution is stained by the discharge which has not been absolutely removed from the ear. By that means the application is made much more thoroughly than by any other method. [The dropping-tube we use at this hospital consists of a hard rubber catheter, with a soft rubber thimble upon its ring extremity.] If the application trickles down the Eustachian tube into the throat, there is no harm done; but, on the contrary, it may be beneficial. If the perforation in the drum-membrane is small, and it is evident that there is extensive purulent processes going on in the tympanum, and it is impossible to get the agent into the cavity, I should not hesitate to make an incision in the membrane, so that the medicament could be effectively introduced. Politzer's inflation may also be done to cleanse the cavity of the discharge.

The strength of the solution of nitrate of silver used is very important indeed. In this institution we use it of a strength varying from ten grains to the ounce to a saturated solution. Several years since I reported in the *New York Medical Journal* a case of this disease. The man was doing very well under the use of a strong solution of nitrate of silver, but the treatment seemed inadequate, and I finally used several drops of a 480-grain solution as previously described. It caused no pain, no discomfort, except a slight feeling of warmth, and the single application cured the patient [the membrane had a small perforation, with a little granulation attached to its border]. I may also say here that if there is evidence of purulent inflammation of the tympanic cavity without perforation, or with perforation too small to permit of the introduction of the solution into the cavity, a strong solution painted upon the drum-membrane will frequently arrest the purulent process. I commonly apply the nitrate of silver every second day. The solution should not be strong enough to cause pain.

Alum may be used either in powder or in saturated

solution. An objection to this remedy is, that it forms the so-called alum curds, which produce a similar effect to foreign bodies in the tympanic cavity.

There is an empirical element in the treatment of this disease. We do not always know certainly that any given remedy will agree with the patient, and may, therefore, be obliged to change from one to another. *Acetate of lead* is a valuable remedy, and may be used in solution varying from two to ten grains to the ounce of water. A few drops may be introduced into the ear several times a day. *Carbolic acid* is a popular remedy. It has fallen somewhat into disrepute, yet it is valuable, and it has the additional advantage of being disinfectant. It may be used of the strength of from two to four grains to the ounce of water. I have but little to say with reference to the use of washes in the ears to correct the odor of the discharge, for if the latter is arrested there will be little or no foetid smell. It would be comparatively useless to throw in a quantity of disinfectant fluid when there is present a quantity of decomposing and nasty discharge. First cleanse the ear, and then apply remedies which arrest the discharge, and you will have but little need of disinfectants. Besides the carbolic acid you may use the liq. sod. chlo., a drachm to the ounce of water several times daily as a disinfectant. *Sulphate of zinc* may be used of the same strength as the acetate of lead and in the same manner. If you have to deal with a case in which there is a relaxed condition of the lining membrane of the tympanum, it will be well to use absorbent cotton-wool and pack the cavity as full as possible. To do this well there should be little or no drum membrane left, and only a moderate amount of discharge. The cotton may remain in the ear from a few hours to several days, but should be removed whenever it feels uncomfortable.

An artificial drum-membrane is sometimes recommended to close the cavity and protect it from atmospheric changes. I have almost entirely discontinued its use for the reason that it acts like a foreign body, produces irritation, and excites discharge.

PROTECTION OF THE EAR.

I would recommend the patient to wear cotton in the ear constantly until he is cured. The cotton should be placed loosely in the ear and removed as often as it becomes in the least moist. We wish to avoid anything like maceration of the part, and desire to induce a state of dryness as far as possible. At the Foundling Asylum I observed that the meatus in a considerable number of cases was much too large, and in a certain other number so narrow that only a small probe could be passed in, so that a quantity of muco-pus was constantly retained.

On several occasions I incised the external meatus in a number of places in order to allow the discharge to have free exit.

TREATMENT OF GRANULATIONS OR POLYPI.

I am in the habit of treating granulations or polypi as follows: First, remove them. If the polypus is of considerable size you may remove it by a *Wilde's snare*.

But the snare is an extremely impracticable instrument, and I now rarely use it. It causes more pain than the forceps, and it will not succeed unless the polypus is of considerable size and quite pedunculated. I depend almost entirely upon *forceps* for removing these growths. For that purpose almost any variety of small forceps will answer. Small nasal forceps answer very well indeed.

The most artistic forceps are those devised by the

late Mr. Hinton, of London. But they are somewhat complicated, and expensive. I would avoid a *speculum*, if possible, in operating; but if the polypus is small you will be able to use a speculum to good advantage. I have devised a pair of mouse-toothed forceps that may be opened conveniently in a somewhat narrow speculum. It is a good instrument for removing extremely small granulations.

The moment you lacerate a polypus it will usually bleed excessively. You should therefore begin your operation by knowing where it is attached, and remove it with rapidity to avoid the hemorrhage that will embarrass your movements. If the drum membrane is pretty well swept away, you need have little fear of doing harm to the contents of the tympanum. To avoid the embarrassment of the hemorrhage you may drop in a solution of nitrate of silver, or the liquor ferri persulph.

The nitrate of silver renders the polyp more friable than before, and less slippery, causing it easier to be caught with the forceps, for these polypi are often as difficult to seize hold of as a jelly-fish would be.

After removing as much as possible of the polypus, you have to depend upon cauterization for the completion of the cure. I always begin with the *nitrate of silver*. For that purpose I employ the crystals, in saturated solution. My method is to take a fine probe, wind the tip with a piece of cotton, dip it in the solution, remove the excess by wiping on blotting-paper, and then apply it to every remaining portion of the polyp until it is completely whitened. If the nitrate of silver does not succeed very well, I then use the strongest *nitric acid*. This should be applied a little more carefully than the nitrate of silver, and in the same manner, for if the nitrate of silver touches adjacent parts it does but little harm, whereas the nitric acid may do much mischief. These agents failing, I use the acid nitrate of mercury. It has a similar effect to the others, but the reaction is often quite excessive. It is used in the same manner as the nitric acid, but is a remedy which must be used cautiously.

Burnt alum is sometimes of valuable assistance in removing granulations and bases of polypi. Of late *iodoform* has been used, and in some cases it does very well indeed. One objection to the remedy is its disagreeable odor.

TREATMENT WITH REFERENCE TO DEAD BONE.

Any directions regarding removal of dead bone may seem superfluous, but I will simply say that if the sequestrum is of considerable size, is moderately loose, and can be removed with the forceps without much violence, you can remove it. In the case which I have already referred to, I made several attempts to remove the dead bone. Each attempt was followed by considerable hemorrhage. By the advice of my colleagues, I desisted from using further violence, and after a time it came away of its own accord. If you find a spot of dead bone, polypi are almost always present in its vicinity, and you can introduce a properly constructed gouge, and chip away the necrotic bone, or a dentist's drill may be used for this purpose. As a rule this is not necessary, for the sequestrum usually exfoliates by natural processes.

Mastoid complications frequently occur in this disease, and it may become necessary to trephine, or to cut down and gouge out dead bone.

To combat cerebral symptoms, frequently developing in this disease, the general indications are to prevent any accumulation of discharge in any of the cavities of the ear, including the mastoid cells.

REMARKS ON OVARIOTOMY.

VALUE OF EARLY RECTAL USE OF QUININE AND OPIUM IN CONJUNCTION WITH FREE SUPPORTING DIET, AS MEANS OF DEFENDING THE SYSTEM AGAINST THE DANGERS OF THE OPERATION—ILLUSTRATED BY A SERIES OF SIX SUCCESSFUL CASES, THREE SINGLE AND THREE DOUBLE.

By NATHAN BOZEMAN, M.D.,

SURGEON TO THE WOMAN'S HOSPITAL OF THE STATE OF NEW YORK.

PART III.

CASE V.—*Both Ovaries Involved—Left, Seat of a Multilocular Cyst with Pedicle Looped over Corresponding Round Ligament of Uterus, and Twisted upon Itself Seven Times—Never Tapped—But Slight Emaciation—The Value of Dulness on Percussion over One Loyn as Diagnostic of the Location of the Tumor Illustrated—Tinct. of Iron and Quinine Used before the Operation—Double Ovariectomy with Antiseptic Precautions—Small Incision—Adhesions and Hemorrhage Unimportant—Both Pedicles Ligatured—No Drainage-Tube Used—Early and Continuous Support of the System by the Mouth and Rectum—Quinine with Opium Commenced, per Rectum, Two Hours after Operation—Peritonitis Violent—Resulting Fever High—Cinchonism at the End of Twenty-four Hours, with Control of the Pulse and Temperature—Speedy Recovery.*

MARY C., of Ulster County, N. Y., aged 22, unmarried, seemingly in strong and robust health, but slightly emaciated, was admitted to the Woman's Hospital January 9, 1879, with an abdominal tumor about the size of a man's head; girth of abdomen, thirty-five inches. In January, 1878, first noticed a diminution in the menstrual flow, and occasionally a deep pelvic pain, attended with more or less weariness upon walking or standing. About three months after this perceived, in the left iliac region, a small tumor, which could be easily pushed with the hand from side to side. Began now to have pains in the small of the back, the left hip, the left thigh, the left groin, and the left labium pudendi, which were always greatly increased just before and during the menstrual period, and after severe exercise. The examination of this tumor showed it to be of the left ovary, and probably of the polycystic variety. It rested mainly in the left iliac and lumbar regions, but could be readily pushed far over to the right side, especially its upper part. Owing to the great thickness of the abdominal walls, only a slight sense of fluctuation could be detected. In this particular it had very much the character of a solid tumor. The uterus measured two and a half inches, was antelexed, and the fundus was drawn to the left side to almost a horizontal position. Percussion over the left loyn elicited dulness. The tumor had not been tapped, nor was this deemed necessary at the time of the examination to complete the diagnosis. The great mobility of the tumor, its apparently long pedicle, and the freedom from extensive adhesions, fully justified, it was believed, an operative procedure.

In addition to the ordinary preparatory treatment of daily tepid baths with vaseline inunctions, regulation of the diet, and attention to the bowels, tincture

of iron, in fifteen-drop doses thrice daily, was ordered. Ten grains of quinine, given the morning before the operation, which was performed January 24th. At 2 P.M. the operation (antiseptic) was commenced by the small incision. The introduction, first of the flat abdominal searcher, and then of the hand, showed the way to be clear. Several cysts, one after another, within the tumor, were tapped, and the contained fluids found to be of different shades of color. In all, the fluid was thin, in one quite like water, and in another, the largest, dark grumous-looking. No adhesions of any account were found to exist, but when drawing the cyst through the wound, the pedicle was discovered to be twisted upon itself seven times, and looped around the corresponding round ligament of the uterus. In addition to the looping of the pedicle, the fold of the peritoneum containing the ovarian ligament was found to have been divided and cicatrized down to the latter, through constant friction or rubbing of the round ligament. In fact, the ovarian ligament was completely bare, and no doubt would itself have soon been divided by the same processes of traction and attrition. The twisted pedicle having been uncoiled, tied, and dropped in the usual way, attention was next directed to the condition of the other ovary. This was found the seat of commencing cystic degeneration, and was likewise removed in the manner described. There was considerable oozing of blood, which required long sponging. Afterward the wound was dressed antiseptically, as usual.

This specimen I presented to the New York Pathological Society, with an explanation of the probable mode by which the parts involved were brought into the rare and unique relationship above mentioned. (See reports of the Society, published in the issue of the New York MEDICAL RECORD, Vol. xv., No. 15.) Weight of tumor and contents not ascertained. Duration of the operation, fifty-nine minutes.

AFTER-TREATMENT.

Per orem: Nothing. Hypodermically, Magendie's sol., ℥x. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., ʒ iss. General condition: Slight nausea from the anæsthetic; urine to be drawn every six hours.

Evening: Pulse, 108; temp., 101 $\frac{1}{2}$ ° F.

January 25th.—Morning: Pulse, 124; temp., 102 $\frac{1}{4}$ ° F. Per orem: Milk porridge, ʒ vi.; whiskey, ʒ v. Per rectum: Sulph. quinine, grs. xl.; liq. opii comp., ʒ ij.; mashed beef, ʒ viij. General condition: Slept the greater part of the night, and a good deal to-day; complains of some pain; skin hot, but not dry; feels faint at times; urine dark-colored, though sufficiently free; vomited once; dreams in her sleep; no tympanites; *cinchonized* at the end of twenty-four hours.

Evening: Pulse, 140; temperature, 103 $\frac{1}{2}$ ° F.

January 26th.—Morning: Pulse, 118; temp., 100° F. Per orem: Milk and lime-water, ʒ iv.; beef-tea, ʒ ij.; whiskey, ʒ i. Per rectum: Sulph. quinine, grs. xxx.; liq. opii comp., ʒ iss.; mashed beef, ʒ iv. General condition: Slept only about an hour during the night, and but little more during the day; nausea and vomiting more or less all the time; throws up occasionally a dark brownish material; has but little pain or tympanites, but complains of a burning feeling inwardly; pulse full and strong; skin dry; headache; urine still dark-colored, but quantity sufficient; wants ale to drink.

Evening: Pulse, 112; temp., 101 $\frac{1}{2}$ ° F.

January 27th.—Morning: Pulse, 110; temp., 100 $\frac{1}{2}$ ° F. Per orem: Milk and lime-water, ʒ iv.; whiskey, ʒ i.; tinct. of ginger frequently. Per rectum: Sulph.

quinine, grs. xxxv.; liq. opii comp., ʒ iiss.; mashed beef, ʒ viij. General condition: Slept more during the night, but is restless and moans; much less nausea and vomiting; complains almost always of abdominal pain after vomiting; fluid thrown up greenish in color; menstruation appears; pulse fairly strong; skin still a little dry; urine drawn at regular intervals, which is still dark-colored, but not turbid; bowels moved; *tinnitus aurium* continues; tympanites very slight.

Evening: Pulse, 110; temp., 101 $\frac{1}{2}$ ° F.

January 28th.—Morning: Pulse, 98; temp., 101 $\frac{1}{8}$ ° F. Per orem: Milk and lime-water, ʒ iv.; beef-tea, ʒ ss.; whiskey, ʒ ij.; tinct. ginger and bicarb. soda occasionally. Per rectum: Sulph. quinine, grs. xxxvij.; liq. opii comp., ʒ ij.; mashed beef, ʒ viij. General condition: Passed a comfortable night; slept a good deal; only slight nausea and vomiting; feels some distress in the epigastrium, but no pain; face flushed at times; pulse softer; skin soft and moist; urine clearer. Ordered mixture of citrates of potash and lithia every three or four hours. Menstruation continues.

Evening: Pulse, 100; temp., 101 $\frac{1}{8}$ ° F.

January 29th.—Morning: Pulse, 94; temp., 100 $\frac{1}{8}$ ° F. Per orem: Milk and lime-water, ʒ xvi.; whiskey, ʒ ij.; mixture of potash and lithia. Per rectum: Sulph. quinine, grs. xxii.; liq. opii comp., ʒ ij.; mashed beef, ʒ vi. General condition: Passed a comfortable night; vomited only once; no tympanites or pain; sleeps enough; pulse good; skin moist and pleasant; bloody uterine discharge continues; urine dark, but less turbid.

Evening: Pulse, 96; temp., 101 $\frac{1}{8}$ ° F.

January 30th.—Morning: Pulse, 96; temp., 100 $\frac{1}{8}$ ° F. Per orem: Milk and lime-water, ʒ xx.; whiskey, ʒ ij.; mixture of potash and lithia. Per rectum: Sulph. quinine, grs. xv.; liq. opii comp., ʒ iss.; mashed beef and pancreatine, ʒ ij. General condition: Complains of nothing, and sleeps sufficiently; bloody uterine discharge less; urine clearer; dressings of wound found to be offensive; removed and sutures taken out; wound completely closed, except a small point at the lower angle. From this opening there had been a considerable bloody discharge, causing the offensive odor; but this was discovered to be from the line of incision, and not the peritoneal cavity. Adhesive strips and new carbolyzed dressings applied.

Evening: Pulse, 104; temp., 100 $\frac{1}{8}$ ° F.

January 31st.—Morning: Pulse, 86; temp., 100 $\frac{2}{8}$ ° F. Per orem: Milk and lime-water, grs. xx.; whiskey, ʒ i; beef-tea, ʒ ij. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., ʒ ij. General condition: Vomited twice this morning, but is progressing well in every other particular; wound examined and dressing renewed; discharge only slight, and almost without odor.

Evening: Pulse, 100; temp., 100 $\frac{2}{8}$ ° F.

After this nothing worthy of note occurred. The next day both the pulse and the temperature fell below 100, and only once or twice afterward reached this point. The quinine in five-grain doses, with the usual quantity of opium, was continued till the ninth day, and then discontinued entirely. During the week of active treatment 225 grains of quinine and 15 drachms of liq. opii comp., with one hypodermic, were taken, and the balance of the time 50 grains of the former and 3 drachms of the latter, making in all: quinine, 275 grains; and liq. opii, 18 drachms. Week's average of pulse, 105; of temp., 101°. Convalescence was uninterrupted.

CASE VI.—*Multilocular Cyst of Left Ovary—Origin Associated with Persistent Fever and Ague—Never Tapped—Present Incomplete Procidencia Uteri and Persistent Headache—But little Emaciation—The Value of Dulness on Percussion over one Loin as Diagnostic of the side of the Tumor Confirmed—Iron, Salicin, and Quinine given before the Operation—Ovariotomy with Antiseptic Precautions—Small Incision—Adhesions Extensive—Hemorrhage Moderate—No Drainage-Tube—Pedicle Ligatured—Early and Continuous Nourishing Diet by the Mouth and Rectum—Quinine with Opium Commenced per Rectum one and a half Hours after the Operation—Peritonitis Mild—Cinchonism at the End of Forty-eight Hours—Pulse and Temperature for the Week almost Normal—Speedy Recovery.*

Anna M., of this city, aged 22; German, unmarried; healthy looking; was admitted to the Woman's Hospital March 4, 1879, with an abdominal tumor and girth of thirty-nine inches. She stated that in the autumn of 1877 she contracted fever and ague, which continued to recur at intervals from that time until the following April (1878), and that associated with this there was "falling of the womb." She then noticed that the menstrual flow was becoming more and more scanty and light-colored. Soon after she began to have deep pelvic pains, and found it difficult to turn in bed or leave the recumbent posture. A month or two later she discovered that her abdomen was considerably enlarged. For this and her womb trouble she sought advice in one of our general hospitals. After leaving this institution and applying to my friend Dr. S. T. Hubbard, of this city, for further treatment, she was advised by him to consult me. Upon examination at the time of admission into my service, I found the tumor reaching considerably above the line of the umbilicus. It was more prominent upon the left than the right side, and indicated, by its uneven surface, that it was probably of a polycystic character. Flatness on percussion to the left of the lumbar spine, coupled with the indications mentioned, led me to conclude that probably the left ovary was the one involved. The uterus, three inches in depth, was found in a state of incomplete procidencia; that is, it lay across the perinaem and projected beyond the vulva about one-half its length—certainly a very unusual complication of an ovarian cyst. The tendency of the latter usually is to drag the uterus after it, and not to push it out of the vagina. The tumor had never been tapped. The patient stated that she had had constant headache ever since the tumor showed itself.

Some five or six days before the operation the patient was put upon the use of tinct. of iron, 15 drops three times a day; but it was soon discovered by her that her headache was greatly increased by the medicine, and it was thereupon discontinued. Salicin, in fifteen-grain doses thrice daily, was substituted, and continued up to the night before the operation, when it was stopped, and ten grains of quinine ordered. The following morning ten grains of the latter, with one grain of opium, was again ordered. This, together with daily tepid baths, enemas, and the clearing out of the bowels, constituted the course of preparatory treatment. Careful measurement of the abdomen now showed a diminution in the girth of one and a half inches, and a proportionable increase of the mobility of the tumor itself.

Operation, March 21st.—At 2 P.M. the operation, under carbolic spray, was commenced. Small incision. Extensive adhesions of the tumor to the

omentum and abdominal walls. Only a small space, comparatively, to the right of the incision was found free, but nowhere were the adhesions very thick and resisting. The left ovary was found to be the seat of disease, and of the multilocular form, as diagnosed. It was made up of a large number of cysts, containing jelly-like material of different consistencies, and even fluid almost limpid. Only three or four of the largest needed to be tapped in order to enable me to draw the mass through the wound. After tying and dropping the pedicle as usual, the peritoneal cavity was thoroughly cleared of blood and debris, and then the wound united with waxed carbolized sutures and dressed antiseptically. No drainage-tube used. Weight of the tumor and contents, fourteen pounds. Duration of the operation, fifty-five minutes.

AFTER-TREATMENT.

Per orem: Nothing. Magendie's sol., hypodermically, ℥viii. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., ʒi.; mashed beef, ʒij. General condition: About one hour and a half after the operation, took first portion of quinine and opium; has vomited twice from the anæsthetic; slept two hours; pulse good, and skin moist.

Evening: Pulse, 114; temp., 99° F.

March 22d.—Morning: Pulse, 92; temp., 99½° F. Per orem: Milk and lime-water, ʒv.; milk, ʒi.; milk porridge, ʒi.; Magendie's sol., hypodermically, ℥x. Per rectum: Sulph. quinine, grs. xl.; liq. opii comp., ʒij.; mashed beef and pancreatine, ʒviii. General condition: Passed a good night; has not vomited since the effects of the anæsthetic passed off; some pain; drowsy, and sleeps quietly; pulse good; skin soft; urine normal; no tympanites.

Evening: Pulse, 100; temp., 100½° F.

March 23d.—Morning: Pulse, 98; temp., 99¼° F. Per orem: Milk and lime-water, ʒx.; milk porridge, ʒiv. Per rectum: Sulph. quinine, grs. lv.; liq. opii comp., ʒij.; mashed beef and pancreatine, ʒvi. General condition: Complains of nothing, and sleeps nearly all the time; one portion of the beef emulsion rejected by the rectum; thoroughly cinchonized at the end of forty-eight hours.

Evening: Pulse, 76; temp., 99½° F.

March 24th.—Morning: Pulse, 80; temp., 98½° F. Per orem: Milk and lime-water, ʒij.; milk porridge, ʒiv.; milk, ʒxij. Per rectum: Sulph. quinine, grs. xlv.; liq. opii comp., ʒij.; mashed beef and pancreatine, ʒvij. General condition: Slept nearly all night; no febrile symptoms, except a little headache, and turbidness of the urine, but in every other particular the condition is entirely satisfactory; no tympanites.

Evening: Pulse, 86; temp., 101° F.

March 25th.—Morning: Pulse, 80; temp., 99¼° F. Per orem: Milk, ʒxxv.; milk porridge, ʒij. Per rectum: Sulph. quinine, grs. xl.; liq. opii comp., ʒij.; mashed beef and pancreatine, ʒxi. General condition: Passed a comfortable night, and is progressing as satisfactorily as could be wished; cinchonism continues.

Evening: Pulse, 86; temp., 100° F.

March 26th.—Morning: Pulse, 79; temp., 99½° F. Per orem: Milk, ʒxl.; milk porridge, ʒvi.; beef-tea, ʒv. Per rectum: Sulph. quinine, grs. xxv.; liq. opii comp., ʒij.; mashed beef and pancreatine, ʒix. General condition: A little restless in the fore part of the night, but, excepting this, there is no unfavorable indication to note; no tympanites.

Evening: Pulse, 74; temp., 98½° F.

March 27th.—Morning: Pulse, 74; temp., 98½° F.

Per orem: Milk, $\bar{5}$ xxix.; milk porridge, $\bar{5}$ xij.; beef-tea, $\bar{5}$ iv. Per rectum: Sulph. quinine, grs. xx.; liq. opii comp., $\bar{5}$ ij.; mashed beef and pancreatine, $\bar{5}$ viij. General condition unchanged.

Evening: Pulse, 78; temp., $99\frac{1}{2}^{\circ}$ F.

March 28th.—Morning: Pulse, 78; temp., $98\frac{1}{2}^{\circ}$ F. Per orem: Milk, $\bar{5}$ xl.; milk porridge, $\bar{5}$ xxxij.; beef-tea, $\bar{5}$ xiv. Per rectum: At 9 P.M. last night all medication and alimentation by this mode were suspended. General condition satisfactory in every particular; bowels moved once; sutures removed, and union of the wound found throughout, excepting one small superficial point; not a particle of pus in the tracts of the sutures; adhesive strips applied, with renewal of antiseptic dressings and compress.

Evening: Pulse, 78; temp., $98\frac{3}{4}^{\circ}$ F.

No further medication being found necessary, the treatment was reduced to simply watching the patient and attending to her diet. The quantity of quinine taken during the six days of active treatment was 245 grains, and of the liq. opii comp., 13 drachms, with two hypodermics of Magendie's sol. of morphia. Week's average of pulse, 92; of temp., $99\frac{3}{4}^{\circ}$. Recovery in the highest degree satisfactory. The procident uterus returned to a simple prolapsed condition, and called for a mechanical support.

Since the foregoing portion of this paper was in great part written I have performed two more ovariectomies in the Woman's Hospital, and from the very great interest attached to these cases I append their results,* believing that they largely contribute to the support of the views I have thus far endeavored to maintain. The first case recovered promptly without an untoward symptom; occurred in an unmarried woman, $\text{set. } 29$; first abdominal enlargement noticed about one year ago; anæmia and emaciation marked, and cyst unilocular and firmly adherent. The second case was cancerous, and complicated with ascites and exhaustion; the patient died sixty-one hours after the operation.

In the two appended cases nearly the same general course was pursued as set forth in the above series. In the first case, owing to the complications present, the operation was more protracted than in any one of the series, the time taken being one hour and a quarter; but if it be correct, as shown by the report of Dr. Welch on the character of the tumor, that the origin was ovarian and not uterine, as was supposed, then there is no unusual importance to be attached to this circumstance. In the second case, however, the operation and its result stand in a light totally different from any one of the series given, since the disease for which the operation was performed was of a carcinomatous nature, and if its diagnosis had been clearly made out, I should not have performed the operation. But the diagnosis failing to a certain extent, the operation was performed, and the question now is, what disposition shall be made of the result? As viewed from a statistical standpoint it must be counted, but as regards the practical value of the general plan of preparatory and after-treatment for the operation of ovariectomy intended to be prominently brought out by this paper, the result in the case cannot, strictly speaking, be considered of any account. To make the most of the case, however, under the circumstances, it is claimed that even the final result of the operation, bad as it was, does not invalidate in the slightest particular the correctness of the principles of practice above mentioned. The value of this was just as clearly and satis-

factorily demonstrated, up to within a few hours of the death of the patient, as it was in any one of the series presented. The failure recorded is not in the quinine and opium treatment in conjunction with nourishing diet, to prevent, to moderate, or to control high temperature, since this was actually accomplished by the treatment in a more or less marked degree; but in the existence of a malignant disease, for the cure of which the resources of our art have not yet provided an adequate remedy.

General Remarks.—An examination now of the histories of the series of six cases upon whom ovariectomy was performed shows the following: The age of the patients varied from 22 to 65, the average being $39\frac{1}{2}$ years. One was married without offspring, two were widows who had borne one and two children respectively, and three were unmarried. In four cases general anæmia and emaciation were marked, and in the other two these conditions were present, but less appreciable on account of the shorter duration of the disease. In five cases percussion over the loins materially aided in the establishment of the diagnosis of the ovary involved. In one case the method failed on account of the increased length of the pedicle and the peculiarity of the fixation of the tumor on the opposite side. In the first two cases no particular attention was paid to the preparation of the system for the operation, further than to use for a few days the warm bath followed by vaseline inunctions and to clear out the bowels the night before. In the other four cases there was more or less preparation; for example, nourishing and supporting diet was employed in one; the same and quinine in another; the same with tincture of iron and quinine in a third; and the same with salicin and quinine in the fourth. The time taken for the operations varied from twenty-seven to sixty-two minutes, the average being fifty-two minutes. In all the operations the antiseptic method of Mr. Lister was employed. The small incision was adopted in five, and the medium in one operation. In four cases the parietal, omental, and mesenteric adhesions were extensive, resisting, and difficult to overcome, but unimportant in the remaining two. In three cases both ovaries were found diseased and were removed. In one case an ovary had passed around one of the round ligaments of the uterus and was followed by several coils of the pedicle. In all the cases the pedicle was transfixed with a double waxed carbolized silk ligature, then tied right and left, cut and dropped. No drainage tube was used in any case, and in only one was a tent left in the lower angle of the wound. In five cases the abdominal wound was closed with waxed carbolized silk sutures made to include the peritoneum. Through mistake the abdominal wound, in one case, was closed with plain silk sutures, and although no harm followed further than suppuration in their tracks, they are not to be recommended. In three cases the resulting peritonitis was violent, in one moderate, and in the remaining two mild. In one of the first two cases there were evidences of inflammatory products in the peritoneal cavity, but with no other result than protracted recovery (this was the Case in which cold water affusions over the abdomen were employed for forty-four hours); and in the other there was suppuration and discharge of pus through the wound on the ninth day, which resulted, as a matter of course, in protracted recovery. In the remaining four cases the recoveries were all prompt. In all six cases the average of the pulse for the week of active treatment was 98; that of the temperature for the same time, 100° F. In five cases free nourishment both by the mouth and rectum was em-

* The complete histories will appear in the reprints.

ployed, and in one by the mouth alone. In four cases nourishment by the rectum was commenced during the first day, and in two, by the mouth. In all six cases quinine and opium were given in combination, and invariably by the rectum. The quantity of the former given per day varied from 18 to 40 grains, the average being 26½ grains, and that of the latter (liq. opii comp.) for the same period, from 1½ to 2½ drachms, the average being 1½ drachms. In two cases the remedies were commenced one hour after the operation, in one two hours, in one eighteen hours, in one thirty hours, and in one (the first of all) seventy-two hours; the changes in time, for the most part in the series, being in the inverted order here given. In four cases decided cinchonism was produced, and in two, if present at all, it was so slight as not to be perceived by the patient.

Of the eight results recorded, seven were complete cures, giving a mortality of 12½ per cent.—7½ per cent. less than the average mortality attributed in the outset of these remarks to the practice of all operators. Again, counting the number of diseased ovaries removed, eleven, with only one failure by death,—which is a legitimate mode of presenting the subject—and the comparison is placed in a still better light. The failures would then stand at 9 per cent.

These eight cases, with one (successful) previously reported in this journal (Sept. 1, 1866), comprise my entire experience in the operation of ovariectomy, and altogether show a death-rate of 11.11 per cent. Prof. Nussbaum has said that if a surgeon could commence his career as an ovariectomist with the experience of twenty operations, he might expect in the course of time to record a respectable average of success. If the results here recorded teach anything, it is that a mere tyro may do this as well as the self-constituted ovariectomist with his twenty embodied experiences, if he will take the trouble to make himself familiar with the principles of the operation, and is patient and painstaking in all its requirements and details.

I think I have proven by my experience thus far that Prof. Nussbaum is in error, and that it is even possible for an ovariectomist to commence with a respectable average of success, if, as stated, he will only take the pains and trouble to do his work well, and above all, to bear in mind the time-honored maxim, credited to Sir Astley Cooper, "An operation done well, is done soon enough."

I know of no operator in this country who has cured eight out of nine of his first cases—88.89 per cent., the entire mortality being due to cancer; nor do I believe the records of the profession in Europe afford another example of an operator having secured in his *first* cases eight consecutive successes—100 per cent.

There are many eminent ovariectomists both at home and abroad who have had far greater success in a larger number of cases. To this fact I have already alluded. But their great success was not obtained at the beginning, nor can its superiority be used as an argument against a method which, so far as it has been tried, has yielded results quite as favorable, viewed from a scientific standpoint.

In conclusion, I wish to express my great obligations to my assistants, Drs. J. E. Janvrin and Henry Goldthwaite, for their full co-operation in carrying out the details of these operations. I am also under personal obligations to the house-surgeons, Drs. J. G. Perry, F. H. Hoadley, and Geo. E. Munroe, who deserve great credit for the patient faithfulness with which they watched these cases, and for the general accuracy of their observations and records of the after-treatment and its effects.

THE TREATMENT OF URETHRAL STRICTURE BY "SLOW" DIVULSION."

By GEORGE M. SCHWEIG, M.D.

NEW YORK.

WHEN I published a description of a new dilator (MEDICAL RECORD, No. 443), I had under treatment quite a number of cases of stricture, while others, with whom active treatment had been suspended, were under observation. In support of what I then claimed for the new instrument, I am now in position to furnish ample clinical proof, in the shape of a number of cases from private practice, but all accessible. While I will be first to admit that in none of the cases has the period of observation been as yet sufficient with certainty to predicate permanence of results, still I do not feel justified in withholding from the profession, for an indefinite time, facts the general knowledge of which I believe will prove conducive to the welfare of a large class of sufferers. When the gravity of the disease and the insidious development of incurable sequelæ are considered, I cannot but believe that the profession will gladly welcome a method of radical cure that is safer and less heroic than any other, and at least equally reliable.

Thus far my therapeutic results compare very favorably with those claimed for any other method, or a like method with other instruments. In judging of final results, I think some weight should be accorded also to the manner of obtaining them. If, therefore, equally good results can be arrived at by various methods, in one of which pain, danger, and liability to accidents are reduced to a minimum, while the history of the others bristles with instances of more or less serious hemorrhages, shock, urethral fever, urinary infiltration, and death, the preference is obvious. I have used my instrument now between seventy and eighty times, often dilating to 40 and 43 Fr., with not a single one of the accidents that are so common with urethrotomy as well as over-distention by other instruments. In no instance was there any reaction that amounted to anything, the average reaction being in fact far less than that attending the use of the ordinary sound or bougie. Not one of the patients was even for an hour prevented from pursuing his ordinary avocations. The mildness and safety of the treatment, therefore, leave nothing to be desired. For the few aphoristic remarks relative to the procedure contained in the paper above referred to, I propose now to substitute a somewhat more extended elucidation.

The term "Slow Divulsion," which I have chosen to designate the method, explains itself. Yet it is, from an anatomical standpoint, not always correct. By divulsion is meant rupture of a stricture. This is ordinarily obtained by rapid and forcible over-distention to a degree sufficient to accomplish the object, and is by no means a mild proceeding. It will be readily conceded, however, that if a stricture can be distended to a sufficient degree to destroy its resiliency—even though the process stop short of actual divulsion, all that is therapeutically requisite will have been accomplished. The object is to widen the urethra at a certain point or points, and prevent its recontraction, and if this can be accomplished by the over-distention of fibres without their actual rupture, it is equally well. In such instances, then, the term divulsion would be inaccurate. Wishing, however, to avoid a complex term, I have chosen for my method the above designation, as more nearly answering for the majority of cases than any other

that occurred to me. For the *modus operandi*, I refer the reader to the article previously mentioned.

Leaving aside impermeable strictures, for which by necessity either external or retrograde internal urethrotomy must precede all other measures, my experience has led me to consider urethral stricture a very simple matter, and easily disposed of. The chief difficulties that have heretofore presented themselves in its treatment were, 1, resiliency, and 2, the usual disproportion between the meatus and the other portions of the urethral canal. The latter of these difficulties has of late years been surmounted at the hands of some surgeons by enlarging (cutting) the meatus, at the cost frequently, however, of not only a disfigurement, but a serious disturbance of the urinary function. Both difficulties are obviated by my instrument, which possesses so great a percentage of distending power, that its employment makes it unnecessary to cut any but an abnormally small meatus (*vide* description of instrument).

In dealing with urethral stricture I have altogether abandoned after-treatment. The continued use of sounds for an indefinite period after other radical cures, so-called, I have found entirely unnecessary; and it is reasonable that it should be so. The sole object of its practice is to prevent recontraction. And if we go farther, and inquire into the nature and causes of this dreaded recontraction, we find it is twofold, viz.: First, that due to resiliency; second, the cicatricial contractions that follow both urethrotomy and divulsion with unsuitable instruments—where tissues are lacerated. If my method—as I claim—destroys resiliency without producing traumatism, it is obvious that neither of these two causes can obtain. I consider this dispensing with after-treatment a very important factor, because, instead of spinning it out to an indefinite period, it reduces the treatment of stricture to a few days or weeks. I have thus far asked my patients to call on me at first once a month, and then every three or six months, for a time, in order simply to pass a bulbous sound. Of the cases discharged as cured, I have as yet to record a first relapse.

It is a well-known fact that a large number of men, well up in years, suffer tortures from incurable affections of the bladder, kidneys, prostate, etc., referable to long-existing stricture. To reduce these cases to a minimum by *curing* stricture in its early stages is therefore a great desideratum. Now, there is a circumstance, very ridiculous from a scientific, but very formidable from a practical standpoint, that stands in the way of curing stricture more frequently than one would imagine. As every physician knows, most people stand in great dread of being cut; and where the necessity of this is insisted on as a means of radical cure, a large percentage prefer the disease to the remedy.

I have thought it unnecessary to ask the reader to wade with me through the dry details of cases, deeming it equally sufficient to epitomize these in the shape of results. I will add my earnest hope that both the method and the instrument (and I consider them inseparable) will receive an extensive trial at the hands of the profession, and I have no fear as to the results or the verdict.

495 LEXINGTON AVENUE.

Reports of Hospitals.

PENNSYLVANIA HOSPITAL.

A SURGICAL CASE OF UNUSUAL INTEREST.

A MAN of forty was admitted to the Pennsylvania Hospital, Philadelphia, on the 27th of April last, in the following extraordinary condition. There was a lacerated wound on the top of his head, three inches long by an inch and a half wide, and very deep. The integument had sloughed or been torn away, the bones were missing, the dura mater was exposed and sloughing, and the brain could be seen pulsating at the bottom of the foul mass. Strange to relate, the patient was perfectly rational, and gave the following remarkable account of himself: He was first officer in a three-masted schooner sailing from the West Indies to New York with a cargo of sugar. He had worked very hard at loading the vessel in the heat, and for two days and nights after sailing for home he was constantly on the watch. He suddenly became ill, and conceived the idea that the captain and crew were going to murder him and throw him overboard. To frustrate them he thought he would take his own life, and tried to jump overboard, but was prevented from doing so. On the fourth day out, when off Cape Hatteras, he got possession of an axe, and dealt himself several blows on the top of his head with the handle, fracturing his skull. He then, with the sharp edge of the axe, chopped out the softened mass, and picked away pieces of the bone. After this his head (mind) got better, he said. On the 25th of April, four days after inflicting the injury, the vessel arrived at New York. The patient walked to the cars and came to Philadelphia. He said that he was a temperate man; that he only took an occasional drink, and that he was not intoxicated when he injured himself. His appearance certainly did not indicate a man of intemperate habits. His story was so unlikely that it was, of course, doubted; but no cross-examination could elicit any contradictory statements, and he persisted in it to the last, bringing no accusation against any one—in fact, volunteering the declaration that the captain and crew were the best he had ever sailed with.

The patient remained in the hospital until May 31st, when he died. All pressure had been removed early in the treatment of the case, except where, as it was found, some pieces of bone had been driven down and buried under the sound part of the skull, and these did not produce any immediate paralysis. It was not until the thirteenth day after the injury that the man's left side became powerless. The pressure exerted by these pieces of bone was upon the anterior lobes. The case was regarded by the attending surgeon, Dr. William Hunt, as a fine illustration of the tolerance of these lobes. Both motion and sensation returned when the bones were removed, but the injury was too profound for the amelioration to continue.

The post-mortem examination proved the truth of the man's story. The calvaria showed twenty-five or more superficial slits and scratches, running parallel with the opening, which were exactly those that the edge of a sharp axe would have made. No murderer or set of murderers would have made such marks as these, and inflicted them all in one direction.

RELIEF OF ITCHING.—Pilocarpine has been used with success for the relief of itching in jaundiced patients. One-third of a grain is given hypodermically every night.—*Brit. Med. Journ.*

Progress of Medical Science.

ANATOMY OF TETANUS.—Within the last few years many observers have noted changes in the upper part of the spinal cord, the medulla, and the pons in cases of tetanus. In a case occurring in the New York Hospital, Dr. Amidon had an opportunity of verifying these observations, and he has endeavored to trace the origin of each set of symptoms to some central lesion. The inflamed pia mater surrounding the cord and including the anterior, posterior, and spinal accessory nerve-roots, explained the pain and stiffness in the back of the neck, as is shown by the existence of these symptoms in simple cervical spinal meningitis. On the vascular and cavernous lesions in the whole spinal accessory tract, and the inflamed pia mater about the spinal accessory roots, depended the dysphagia, spasm of the sterno-mastoid and trapezius, and spasm of the glottis, the excited state of the hypoglossal contributing to the production of the dysphagia. The lesions of the lower facial nucleus, considered by some as the centre for the muscles of the mouth, the only facial muscles implicated, gave rise to the "*risus sardonius*." The lesions found in the pons, by their action on the origin of the fifth pair, are outwardly manifested by the trismus, the constant, and hitherto unexplained symptom of tetanus. The lesions consisted principally of vascular and perivascular dilatations, and changes in the nervous substance itself, varying from simple vascular engorgement to areas of disintegration and the formation of vacuoles; they were found in the tracts occupied by the trigemini, part of the facial, spinal accessory and hypoglossal, while slight departures from the normal structure appeared in the glossopharyngeal and pneumogastric tracts.—*Archives of Medicine*, June, 1879.

INCOMPLETE RETENTION OF URINE.—Dr. Alfred Jean, whose paper on this subject took the Civile prize in 1878, gives the following *résumé* of his work in the *Gazette des Hôpitaux*, May 6, 1879:

Incomplete retention of urine should not be regarded as an exclusively local affection. It may, perhaps, for a long time involve only the organs concerned in the secretion and excretion of urine, but these are the exceptional cases. Sometimes the attention of the patient is directed to the digestive apparatus, disturbances of which may be the initial symptom; but, whatever may be the beginning of the affection, always, or almost always the greater part of the economy becomes involved. The most important vesical lesion is the general hypertrophy of the bladder walls, affecting the muscular elements of the different coats as well as the interstitial tissue. Prostatic obstruction acts principally on the circular and plexiform layers of the vesical walls, giving rise most frequently to horizontal bands, while urethral obstruction affects the external longitudinal layer. These changes are due to inflammatory processes. Subsequently the hypertrophied muscular fibres become constricted and paralyzed by a new formation of connective tissue, and imperfect contractions of the bladder result. The hypertrophic cystitis is followed by a true interstitial cystitis. In the kidneys are found interstitial and suppurative nephritis (surgical kidney). The principal symptoms are frequent and painful micturition, stagnation of urine, incontinence, polyuria, digestive troubles, fever, sometimes continuous, sometimes intermittent. Then follows uræmic

poisoning and the cachexia. The prognosis is always very grave, except in cases of stricture.

CATARACT FOLLOWING TYPHOID FEVER.—As the etiology of cataract occurring in young adults is involved in considerable obscurity, the following observation of M. Trélat may prove interesting. He operated successfully for double cataract, on a robust peasant girl, twenty-five years of age. The most careful examination revealed none of the causes which are usually considered as originators of this evil. The age of the patient could not account for it; there was no interference with general nutrition; the urine contained neither albumen nor sugar, nor an excess of phosphates. Four years previously a sister of the patient, then about twenty-four years of age, was treated by M. Trélat for the same affection, and a similar want of ascertainable cause led him to examine the two cases together for some common cause. It was then found that in both cases, about three months before the commencing dimness of sight was first noticed, there had been an attack of typhoid fever, and this, M. Trélat thinks, was the curious cause of the cataract, the changes in the lens being analogous to those induced in the muscular tissue.—*Gazette des Hôpitaux*.

CHEST MENSURATION IN PHTHISIS.—The following are the conclusions arrived at by Dr. Porter, after several years' attention to this subject:

1st. In the normal chest the movements of the two sides are practically equal. This is especially true of the infraclavicular region, where the lungs are more nearly symmetrical, and the movements of the chest less affected by irregular muscular development. 2d. The relative expansion of the lungs is interfered with early in phthisis, by the loss of pulmonary elasticity, and the choking of the alveoli and bronchi. 3d. In phthisis, the antero-posterior diameter in the infraclavicular region after forced inspiration is greater on the healthy than on the affected side. Conversely, after a forced expiration, the diameter of the affected side is greater than that of the healthy side. 4th. Age, sex, and habit of life may modify the amount of chest-expansion, but only disease or deformity can make any marked difference in the movement of the two sides. 5th. Disease may be suspected when the difference in the expansion of the two sides is very small. This irregularity cannot be determined with sufficient accuracy by the eye, or even by the tape-measure, but a pair of calipers, with a graduated scale, are necessary.—*St. Louis Medical and Surgical Journal*.

TYPHOID FEVER.—Dr. Thorne Thorne's report to the Local Government Board on the extensive epidemic of enteric fever, which lately occurred in and near the towns of Caterham and Redhill, is of special interest in its bearings upon the question of the spread of the disease through drinking-water. All the houses invaded, with but few exceptions, were supplied by the Caterham Waterworks Co., and in the exceptional cases it was found that the patients were in the habit of using the company's water. The supply was derived from chalk wells over 500 feet deep, and no possible source of contamination could at first be discovered. In the course of construction of some work, however, the company had employed men in one of the wells, at a depth of 455 feet from the surface, and it was ascertained that one of them, who left work some time in January, was believed to have been ill. After considerable difficulty the man was found, and Dr. Thorne was led to believe that he had been sut-

fering from a mild attack of typhoid fever at the time of his employment in the well. At that time the diarrhoea was very bad, and he was obliged to use the buckets, in which brick, mortar, etc., were lowered, and débris raised, to such an extent as to cause loud complaints from the men stationed at the top of the shaft. He stoutly denied having ever been so pressed as to have been compelled to relieve himself without the use of the bucket, but while above ground he was scarcely able to contain himself while running for the closet, and it is but reasonable to suppose that during his work in the well the water became contaminated. This state of affairs continued from Jan. 5th to Jan. 20th, when he was obliged to take to his bed. During his sickness he had not had medical attendance, owing to his poor circumstances, but the history of the case rendered the diagnosis reasonably certain. He had spent Dec. 25th and 26th at Croyden, where he probably contracted the disease. These dates correspond very accurately with this theory of infection: on Dec. 25th and 26th he was exposed to the poison at Croyden, and on Jan. 5th was taken ill; from Jan. 5th to Jan. 20th the water was poisoned, and from Jan. 19th to Feb. 30th an epidemic appeared in Caterham and Redhill, limited by the supply of the infected water. The village of Warlingham, however, was also supplied by this company, but escaped the epidemic. To explain this it was found that during almost the entire period of poisoning, the company had been obliged to draw a supplemental supply of water from another source, which was pumped into the farther end of the Warlingham main, and it is extremely doubtful whether this village received a drop of the product of the Caterham wells during this period. This is rendered more probable by the fact that, owing to the freezing of the service-pipes, the consumption of the company's water in Warlingham, during this fortnight, was at its minimum. The following suggestions, which Dr. Thorne laid before the Conference on National Water-supply, as combining the principal lessons to be learnt from this epidemic, were embodied in a resolution which received the unanimous support of the Conference:

"1. That the view, to the effect that even a comparatively minute quantity of the poison contained in the evacuations of enteric fever patients, may, when subjected to favorable conditions for the development of that poison, lead to the specific infection of very large volumes of water to which it has gained access, is fully borne out.

"2. That a special danger attaches to the mild—or as they have been termed 'perambulatory'—cases of enteric fever, by reason of the intensely poisonous nature of the diarrhoea which characterizes that disease.

"And, having regard to these facts:

"3. That all possible sources of excremental contamination, in the vicinity of water-sources, should be rigidly dealt with.

4. "That care should be taken, in connection with works for the conduction or storage of water, to exclude from employment all persons suffering from any diarrhoeal affection."—*The Practitioner*, June.

LYMPHATICS OF MUSCLES.—M. and Mme. Hoggan, in an article on the lymphatics of muscles, contend that lymphatic *culs-de-sac* without valves are found. There is a peculiar arrangement in the diaphragm, the origins of the *culs de-sac* being found on the peritoneal surface, while the pleural surface presents true lymphatic vessels, which have passed through the thickness of the muscle.—*Le Progrès Médical*, June 7th.

PASSIVE MOTION AFTER DISEASE OF JOINTS.—The movements of a joint after disease may be of two kinds, artificial or mechanical—made by means of various manœuvres and apparatus, or the natural or physiological movements produced by means of the muscles. The first are admissible when used to rectify malpositions of the limbs, and to treat confirmed ankylosis; but they should be rejected as useless or dangerous when proposed to prevent ankylosis. The second, on the contrary, are of great utility when employed at the proper time, restoring in a remarkable manner mobilization of the joints. Artificial immobilization at one time, natural mobilization at another, are the two principal therapeutic agents in the treatment of diseases of joints; one combats the anatomical lesions, the other restores physiological action. The first can be aided by topical, pharmaceutical, and hygienic agents; the second is favored by electrization of the muscles during the first stage, to prevent their degeneration. The best way to prevent ankylosis is to control inflammation. The only surgical means, strictly speaking, are continuous extension and, in extreme cases, resection.—*M. Verneuil, Le Progrès Médical*, June 7th.

KAVA-KAVA AND ITS BLENNOSTATIC PROPERTIES.—In a recent thesis on this subject, Dr. Dupuy states that the Kava plant contains a resin, which seems to constitute its essential therapeutic principle. The following are his conclusions concerning its medicinal properties:

1. Kava-Kava is a sialagogue.

2. Its action on the stomach is that of a bitter tonic; it improves the appetite without producing either diarrhoea or constipation, and perhaps acts as a prophylactic to catarrhal affections of the upper part of the digestive canal. Its taste is agreeable.

3. It exerts a special stimulating effect on the central nervous system; this stimulation differs essentially from alcoholic intoxication, and is called by Dr. Dupuy, *kavaic stimulation*.

4. It is not a sudorific.

5. It increases very markedly the excretion of water in the urine, and may be classed among the most efficacious of diuretics.

6. It does not produce priapism, as has been stated, but, on the contrary, it prevents it.

7. It is endowed with remarkable blennostatic properties, which manifest themselves very promptly. A chronic urethral discharge is first rendered more profuse, and is then promptly cured.

8. It is very efficacious in cases of acute urethritis or vaginitis, calming the inflammatory condition, controlling the pain during micturition, and suppressing the muco-purulent discharge from the urethro-vesical mucous membrane.

These results are probably due to the combined diuretic and blennostatic actions of the drug.

The anti-catarrhal action seems to be due to the resin, and the diuretic effects to a neutral, crystallizable principle called kavaine, and perhaps also to an alkaloid not yet discovered, whose presence would explain more satisfactorily the phenomena excited in the central nervous system, as well as the alterations in the circulation and secretions of the uro-genital apparatus. It possesses over other blennostatic agents, according to Dr. Dupuy, marked advantages, inasmuch as it produces neither diarrhoea nor constipation, is taken with pleasure, increases the appetite, relieves or controls entirely the pain during micturition, changes completely the nature of the discharge, and produces a cure in a very short space of time—ten days.—*La Tribune Médicale*, April 13th.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 2, 1879.

THE CAUSES OF DISEASE.

At present it must be confessed that the profession, although apparently satisfied as to the causation of the common diseases, are really much in doubt concerning the general subject. It is fashionable to ascribe to certain influences and conditions certain results. Theoretically, the connection can very readily, if not satisfactorily, be made out. For instance, the fashionable germ theory comes in to help us on almost all occasions; and by a certain habit of thinking into which we have drifted, and by yielding not a little to our imaginations, we mentally construct a superstructure which seems to explain everything. It is certainly very convenient to think we see what we cannot see, especially when we believe it necessary to account for what would otherwise be inexplicable. Plausible theories are always fascinating, and are, as a rule, generally accepted. In reality, however, few are based upon proper experience, thorough study, or indisputable facts. But this is the case the world over. The history of medicine is full of explanations of the causes of disease. Indeed, the profession has seemed to be as much interested in the various questions of etiology as in those of therapeutics. No one need be told that opinions concerning questions have been, and are still destined to change. Judging the future by the past, we are likely to be as much ridiculed in the next century for our blind belief in the power of unseen germs, as our forefathers were for their faith in the influence of spirits, of certain planets, and the like, in inducing certain maladies. It would seem almost like heresy to accepted doctrines to say that the germ theory does not explain everything, and that even the obnoxious sewer-gas may be innocent of the many grave charges which are constantly made against it. Still, we are willing to take the risks which such a position assumes. We are so apt to find, in a case of typhoid fever, that the well-water has been contam-

inated, that we are willing to look no farther. Even if such an apparent relation between cause and effect cannot be made out, we assume its existence by believing that the recognized cause is present, but that we are unable to discover it. This is very convenient reasoning, but very fallacious nevertheless. Contrariwise, how many cases of typhoid fever are known to occur in which the water has been perfectly pure, and in which all the usual sanitary conditions have been observed?

On the other hand, sewer-gas comes in as the father of almost all diseases. If a case of diphtheria occurs in a house, the sewer-pipe is looked after; if no leakage is discovered, the traps are declared to be imperfect, and the plumber rolls his eyes in thankfulness at being called thus early to save a family from certain destruction. Sewer-gas is pernicious, and too much care cannot be taken to exclude it from our dwellings; but when we consider that such a thing is impossible in a vast majority of instances, we naturally ask the question, why is not diphtheria more prevalent? We must admit that contaminated well-water is bad, that in certain persons, at least, it provokes grave, if not dangerous symptoms, but in the face of numerous facts, we are warranted in saying that such water is not the *sine qua non* in the study of the etiology of typhoid, of summer diarrhoea, or of cholera. The same may be said for sewer-gas. There is no doubt that it intensifies many diseases and modifies their course, but we are still unwilling to believe that it is an ever-present factor in the estimation of the etiology of diphtheria or any of the numerous diseases which are named in the same category.

The recent investigations which have been made concerning the causation of yellow fever also strongly militate against the germ theory, and many observers are convinced that the disease depends upon a specific poison of animal origin, like small-pox, measles, and scarlatina. We throw out these observations as straws which show the direction of the wind. The indications appear to us to be, that the germ theory is losing ground with advanced professional thinkers, that the necessity for studying the causes of disease anew is being forced upon our teachers, and that the time is not far distant when we shall cease to pin our faith so exclusively upon the power of floating germs, the far-reaching influence of bad well-water, and the omnipotent subtleness of sewer-gas.

THE ACTION OF ANÆSTHETICS.

THE third report on the action of anæsthetics to the Scientific Grants Committee of the British Medical Association has been made. The report embraces the results of investigating the condition of the blood-pressure in animals under the influence of chloroform, ethidine, and ether. The committee refer to a report of a committee of the Royal Medical and Chirurgical

Society (see *Trans.* for 1874, vol. xlvii.) to inquire into the uses and effects of chloroform, in which there is a brief, but very excellent record of the blood-pressure under chloroform and ether. That committee noticed that, on administering chloroform, there was at first a transient rise of the blood-pressure, followed by a gradual, but not a regular fall. It was also noticed that, when chloroform had reduced the force of the heart to the full extent, a rise of the mercury at once followed the respiration of fresh air.

With regard to ether, it was found that the primary rise was greater and more constant than with chloroform, and that the depressing effect was very slight or altogether absent.

By the experiments performed by the committee that has just reported, the above results have been amplified and more exact records obtained. The experiments were made upon rabbits and dogs. They make the general statement that on rabbits ether seemed to have no effect on blood-pressure, while ethidine reduced it to a considerable extent, but not to total extinction, like chloroform. The experiments seem to have been made with great care, and the facts obtained from the observations warranted the committee in reaching the following conclusions:

Ether, when administered to animals, has no appreciable effect in reducing blood-pressure; chloroform and ethidine have a decided effect in that direction.

Chloroform has sometimes an unexpected and apparently capricious effect on the heart's action. The occurrence of these sudden and unlooked-for effects, are a source of serious danger, because the blood-pressure is with great rapidity reduced to almost zero, while the pulsations are greatly retarded, or even stopped.

The reduction of blood-pressure by ethidine is not, so far as has been observed, by sudden and unexpected depressions.

Chloroform may cause death by primarily paralyzing either the heart or the respiration. Although not free from danger on the side of the heart and the respiration, ethidine is, in a very high degree, safer than chloroform, inasmuch as the former does not compromise the heart as does the latter.

A legitimate deduction from the facts given is that ether is by far the safest of the three anesthetics used, and that ethidine is much safer than chloroform, and equally efficient.

A MUSEUM OF HYGIENE.

THE Parkes Museum of Hygiene was opened in London on June 28th, with good prospect of becoming a useful and interesting institution. It is designed to be a centre of instruction for the public, and is officered by men of such high reputation in sanitary science as to insure a prospect of its accomplishing the object it proposes. It is intended to in-

clude in its collections everything, from literature to machinery, which may be of sanitary value, or incite to sanitary study.

We hope that the success of this institution may lead to the establishment of a similar one with us. There are few cities the population of which has a greater need than ours to be thoroughly acquainted with the ways of preventing disease. A museum which would be a centre for the diffusion of such knowledge, and which, by its existence and the display of its collections, would call attention to the progress that is made in it, could not fail to benefit the city. We are now constantly exposed to infection from without, and the development of disease from within. It appears that we cannot have our streets kept clean, nor can we pull down the wretchedly built tenement-houses that inclose them. It is possible, however, to diffuse more widely the fact of the danger of living beside a garbage-heap, of being fanned by the exhalations from a sewer, and of being personally or domestically unclean. Besides, sanitary science has now reached such maturity in knowledge, such richness in literature, and can show such ingenuity and skill in its mechanical and architectural devices, that it deserves a place where it may record its work and display its successes.

Museums of all kinds seem to find ready support and appreciation among our citizens. We recall the fact that the fossil tracks of the Thick-Toed Birds are elegantly displayed, and not infrequently gazed upon in Central Park, and that the Two-Headed Nightingale warbles to large audiences in the Bowery. There are, in addition, plenty of places where our moral or æsthetic sense may be feelingly appealed to, and we ask, why not create a museum whose prosperity would indicate something more than love of pure science, a fine artistic taste, or a morbid fondness for freaks of Nature?

VOLUNTEER SURGEONS TO HAVANA UNDER AUTHORITY OF THE NATIONAL BOARD OF HEALTH.

ADVICES from Washington, bearing date July 26, 1879, bring the intelligence that Surgeons Walter K. Schofield and Thomas Hiland, of the U. S. Navy, have volunteered for duty under the National Board of Health on yellow fever service; that their services have been accepted; and that they have been ordered respectively to duty at the Consulates at Matanzas and Havana, Cuba, where they will act as inspectors on vessels leaving for the United States.

The appointment of these officers will materially aid the health officers of all the ports along our coast which receive vessels from those localities at the present time suffering from yellow fever. No time should be lost in getting these volunteers into practical work, and all honor is due to them for undertaking their perilous mission. Their duty is to inspect all vessels sailing for America from the ports at which

they are stationed; and no vessel should be permitted to depart without the surgeon's certificate as to its sanitary condition and the health of the crew and the passengers.

With the aid of such officers, faithful in the discharge of their duties, it is believed by those whose opinions are entitled to respect, that the appearance of a case of yellow fever in an American port may be made a rarity.

Reviews and Notices of Books.

AMERICAN HEALTH PRIMERS. Hearing, and How to Keep It. By CHARLES H. BURNETT, M.D. Philadelphia: Lindsay & Blakiston. Pp. 152. 1879.

This is the first of a series of Health Primers edited by W. W. Keen, M.D., and to be written by various prominent American physicians. The opening volume is somewhat larger than those of the similar series of English Health Primers, and is equally well printed and illustrated. In order to make a book out of the subject of aural hygiene, allied topics must of course be brought in, and the author has in this case introduced his subject with a very clear exposition of the anatomy and physiology of the ear. As regards the care of the ear, there are many valuable and practical hints. The use of sweet oil, glycerine, and ear-spoons, for cleaning the ear, is cautioned against, and the syringe is recommended as the only proper instrument for this purpose.

The danger to the ear from surf-bathing is mentioned, and that pastime is spoken of in a rather depreciating way.

The book is well and carefully written, and gives promise that the Primer Series thus introduced will compare very favorably with the English one, to which, however, the American issue will be as much a complement as a rival.

ELEMENTS OF MODERN CHEMISTRY. By ADOLPH WURTZ, Professor of Chemistry in the Faculty of Medicine of Paris, &c., &c. Translated by WM. H. GREENE, M.D., Philadelphia: J. B. Lippincott & Co. 8vo, pp. 687. 1879.

This book is a translation of the fourth French edition, and embraces the latest facts in chemical science, including those of the liquefaction of gases, and the demonstration of the metallic character of hydrogen. There is a great number of text-books on chemistry in the field already, but we know of none that will fill the wants of the student so completely as this. It presents the facts of organic as well as inorganic chemistry, without being as voluminous as Fownes', as condensed as Barker, or as unsystematic as Roscoe. The theoretical part is clearly told, the progress of the exposition being illustrated by experiments. A large proportionate space has been, very properly, devoted to the metalloids, a knowledge of these, as the author states, being not only indispensable, but also more attractive to beginners.

There is something of a preponderance also of organic chemistry over inorganic, and the array of formulæ will appear somewhat discouraging to the student. Such a prominence, however, is almost a necessity from the immense number of facts now accumulated in regard to the carbon compounds.

The book is excellently printed and fully illustrated.

A TREATISE ON GOUT, RHEUMATISM, AND THE ALLIED AFFECTIONS. By PETER HOOD, M.D. Second edition (revised and enlarged), with a chapter on Longevity. Philadelphia: Lindsay & Blakiston. 8vo, pp. 431. 1879.

The second edition of this work is a deserved indorsement of its value and interest. Dr. Hood, its author, writes not as an experimenter or theorist, but as one whom thirty years of practical experience entitle to be considered authority on the subject of which he writes. A large part of the work is devoted to the consideration of the cause and nature of gout, and in this connection the various theories of its pathology are discussed at much length. The vascular turgescence theory of Dr. Gairdner, the chemical theory of Dr. Garrod, and the combustion theory of Dr. Bence Jones, are each of them set forth very clearly, but none are accepted as embracing more than part of the truth. The author indeed, while destroying the systems of others, fails to present any very definite one of his own. He is inclined to lay much stress upon changes in the fibrin and other constituents of the blood, and to deranged function of the liver and nervous system. He seems to be most strongly impressed, however, with the idea that in gout there is a materies morbi in the blood which should be eliminated, and that then a proper nutritive equilibrium should be established in order to prevent future attacks. This idea cannot be considered strikingly new. Indeed, whatever be the refinements in the pathology of gout, the main idea can always be expressed broadly in the humoralistic terms of Sydenham, who says: "The quitting of bodily exercise of a sudden causes the excrementitious part of the juices, which was formerly expelled by means of such exercise, to lie concealed in the vessels and feed the disease."

As regards treatment, colchicum, though admitted to be a specific for the attack, is asserted to be a dangerous remedy, and one to be used with caution, if at all. The author uses, during the attacks, a cholagogue cathartic, and he follows this with alkalis and others. Locally, the use of laudanum and whiskey has pleased him more than any other remedies employed.

The chapters on rheumatism and longevity present the subject well, but furnish us nothing particularly new.

The book on the whole is an excellent one, and the author, in spite of a certain diffuseness of style, has made it interesting throughout.

AN INTRODUCTION TO PATHOLOGICAL AND MORBID ANATOMY. By T. HENRY GREEN, M.D., Lond.; Fellow of the Royal College of Physicians, Lond.; Physician to Charing-Cross Hospital, etc., etc. Third American, from the fourth revised and enlarged English edition. With one hundred and thirty-two illustrations. Philadelphia: Henry C. Lea. 1878.

This manual of Pathology has passed through three editions, and has been well received by the profession. The fourth revised edition is before us, and in it the general high character of the work is maintained. It contains much new matter, the object of the author being to make it a more complete guide for the student. The arrangement and choice of subjects has made the book very satisfactory; and for the student of morbid anatomy, or the general practitioner who cannot spare the time to study extended treatises, the concise statements which it contains will be found very serviceable. It would be pleasing to give special reference to the various subjects which have been presented, but this seems to be superfluous, for the reason

that the general contents of the book are already well known to students and the working members of the profession. The recent additions are the chapters on tissue changes in pyrexia, on fibromata, and on leukemia. The pretensions of the book are modest and meritorious.

PHOSPHATES IN NUTRITION, and the Mineral Theory of Consumption and Allied Diseases. By M. F. ANDERSON, L.R.C.P. Ed., etc. London: Baillière, Tindall & Cox. 8vo, pp. 200. 1878.

This book is rather a plea than a treatise. The author's theory is that there are two varieties of diseases of nutrition; one is due to *organic* innutrition, and includes starvation when organic food is insufficient or not assimilated, and fatty degeneration when there is deficiency of albuminates. The other variety is due to *inorganic* innutrition, and includes scurvy, rickets, scrofula, consumption, cancer, and leprosy. The supply of the proper organic food will prevent or cure these diseases. The author made many original experiments from which he deduced his theory. His work is evidently carefully done, and his conclusions deserve both study and trial, bearing as they do upon a class of obstinate or incurable diseases.

DIFFERENTIAL DIAGNOSIS, a Manual of the Comparative Semeiology of the more important Diseases. By F. DE HAVILLAND HALL, M.D. Philadelphia: D. G. Brinton. Pp. 205. 1879.

This is a book which will delight the student who is "cramming," and will be of much value to the general practitioner. It shows a very wide research among medical authorities for points in differential diagnosis, and the author and American editor have arranged their material with care and judgment. The work is essentially a compilation, but it is a reliable one, and we have found only a few points which are not as given by New York teachers. In addition to the differential diagnosis tables, are notes calling attention to pathognomonic symptoms, if such exist, and giving synopses of clinical history. With the increasing prominence which differential diagnosis is receiving, we predict a success for this manual.

A MANUAL OF PHYSICAL DIAGNOSIS. By FRANCIS DELAFIELD, M.D., and CHARLES F. STILLMAN, M.D. New York: William Wood & Co. Pp. 30. 1878.

The special merits of this book are that it is simply and clearly written; it is bound interleaved, so that notes and additions may be made; and it has sets of superimposed colored plates which show very perfectly the position and relations of the thoracic and abdominal viscera. The conciseness of the book and the excellence of the plates will recommend it to the student. It does not attempt the theoretical part of physical diagnosis, and it omits some of the minor and less important signs.

ATLAS OF HISTOLOGY. Parts I. and II. By E. KLEIN, M.D., F.R.S., Lecturer on Histology at St. Bartholomew's Medical School, and E. NOBLE SMITH, L.R.C.P., M.R.C.S. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1879.

This elegant work, which is now being issued in quarto form, is intended, as the preface indicates, to illustrate the minute anatomy of man and the other vertebrates. The drawings are nearly all by Mr. Smith, though a few are to be found in Klein's former works, such as his "Anatomy of the Lymphatic System." Blood is the subject of the first chapter; then follows Epithelium, Endothelium, and Connective Tissue,

with which the second volume is closed. Each chapter is written with care, and generally is succinct and clear. One of the first things we notice is that the authors give in their adhesion to the idea that the protoplasmic substance of the corpuscles consists of a network, at the nodal points of which are enlargements, which are the "granules" seen in the colorless corpuscles, and whose supposed active movements we have called "Brownian." The nucleus is said also to contain a similar network (intra-nuclear) which is continuous with the intra-cellular. Still, it is admitted by the authors that there are other granules within the meshes. The advantage of coloring in a work of this kind is apparent from the way that particles of vermilion are represented in the interior of a corpuscle after they have been "swallowed." Other corpuscles that have gone through this stage are seen to be busy ejecting them. The same intra-cellular and intra-nuclear network is attributed to epithelium, endothelium, and the fixed connective tissue corpuscles. As for membranes, this vexed question is decided in a way that may give comfort to both parties in the conflict over its existence or non-existence. Some epithelial bodies have them, it is said; others do not; it is not a real membrane in any case, but simply a condensation of the otherwise soft material. Cilia are said to be prolongations or continuations of an intracellular network whose contraction gives rise to "ciliary movement." When upon the subject of connective tissue, we are not surprised to find that the connective tissue corpuscle is first relegated to the endothelial group, and then made to be synonymous with the endothelial bodies themselves. It renders our conception of the relation between connective tissue and lymphatic spaces a much more simple one, even if it is not wholly complete or satisfactory. There is a lack of clearness about this part of the work that is disappointing, especially as just now we are looking for a final solution of these interdependent subjects. An attempt seems to be made to reconcile the views of some of the older German writers, while no notice is given to what has been done in England or America.

If the book has assumed an advanced position that all modern histologists cannot defend, it has the charm of usually stating its position in round and distinct phrases.

The drawings are excellent, and indeed have not been surpassed in any histological hand-book.

OBSTETRIC PRACTICE IN SIAM.—Medicine, and particularly obstetrics, seem to be in the most primitive condition in this country. Labor cases are generally attended only by ignorant women. If there is an emergency, male physicians are called in, but these are quite as bad as the midwives, and rely chiefly on incantations and absurd compounds for producing relief. To hasten on the uterine contractions the abdomen is pounded and kneaded, or even jumped upon. After delivery a most curious and painful ordeal has to be gone through with. The woman is placed as close as possible to a hot fire, and she is obliged to continue beside it for thirty days, suffering the agonies of a scorching heat and being only allowed hot water to drink. The custom is very firmly rooted, and no amount of persuasion will make the women do away with it. It has a certain scientific basis, from the Siamese standpoint, for it is believed that after parturition there is a diminution of the fire element in the system which causes the evolution of all sorts of bad humors.—*Archives of Medicine.*

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 14, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

(Continued from p. 92.)

ADENO-CYSTIC TUMOR OF THE OVARY—KIDNEY WITH DOUBLE URETER.

Dr. Lee also presented a specimen of adeno-cystic tumor of the ovary, together with the portion of the uterus to which it was attached, and one of the kidneys with a double ureter, from the same patient.

Mrs. H., *æt.* 30, married, and had had one child still-born five years ago. Was admitted to Woman's Hospital April 12, 1879. Menstruation regular since the time of her confinement, which occurred five years ago. After her confinement she noticed that her abdomen did not decrease in size, and consulted Dr. Budd, who told her she had an abdominal tumor. She had no pain, and her general health continued fair until three months ago, when she fell on her side, and had at once all the symptoms of acute peritonitis. That slowly subsided and left the abdomen altered in shape, although as large as ever. When admitted to hospital the abdomen measured 52 inches in circumference, and evidently contained a large, solid tumor, floating freely in fluid. Its character and origin were doubtful, but it was thought by Dr. Thomas to be an adenoma of the ovary. The tumor itself was not tapped, but the abdomen was, and the fluid obtained was doubtful in character. For ten days after admission to the hospital she did fairly well, when she suddenly had a succession of chills; the temperature ran up to 101 F., the pulse to 130, and, though little abdominal pain existed, all her symptoms pointed to the existence of septic peritonitis. The question of operation now became one to save life, and was done as a last resource. It was performed April 28th.

There were no anterior adhesions. When the base of the tumor was obtained it was found that it included the entire uterus. The pedicle, consequently, consisted partly of the uterus as well as of the broad ligament. An effort was made to separate the tumor from the uterus, but separation was found to be impossible, and it became necessary to include it with the tumor. The hemorrhage was very slight, amounting to no more probably than three ounces. The woman died from what seemed to be purely secondary surgical shock.

April 29, 1879.—Autopsy fifteen hours after death: External Appearances: Body emaciated. Incision in linea alba 20 ctns. in length, and extending nearly to symphysis pubis.

Heart: Decolorized post-mortem clot in right ventricle.

Pleura: Extensive old pleuritic adhesions on right side. Lungs normal.

Spleen normal.

Kidneys: Left kidney had two ureters, which have a common opening into the bladder.

Liver normal.

Peritoneum: Acute general peritonitis. Thick fibrinous deposits on visceral and parietal peritoneum, firmly agglutinating the intestines. A glass drainage-tube extended from the external incision into the vesico-uterine pouch. There was a small quantity of brownish fluid in the peritoneal cavity. No blood.

Uterus: The uterine cavity measures from the fundus to the external os, 9 ctns.; from fundus to os internum, 6 ctns. Thickness of its wall in middle of body, 1½ ctns. Its right cornu was included by a ligature, which also embraced the uterine extremity of the right Fallopian tube and adjacent portions of the broad ligament. The uterus itself was essentially normal. A number of ligatures included the stump formed by the structures above mentioned. The circumference of the stump at its base was 13 ctns. The stump had been drawn out of the external incision and held there by a long needle (Peaslee's needle).

Ovaries: There were no traces of the right ovary. The left ovary was somewhat enlarged, about twice the normal size, its external surface peculiarly convoluted, resembling the convolutions of a child's brain. Its cut surface presented several small cysts.

Rectum, bladder, and vagina normal.

Tumor: The tumor removed had a smooth surface, and contained a large number of cysts, with a large amount of solid tissue. The largest cyst was about the size of a child's head, and presented on its external surface an opening about 3 ctns. in diameter, and with lacerated edges, as if it might have ruptured spontaneously. Some of the cysts contained a brownish, limpid fluid, hemorrhagic; others a transparent thin fluid, and many of the smaller ones a yellow, viscid fluid, such as was frequently obtained from ovarian cysts. Brownish masses, with glistening specks, were contained free in some of the cysts. These were found, under the microscope, to consist chiefly of free fat and cholesterine crystals. In the fluid obtained from the cysts the so-called ovarian corpuscles were present. Large granular bodies, inflammatory corpuscles of Gluge, were also present. The measurements of the tumor were, laterally, 37 ctns.; vertically, 25 ctns.; antero-posterior, 15 ctns. On the lower surface of the tumor was attached the Fallopian tube, with its fimbriated extremity, through which a probe could be passed along the tube. The tube had been divided close to its uterine termination. The Fallopian tube on the tumor had the remarkable length of 31 ctns. The tumor was therefore a multi-lobular adenoma of the right ovary.

Dr. Lee further remarked that such tumors could be distinguished from solid tumors: *first*, by the entire freedom of the uterus when the tumor was moved; and *second*, by tentative gastrotomy. The diagnosis, by the presence or absence of a certain form of cell, was unreliable.

DR. PUTNAM-JACOBI remarked that the condition of the left kidney in Dr. Lee's first specimen seemed to indicate destruction of renal tissue, by reason of pyelitis, produced by a direct extension of inflammation through the ureter from the bladder.

DR. LEE remarked that he used the term Bright's disease because examination of the urine showed the presence of casts, and the history seemed clear that the diagnosis of Bright's disease before she came under his observation was correct.

DR. BRIDGON remarked that the fatty condition of the right kidney indicated the existence of chronic Bright's disease.

DR. KEYES asked if relief of vesical tonus was complete during the time the patient wore the glass tube.

DR. LEE replied that relief was complete up to the time of death.

DR. HOWE asked why dilatation of the neck of the bladder would not have answered as well as the cutting operation for the relief of the cystitis. He thought that dilatation in a patient having Bright's disease

gave a better chance of recovery than the use of the knife.

DR. LEE remarked that his experience did not enable him to answer the question. In the few cases, however, in which he had seen forcible or gradual dilatation of the neck of the bladder performed for the relief of cystitis in women, the success of the operation had been only temporary.

DR. HOWE regarded the cutting operation as more dangerous than dilatation.

DR. KEYES asked if any deaths had occurred after cystotomy in the female.

DR. HOWE replied that he had had no experience in cystotomy in the female.

DR. BRIDDON remarked that he regarded the cutting operation as the simplest and the safest. In a patient whom he saw, and who had both cystitis and pyelitis, the cutting operation was performed; not only without detriment, but with positive benefit.

DR. HOWE remarked that an essential difference between the cutting operation and dilatation was: in one instance, the risk attending exposure of a fresh and suppurating surface to urine must be taken; while in the other, no such risk obtained.

THE LARYNX OF A LEPER.

DR. LOUIS ELSBERG presented the larynx of a leper, and directed special attention to the change seen upon the tongue, upon the epiglottis, upon the arytenoid cartilages, and upon the aryteno-epiglottic fold.

Abraham Brown, *et.* 45, born in the United States, widower, and a bricklayer, was admitted into Charity Hospital, July 5, 1878. His family history was excellent. His previous history was, that about twelve years ago he went to Cuba, and was in Santiago three years. While in Cuba he was attacked with yellow fever. He never saw a case of leprosy while there. After leaving Santiago he returned to New York City, where he has been ever since. He noticed nothing about himself until February, 1878. Formication on the forehead was the first symptom noticed. It was accompanied by a feeling of malaise and general languor, being drowsy, and having frequent chills, but did not interfere with his work. In April, 1878, an eruption, in the shape of small tubers, appeared all over the face. Soon after this his eyebrows and lashes fell out. He had a feeling of numbness in his fingers; noticed that he was losing sensation in tips of fingers; could not appreciate the shape of objects as formerly. This was followed by the same condition on legs. Had no alopecia but that above mentioned; his eyesight has been failing him. Has had no venereal trouble, save gonorrhoea. Has had no marked general systemic disturbance since onset of the disease.

Present condition.—April 1, 1879. The patient has a very savage appearance. The integument very much discolored, being of a leaden hue. Has several tubers on face and forehead; on left cheek there are several tubers clustered together, and the remains of an old ulceration. Nose and lips are rough from the infiltration beneath the skin. Both lobules of the ears hang down like immense earrings. Body has an eruption on it, being quite dark in color. Arms and legs are covered with fine scales. Hands and feet have been very oedematous, but at present are not much swollen. Both hands are very tender, and present the following appearances: skin dry and thickened; show remains of ulceration of finger-nails. The first two fingers of the left hand show a hyper-extension. The nails of little and ring-finger have undergone ulceration, and are almost gone. The joints of the

finger are being rapidly absorbed, so much so that the last phalanx of the little overrides the second. Has general glandular enlargement. Ulnar nerves very thick and rigid. There is very little pain in them, and are not very tender. Right hand presents very much same appearance as left. Nails of the toes have undergone ulceration. Nasal passages affected; breath very offensive; voice very much impaired, and so husky that it is difficult to understand him. Tongue cracked, bleeds easily; saliva dribbles from his mouth. Gums are red and swollen. Following is a laryngoscopic examination, made by Dr. Elsberg last autumn:

“Palato-glossal and palato-pharyngeal folds have been ulcerated through and become adherent in several places. Inner sides of cheek and posterior wall of pharynx are dotted with small papillary excrescences. One large ulcer on hard palate. Patient has ozæmic catarrh, and although pituitary membrane seems to be injected, no tuberosities are present. Epiglottis tumefied. Its free edge thick and irregular, with angular lateral boundaries; hangs over larynx; ary-epiglottic folds congested and uneven, covered with a few large and small tuberosities. The lumps partially hide and give to the arytenoid cartilages an ill-defined and shapeless appearance. Posterior halves of vocal cords masked beneath the growth. Two large lumps are seen—one anterior, the other posterior to the left arytenoid. On its inner side vocal cords are of a dirty yellow color. In interarytenoid space one large tubercle stands out prominent into larynx.”

Patient complained very little. His general condition was good up to April 1, 1879. Complained then of a general soreness all over body. Has tenderness of lips and gums. Appetite fair. Emaciated. A temporizing prescription was ordered by the attending physician.

April 11th.—Ulcerations improving, and showing a tendency to heal, but no marked improvement over previous condition.

April 15th.—Feeling good, but wished a change of diet.

April 18th, P.M.—Complained to orderly of a feeling of oppression over chest.

April 19th, 8 A.M.—Was called down to see patient; said he felt badly, but could give no definite symptom. Slept very little during the night.

April 19th, 10 A.M.—Patient died suddenly. Heart and lungs not examined.

Autopsy made by Dr. Maxwell, Curator to the Hospital, twenty-eight and a half hours after death: Body of medium size, emaciated, rigor mortis present. (For external appearance, see description above.) Left leg and right arm atrophied.

Head: *Calvarium, dura, sinus* normal. There is only one vertebral artery (left). Pia mater and brain substance pale, otherwise normal.

Spinal cord and roots of spinal nerves: The latter on the right side, corresponding with the cervical and lumbar enlargements, show an increase in size equal to twice that of the roots on the opposite side. The nerves have almost completely disappeared, and the nerve-sheath is distended with a firm, yellowish, shining connective tissue. The nerves on the opposite side corresponding, show in some instances a slight degree of the same change. The lumbar nerves show nothing abnormal.

Cord: There is slight adhesion between the opposed surfaces of the arachnoid in the upper cervical region—posterior surface. The pia mater and cord substance anæmic. In the cervical and lumbar regions the lateral columns are firmer and grayer than normal (lateral sclerosis—localized). This was not

noticed in the dorsal region; the cauda equina shows nothing abnormal.

Thorax: Slight pleuritic adhesion on left side posteriorly.

Lungs: Right lower lobe, about two-thirds its surface and the whole of the middle lobe covered with a thin layer of fibrinous exudation. Base of its lower lobe shows an infarction about two inches in diameter, in yellow stage. The branches of the pulmonary artery on both sides, except the smaller branches, show at their points of bifurcation firm thrombi, yellowish in color, and quite intimately attached to the coats of the vessel. The largest of these thrombi are centrally softened. The only result of this thrombosis, with above exception, is collapse of the lungs. Surface of lungs pale. A small amount of vesicular emphysema in upper portions. Mucopus in bronchi.

Tongue and larynx: Upper surface of tongue shows a row of tubers on either side of the median line spreading out at the base, and at this portion a few are superficially eroded. The palato-glossal folds and the pharynx show a few nodules.

Epiglottis: Its tip for half an inch is thickened to extent of one-fourth inch; presents at its very tip an oval ulceration. On its anterior face a white, and at one point a puckered, cicatrix. Whole tip of epiglottis thickened, and the thickening seems to be in the mucous membrane, the latter sliding freely over the underlying cartilage. In median line is infiltration of the mucous membrane; at base of epiglottis, more yellow than normal, and in centre of this infiltration a superficial erosion. Orifice of glottis presents an oval, puckered appearance. The ary-epiglottic folds are irregularly thickened at their posterior attachments. The mucous membrane covering the vocal bands presents an almost uniform nodular thickening. The ventricular fold on the right side and the left vocal band present this condition most markedly. Below this, the mucous membrane of the larynx, trachea, and bronchi shows nothing worthy of note.

Heart: Pericardium normal. Weight of heart eleven ounces. Right side contained a post-mortem clot. The walls of about normal thickness, yellowish brown color, the trabeculae flattened. Valves: slight thickening of free margins of mitral and tricuspid, and a few scattered patches at the base of the aortic and on the anterior leaflet of the mitral valves. The aorta is thickened, its intima corrugated from chronic endarteritis. This condition extends most markedly throughout the thoracic portion, with a few calcareous patches. Blood thin, and has cherry-juice appearance.

Abdomen: Liver measures eleven inches in length, seven inches broad, and three inches thick. Weight fifty-three ounces. Cirrhotic. No amyloid reaction.

Spleen: Five inches in length, four inches in breadth, and one inch and a half thick. Weight nine ounces. No amyloid reaction. Shows in its upper border two old infarctions. Parenchyma pale, firm.

Kidneys: Chronic diffuse nephritis. Measure three and seven-eighths inches in length, two inches in breadth, and one and three-eighths inches in thickness. Weight four ounces. Somewhat diminished in size, capsules adherent, and when stripped leave a granular surface. An old infarction noticed on surface of right kidney. On section find cortical portion markedly atrophied, pyramids deformed. Columns of tubules cannot be traced above the bases of pyramids. Cortex has reddish-yellow color.

Pancreas and stomach normal.

Intestines: Mucous membrane shows patches of congestion.

Lymphatic glands: Mesenteric and retro-peritoneal glands normal. Deep inguinal glands enlarged and pigmented. Subcutaneous fat tissue, deep yellow color, and softened.

Muscles of body have dark red color, and the affected portions atrophied.

Nerves: Right ulnar above the elbow shows a fusiform enlargement two inches in length, and of almost stony hardness. Below this point the nerve is atrophied, and of yellowish color. The left ulnar shows only a slight fusiform enlargement at the elbow.

Left popliteal shows enlargement and hardness; the peroneal and sciatic are atrophied. The atrophied nerves are flattened, of dirty-yellow color, the nerve appearing to be more firmly attached to its sheath than normal. The nerve-fibres very much smaller than normal, of yellowish color, and seem to be bound together by a firm connective substance. The enlarged and firm portions of the nerves do not show so much atrophy of the nerve bundles, and the latter project beyond the level of the anterior surface, and have a gelatinous appearance.

The lumbar and sacral plexuses within the body show nothing abnormal.

CHRONIC VALVULAR DISEASE AT THE AORTIC ORIFICE, WITH FATTY AND WAXY KIDNEYS; DEATH FROM ACUTE CATARRHAL PNEUMONIA.

DR. BEVERLEY ROBINSON presented the heart, removed from a patient, aged 34 years, teamster, who died under his care at Charity Hospital, April 22, 1879. The patient had had syphilis several years before his death, and had suffered from intemperate habits.

The interest of the specimen related mainly to the condition of the leaflets of the aortic valve. The posterior and middle leaflet were fused together and at their point of fusion a hard, rough, and prominent calcareous mass could be seen and felt. The mitral valve and orifice were tolerably free from disease; a little thickening of the anterior leaflet and the attached cordæ tendinæ being the sole morbid lesions observed. At the post-mortem the walls of the heart were firm and of dark red color. Its weight was 14 ounces. There was evident hypertrophous dilatation affecting both sides. By hydrostatic test there was free regurgitation at the aortic orifice. Both kidneys presented distinct evidences of advanced fatty and amyloid disease.

As a clinical fact, it should be noted that the murmur heard during life was more intense with the first sound and near the apex than elsewhere.

CHRONIC LOCALIZED PLEURISY (R); CHRONIC INTERSTITIAL PNEUMONIA (RIGHT UPPER LOBE); ACUTE CATARRHAL PNEUMONIA (RIGHT MIDDLE AND LOWER LOBES); EMPHYSEMA, ACUTE EDEMA AND CONGESTION (LEFT LUNG); PARTIAL CARDIAC HYPERTROPHY; CHRONIC DIFFUSE NEPHRITIS.

Dr. Robinson also presented the right lung, removed post-mortem, from the body of G. W., aged 40 years, pianist, who died April 29, 1879.

Upon admission, April 24th, to the hospital, a few days before death, the patient was suffering from cough, dyspnea, and abundant yellow expectoration. How long he had had these symptoms could not be determined, as he spoke an unintelligible German patois. He had not apparently lost much flesh and his strength was sufficient to permit him to walk freely about the ward. His appetite was fair; his legs œdematous; micturition frequent; upon examination no albumen was found in urine; and the quantity passed was about normal. Physical examination revealed signs

of consolidation at apex of right lung, and those of emphysema at apex of left lung. Posteriorly and on the right side pneumonia was the diagnosis made by the house-physician.

On the day of patient's death, and only nine hours previous, he was suddenly attacked by a marked chill, followed by increased fever, notable pain in the chest, and excessive difficulty of breathing.

Pulse 134; respirations 47; Temp. 104 $\frac{1}{4}$ ° Fahr.

About three hours after the commencement of these accidents he saw the patient, and detected, as he believed, acute consolidation at the left apex, and at right apex and below this seat on either side in front, the signs of an older inflammatory lesion. He inferred that the actual aggravation of symptoms was caused by the extension of the acute pneumonic process.

The patient's condition was obviously so critical that he did not consider it advisable to raise him and make an examination of his lungs posteriorly.

The autopsy, made fifteen hours after death by Dr. E. A. Maxwell, showed the following:

Pleural cavities: Right shows bands of adhesion extending to costal layer from boundary line of upper and middle lobes; above this the cavity is filled with the fluid of chronic pleurisy. Below this portion both layers of the pleura show considerable thickening. Left pleural cavity normal.

Lungs: Right upper lobe consolidated by chronic interstitial pneumonia; lower lobe and lower portion of middle lobe consolidated by acute catarrhal pneumonia in gray stage. The left lung shows inflation overlapping the anterior mediastinum. There is general emphysema, congestion, and œdema. Both lungs show intense bronchitis.

"From the foregoing history and the morbid lesions revealed at the autopsy I wish to draw an analogy between this case of ambulatory pneumonic consolidation with chronic pleurisy of the right lung, followed by very rapid and intense generalized œdema and congestion of the entire *left* lung, and resulting in a speedy death, and those instances of sudden œdema of a relatively healthy lung, which occasion death after the operation of thoracentesis for large fluid effusions of the pleura.

"I believe the chill in the present case, which occurred the same day the patient died, was due to cold, which likewise occasioned the œdema in the left lung. After a like impression of cold we may have cases of rapidly fatal œdema in pleuritic patients from whom fluid has been aspirated. I do not believe, however, that the aspiration itself, as it has been stated, should be made accountable for that immediately dangerous complication."

FIBROUS PHthisis—LARYNGEAL PHthisis (SO-CALLED)
—WAXY LIVER, SPLEEN, STOMACH, AND INTESTINES
—OLD ULCERATIONS OF LARGE AND SMALL INTESTINES.

DR. ROBINSON also presented the larynx removed from a patient who had come under his care the day he died, for the purpose of having tracheotomy performed as a prophylactic measure of relief against excessive dysphagia and urgent dyspnoea. The lungs were already much altered by fibrous phthisis, and the apices were riddled with large and small cavities. The prospect of an ultimate cure was therefore almost hopeless. A laryngoscopic examination was not made, and, owing to the advanced condition of the intralaryngeal disease, as it is now visible, it may be doubted whether in this instance tracheotomy would have availed much, even so far as the mere relief of symptoms is concerned. As a general fact, however,

it is known tracheotomy does relieve very markedly advanced conditions of intra-laryngeal disease, and should therefore be performed when practicable, or unless there be some very formal contraindication. The condition of the larynx was as follows, according to post-mortem record made by Dr. J. F. Holmes:

"Lower half of laryngeal face of epiglottis is studded with nodular elevations (enlarged follicles). Mucous membrane of larynx quite pale; vocal cords appear to be considerably thickened and swollen, more especially the left; ventricular bands are also much hypertrophied. No evidences of ulceration in the larynx." To this description I would add that the epiglottis, ary-epiglottic folds, and arytenoid cartilages are all very much thickened and infiltrated. In fact, the entire larynx presents a typical case of so-called laryngeal phthisis. Are tubercles present? I do not believe they are.

This is the third case of similar nature shown by me to the members of the Society, and I am desirous that it should be examined carefully by the Microscopical Committee, and a report of what they shall find made at a later meeting.

DR. PUTNAM-JACOBI asked Dr. Robinson if he held the view that pulmonary œdema occurred after death?

DR. ROBINSON replied that he had entertained that belief.

DR. PUTNAM-JACOBI remarked that she had always regarded œdema as a vital condition.

DR. LEE remarked that the clinical point of interest in Dr. Robinson's case was the fact that extensive lung consolidation was not incompatible with considerable activity and vitality, and at the same time sudden death might occur in just such cases.

DR. ROBINSON remarked that he presented the specimen chiefly because of its interest in one point of view; it enabled us to draw an analogy between the cases of sudden death after thoracentesis from pleurisy, and sudden death from œdema of the healthy lung in a case of pneumonia. He attributed the sudden development of the œdema to taking cold.

DR. LEE asked Dr. Robinson whether he considered it worth while to perform tracheotomy in a recognized case of laryngeal phthisis?

DR. ROBINSON believed that all the symptoms could be relieved by the operation, and that it could be performed with a possible hope of effecting a cure. His conviction was that, in a majority of cases of so-called laryngeal phthisis, there were no tubercles in the larynx. He thought the profession should look upon the operation of tracheotomy as one almost demanded.

DR. ELSBERG remarked that, so far as he knew, he was the first to suggest and perform tracheotomy in laryngeal phthisis. He did not agree with Dr. Robinson with reference to the extreme rarity of tubercle in the larynx, but he was satisfied that tubercle was not present so frequently as some were disposed to think.

Scarification of the upper part of an enlarged and phthisical larynx, with the view of reducing its size, was of no service whatever.

A DIVERTICULUM.

DR. J. LEWIS SMITH presented specimens, accompanied by the following histories and remarks:

The first was a diverticulum from the ileum. It was removed from the body of an infant that died in convulsions, at the age of five months. The convulsions and death seemed to be due entirely to a severe broncho-pneumonia. There were no appreciable symptoms referable to the diverticulum. The point at which the diverticulum was attached to the ileum was just one foot from the ileo-cæcal valve, and

to that part of the intestine which was directly opposite to the attachment of the mesentery. At its attachment it had nearly the diameter of the adjacent gut. It gradually tapered from its base to its distal extremity, so that its shape was that of a symmetrical cone, which pointed forward when the abdominal walls were opened in the dissection. The entire length of the diverticulum when fresh was two and three-fourths inches. It was filled with gas, except the terminal half inch or the point, which was solid, and of a fleshy color and appearance; that portion had a cartilaginous feel, and communicated the sensation of a gritty substance when touched with the scalpel.

HERNIA OF THE CÆCUM.

The second specimen was removed from the body of a male infant, who died at the age of eight months. He was well nourished, and in good health till Friday, May 9th, when he became very fretful, as if in pain, and during the day the nurse observed unusual prominence in the right inguinal region. One healthy stool occurred on the 9th. On the 10th he continued fretful, had no stool, and several times vomited a greenish substance. A dose of castor-oil was administered, which was, however, vomited. The inguinal tumor continued as before, unless somewhat more prominent. On the 11th the condition was the same, except increasing weakness. Lime-water was administered by the attendants to relieve the frequent vomiting, but with no effect.

On the 12th he was rapidly sinking, and the nurse, now fully alarmed, brought him in the latter part of the day to the Dispensary of the New York Foundling Asylum, where Dr. Wilson, who was in attendance, at once recognized the nature of the malady, and sent him into the institution. Dr. Chadbourne, the resident physician, immediately examined the case, and made the following record: "Infant in collapse; limbs cold, face cool, features pinched, and eyes sunken; the tumor extends from the right inguinal region to the lower part of the scrotum. It has a dusky color, from the congested vessels underneath the skin; pulse feeble and quick; rectal temperature, $104\frac{1}{2}$; respiration, 80; the vomiting has ceased, and there is apparently but little suffering in consequence of the collapsed state." At 8 P.M., at the time of my visit at the institution, the patient was lying quietly on his back, the extremities cold, the pulse with difficulty counted on account of its rapidity and feebleness, but numbering about 180; rectal temperature, $105\frac{1}{2}$, respiration, 80; the features pinched, presenting the moribund appearance. The tumor could be handled without apparent pain on account of the low vitality. Having elevated the hips of the infant, an attempt to reduce the hernia by taxis was made. The testicle could be felt in the bottom of the scrotum, and the displaced intestine could be made to recede from it to the distance of perhaps one and a half inches; but manipulation and pressure to the extent which seemed prudent, although it diminished the apparent size of the tumor by crowding it against the ring, did not seem to produce any effect on the constriction. The displaced intestine could be felt within its serotal covering, soft, flabby, and without contents. It was deemed best, in the prostrated state of the patient, to apply cold to the tumor, and to stimulate actively by brandy during the night; but three hours later, at 12 P.M., clonic convulsions occurred, which terminated fatally at 5 A.M. During the night the patient had five stools.

At the post-mortem examination, made a few hours after death, the small intestines were found distended chiefly with gas, and there was a small amount of

serum in the abdominal cavity. The protruded portion of the intestine was the entire cæcum, and nothing else. The attached end of the appendix vermiformis was drawn within or against the ring, the body of this *cul-de-sac* lying above in the abdominal cavity. The ileo-cæcal valve was also drawn down, so as to lie against or perhaps just within the ring. The cæcum had a dusky red appearance in consequence of the congestion, and one portion of the size of a ten-cent piece was dark, as if from commencing gangrene. Subsequent examination, however, showed that there was no gangrene, nor was any offensive odor noticed. There was no fecal substance or gas in the cæcum. The points of interest were the following:

1st. This was obviously a case of acquired hernia. The fact that no protrusion occurred till the age of eight months certainly forbade our regarding the hernia as congenital. In hernia, which we may properly regard as congenital, the escape of the intestine through the ring occurs in the first weeks of life; and from cases of this kind, which have been observed, even those much neglected, it appears that strangulation is rare. For, if the aperture is so patulous as to allow protrusion at this early age, when there is little expulsive effort, and the position is usually recumbent, the return of the intestine by taxis is also easy. Dr. Smith had not met a case, which seemed to be congenital, which he could not reduce. On the other hand, acquired hernia in the infant, like that in the adult, is liable to strangulation, and it therefore requires prompt treatment. The cause of the unsuccessful result of taxis in the above case was apparent at the autopsy. The large size of the cæcum, its feebler peristaltic and vermicular movement, as compared with that of the small intestine, which movement greatly aids in the reduction when the hips are elevated, and the impaction of the end of the appendix vermiformis, and perhaps also of the ileo-cæcal valve in the aperture, through which the protrusion occurred, afforded sufficient explanation of the persistence of the rupture and its strangulation.

2d. From the few post-mortem examinations which he had made in cases of infantile hernia, which had been chiefly congenital, death having occurred from other causes, Dr. Smith believes that the large intestine is much more frequently the part which protrudes in infantile than in adult cases.

3d. Constipation was not so prominent a symptom as it usually is in strangulated hernia. Total constipation was present only during two days, and on the last day after the manipulation there were five stools. This was explained by the fact that the ileum was free, and the ileo-cæcal valve was barely engaged. The five stools in the last hours of life might, it was true, have occurred from fecal matter which was already in the colon, or the ileo-cæcal orifice might have been raised sufficiently above the ring by the taxis to allow fecal matter to pass. We could see by this case how strangulation and gangrene might occur in hernia, without obstructing the passage of fecal matter, provided that only the cæcum is engaged.

Dr. Smith also presented a specimen of *spina bifida* from an infant that died at the age of three weeks, which was referred to the Microscopical Committee. He also presented

A LUNG TAKEN FROM AN INFANT THAT DIED OF EMPYEMA.

Dr. Smith remarked it was a common belief that pleurisy with effusion, especially empyema, was a rare disease in young children. He had regarded it as quite the opposite; and as evidence of the correctness

of that view, he mentioned the fact that within five weeks he had seen three cases in which the diagnosis was verified by post-mortem examination. Within the same time he also had seen three cases in which the exudation was sero-fibrinous. At the present time, while scarlet fever was prevailing epidemically, quite a proportion of the children affected by that disease were attacked by pleurisy, and it was very apt to be suppurative in character.

DR. BRIDDON thought Dr. Smith's statement incorrect with reference to the frequency of protrusion of the cæcum in hernia occurring in children. It was generally the small intestine that was involved, and the occurrence of that form of hernia was also rare.

DR. SMITH remarked that he wished to say, that if comparison were made between inguinal hernia in the infant and in the adult, the large intestine constitutes the contents of the hernial sac in a larger proportion of cases in the infant than in the adult.

DR. ELSBERG asked Dr. Smith whether in such cases he considered attempts at taxis as effective as an operation.

DR. SMITH replied that in the present instance no advantage would have been gained by an operation, for the child was nearly moribund when it first entered the asylum. He hesitated to advise an operation, as he would to advise tracheotomy for a child cold, and nearly pulseless with membranous or diphtheritic croup. Besides, it must be confessed that in this case the return of the stools gave rise to a doubt as to the exact anatomical state.

DR. ELSBERG thought that under such circumstances an operation certainly could do no harm.

DR. BRIDDON remarked that he was not able to conceive of any condition that contraindicated an operation in a case of strangulated hernia.

The Society then went into Executive Session.

Correspondence.

A REMARKABLE CASE OF SEMI-CONSCIOUS EPILEPTIC AUTOMATISM.

By C. H. HUGHES, M.D.,

FORMER SUPERINTENDENT AND PHYSICIAN OF THE ST. LOUIS, MO., STATE LUNATIC ASYLUM, ETC.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The season is too hot in this latitude to justify a lengthy discussion of the question as to whether *unconsciousness* is an absolute essential of epilepsy and epileptoid.

But a recent very able lecture in your columns, by that most able lecturer and writer, Allan McLane Hamilton, asserts that "epilepsy is a malady which in all cases implies a recurring loss of consciousness," etc.; and the writer does not "believe that any act of violence which has been done while the individual is said to be epileptic or suffering from an attack of epileptic mania, can be excused unless there is at some time *absolute unconsciousness*."

As this is the sunstroke season, you will, I am sure, and so will Dr. Hamilton, pardon me for treating the subject with such brevity as will soon be apparent.

A large experience with epilepsy, and especially in the observation of epileptiform disease, has forced me to abandon, along with Mr. Hughlings Jackson, the criterion of unconsciousness as an absolute essential of the *status epilepticus*.

For the typical *grand mal*, unconsciousness is an unvarying characteristic; but in *le petit mal*, while a brief period of unconsciousness is almost the universal rule, it must be conceded that there do sometimes occur cases clearly attributable to this disease when an element of real consciousness, usually, however, a sort of dreamy consciousness, such as one sometimes feel just before waking exists.

Dr. Hughlings Jackson, in the fifth volume of the "West Riding Asylum Reports," 1875, in an interesting article "on the temporary mental disorders after epileptic paroxysms," sheds a flood of light upon the medico-legal aspects of epileptic states. Momentary lapses of memory—and acts of cerebral automatism after epileptic seizures are supplementary of them, as is often seen among the insane—are indeed very common.

I have seen some of these automatic acts come on as the precursor of the subsequent undoubted *grand mal*.

A medical friend of this city consulted me in regard to a gentleman who was first led to seek his advice, on finding that he had, without knowing it, while standing at his desk (he was the bookkeeper of his firm), filled up and signed his firm's note, tearing the note from the note-book and filling in the stub unconsciously, without attracting any one's attention by any convulsive or other singular movement.

This was unconscious cerebration, due to incipient epileptic disease; the case having left the city, and since developed into one of well-marked epilepsy.

The following case, however, is one of conscious automatic cerebration, due to undoubted epilepsy, and is the most remarkable case on record:

The case was referred by Dr. Rumbold, the editor of the *St. Louis Medical and Surgical Journal*, to Dr. Chas. W. Stevens and myself, and a careful inquiry elicited the following facts, which possess a medico-legal significance too obvious to require comment. I conclude this hasty prelude to the case with the remark that an extensive observation of epileptic and epileptoid states have gradually forced upon me the conviction that their mental possibilities are infinite—their vagaries being such as no man can yet number. We cannot be too cautious before courts in our estimate of the volitional element in the acts of epileptics and epileptoids. If a man may reveal his disease in so simple a thing as tearing up or eating a prescription blank just handed him by his physician, or wiping his nose on a piece of paper, or spitting on the floor when not accustomed to doing so, he may pull a trigger or cut a throat, and be, seemingly, conscious, or, as in the following case, do as he has often been wont to do, with the exception of not realizing that what he is doing, while it is not unnatural, is out of time and place.

In the fall of 1867 Dr. N. got up after midnight, dressed himself, walked a quarter of a mile to a certain place on his farm to look at his "stock." After he had been there a while, seemingly to him a very short time, he awoke to a realization of the fact that it was not the proper time for him to be at such a place; although conscious of every step he took to get there. He went back to his house, undressed himself, and again retired to bed.

He was conscious of all that he did from the time of rising to dress himself, but did not realize the incongruity of his position, and that he ought then to have been in bed.

In 1875 he again did about the same thing, getting up and dressing himself, putting on his boots, clothing, cravat, collar, and hat, and taking his watch from under his pillow and looking at the time, every

act being remembered in the order in which it was done. He this time walked out into the street.

When he fully came to a realization of the fact that he ought to have been in bed, he was standing by a fence looking over into a vacant lot. He knew he had come to the lot, but not that he ought not to have been there at that hour of the night, until after a time it occurred to his mind that he ought to have remained in bed, whither he immediately returned.

The patient had had many real epileptic seizures preceding these somnambulistic displays, his paroxysms being so violent that they so alarmed his second wife, to whom he had lately been married, that she has parted from him.

1313 CHOUTEAU AVENUE, ST. LOUIS.

AN AURIST'S EARLY DISCOVERY OF THE ANÆSTHETIC PROPERTIES OF ETHER.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The profession has shown an interest in every step that led to the final adoption of ether as a general anæsthetic, from Sir Humphrey Davy's experiments with nitrous oxide gas at the beginning of this century, and Pereira's allusion to the use of ether in 1839, down to Morton's final triumph in 1846.

But not to my knowledge has reference been made to the near adoption of ether as a general anæsthetic in 1829, and the fact is of such interest that I beg you will allow space in the RECORD for an account of it.

Having occasion to consult some of the older works on aural surgery in my library, my attention was arrested by the following line in a table of contents:

"Vapor of *Æther inhaled* (as assisting in the Examination of the Ear)."

The book I was consulting is entitled, "On the Varieties of Deafness, and Diseases of the Ear, with Proposed Methods of Relieving them." By William Wright, Esq., Surgeon Aurist to her late Majesty Queen Charlotte. London, 1829.

Turning to page 38 of this work, as indicated in the table of contents, I found the following paragraph:

"VAPOUR OF ÆTHER INHALED.

"It often happens, that there has been considerable herpetic eruption in the auditory passage, and the mere introduction of a piece of cotton wool, or even externally touching the ear to examine it, will produce a violent fit of coughing, through the irritation given to the fine fibres of the hard portion of the auditory nerve, which communicate the sensation to the nerves of the throat, etc.

"I have in these cases put a teaspoonful of ether into a cup, or evaporating dish, floating in a basin of warm water, and caused the patient to inhale the vapor, by merely breathing over the dish, which in almost every case will allay the irritation; and the cleansing of the ear can be proceeded in without difficulty. Some persons troubled with habitual cough, from chronic affection of the trachea alone, are peculiarly liable to have it excited by the slightest touch given to the lining of the tube of the ear; and having discovered that the above plan prevented the fit coming on, they have since constantly resorted to it with success, whenever the cough became troublesome."—(See *Aurist*, p. 79.)

Dr. Wright had, it appears, published this discovery even prior to 1829, in the *Aurist*, a serial which he edited.

Although the aural affection for which an operation

was required at the hands of Mr. Wright was not one of great magnitude, it was sufficiently painful to suggest the use of a quieting agent, and his description cannot now be read without exciting our wonder that he did not push the matter further and thus obtain more practical results.

We are led to the reflection, however, that many important discoveries are not the result of sudden inspiration, but that they emanate from the labors of many. For the final and uniform introduction of anæsthesia we are indebted to the peculiar art of Morton, who, when seized with the idea, never ceased to push it forward until successful.

SAMUEL SEXTON, M.D.

NEW YORK, July 18, 1879.

POISONING BY RHUS RADICANS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I wish to call the attention of the profession to the use of the liq. chlo. soda, or Labarraque's solution, in all cases of rhus poisoning. The acid poison requires an alkaline antidote, and this solution meets the indication fully. When the skin is unbroken it may be used clear three or four times a day, or in other cases diluted with from three to six parts of water. After giving this remedy a trial no one will be disposed to try anything else. It is one of the most valuable external agents known to the profession, and yet seldom appreciated, and but rarely employed. It will sustain its reputation as a local application in erysipelas, burns, and scalds.

Respectfully,

J. M. WARD, M.D.

CORNELIA, Mo.

A CONTRIBUTION TO THE SCIENCE OF ACOUSTICS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—This case, possessing great interest for the profession in general, is especially notable for being associated with a discovery which further explains the physiology of the voice, and on that account is of value to the science of acoustics:

A Case of Multiple Papillomatous Growths in the Larynx, extirpated by complete Laryngotomy; Removal of the whole length of both true and false Vocal Cords; Preservation of the Voice; Co-existence of Thoracic Aneurism. J. Burney Yeo, M.D., and Joseph Lister: Transactions of the Clinical Society of London, 1878.

The title of the paper explains the operation, as well as the disease for the removal of which it was performed.

The patient made a good recovery from the operation, which was performed by Mr. Lister, and it was found that he retained considerable phonetic power. His voice, however, was harsh and hoarse, still it had the characteristics of voice. He easily pronounced vowel sounds—of course at a low pitch—and he could read so as to be heard at some distance. Dr. Yeo found on laryngoscopic examination after the operation that the normal intra-laryngeal structures were entirely absent. The arytenoid eminences were seen, and also the ary-epiglottic folds stretching from them. When the patient spoke, while still under examination, these folds approached each other in the median line, and their vibrations gave rise to the sounds of the voice.

Mr. Lister was much surprised to find that this patient still retained his voice, although he expected he would be able to cough as well as other people.

Mr. Lister stated that he joined in bringing this case before the Society on account of its interest in connection with the physiology of the larynx. Mr. Lister had long ago observed that the stertor which sometimes occurs in patients under chloroform could be arrested by drawing the tongue out, not merely until the tip was well beyond the teeth, but until firm traction, or an additional pull, had made the organ even more tense. Further observations convinced Mr. Lister that the stertorous breathing was not owing to the action of the vocal cords, but to the vibrations of the pulpy, vascular portion of mucous membrane which surmounts the summits of the arytenoid cartilages—the posterior parts of the aryteno-epiglottidean folds. Mr. Lister regarded these cartilages as not only rotating upon their vertical axes, by means of which the vocal cords are approximated or separated, but that they have also a lateral movement, by which their summits, with the mucous membrane that clothes them, can be brought into mutual apposition in the middle line, or withdrawn from each other. The summits of these cartilages are also liable to an antero-posterior movement, by means of which the soft folds above them can be carried forward and applied to the base of the epiglottis, so as to constitute a secure valve of the entrance to the respiratory passage. Mr. Lister has discovered in his own person that when he made sounds, the portions of mucous membrane referred to passed forward to the base of the epiglottis, and were seen to vibrate in that position, producing what he has termed *laryngeal stertor*. The stertor could be made to pass into complete obstruction to the entrance of air when the pulpy masses were made to press more closely forward. When he drew his tongue firmly forward, sufficiently to occasion uncomfortable stretching of the frænum linguæ, the position of the epiglottis was not changed, but the mucous valve, independently of the will, retired backward, and a way was opened for the entrance of air. Mr. Lister further ascertained that these folds constituted the obstructing agent by which the exit of air is prevented during the expiratory effort which precedes coughing. The strain of coughing is thus removed from the delicate true vocal apparatus.

Mr. Lister himself produced the voice peculiar to stertorous phonation, and likened it to the sentence "Get away with you," which he had heard uttered by one little boy to another in the street, in a voice far too deep and gruff to have been produced at his age by the chordæ vocales.

ELECTRO-THERAPEUTICS AND THE AMERICAN NEUROLOGICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The tone of discussion on electro-therapeutics, assumed by the members of the American Neurological Association at their last meeting (as reported in RECORD of 12th inst.), is very much to be deprecated, for the following reasons:

First. It gives the idea to the profession at large that electricity can be applied in a hap-hazard way, with good chances of success.

Second. It shows them that those supposed to have most experience in the use of this powerful remedial agent, disagree as to the manner of its use.

Third. It gives them the admission of at least one of the instructors in this branch of medical science, that he treats without knowing which pole he uses.

They disagree so *very widely* in the most important points.

Dr. Grey could see a *physiological* difference between the poles, but no *therapeutical* difference.

Dr. Hammond knew there was a *therapeutical* difference, as witnessed in the treatment of ulcers.

It was admitted that the *positive* pole was more beneficial in treating ulcers than the negative, but why? I have used electricity many times a day for the past ten years, and have proven to *my* satisfaction that the *pole* used, the *direction* of the current, and the battery employed are of great importance. This can be demonstrated beyond quibble or doubt, by any physician of ordinary intelligence, by trying the different poles on the following diseases: insomnia, neuralgia, rheumatism, nervous prostration, painful dismenorrhœa, paralysis, strychnia-poisoning, cramps, etc. I believe many text-books extant on electro-therapeutics *muddle* more than they enlighten the general practitioner, and this discussion shows that the muddle is not confined *alone* to those who *learn*, for those who *have* and *do teach* seem to make muddle doubly muddling.

We ought at this late day to *know* something of electricity as a therapeutic agent, and if our best minds are as far at sea as this discussion would seem to imply, it is high time to appoint an investigating committee with power to send for persons and papers.

Respectfully,

J. D. S. SMITH, M.D.

BRIDGEPORT, CONN., July 15, 1879.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 20 to July 26, 1879.

MOORE, JNO., Major and Surgeon. Granted leave of absence for one year, with permission to go beyond sea. S. O. 171, A. G. O., July 24, 1879.

WHITE, C. B., Major and Surgeon. Granted leave of absence for six months on Surgeon's certificate of disability. S. O. 171, C. S., A. G. O.

SEMG, B. G., 1st Lieut. and Asst. Surgeon. Having reported in person at these headquarters, assigned to duty at Ft. Fred. Steele, Wyo. T. S. O. 61, Dept. of the Platte, July 15, 1879.

STORROW, Sam'l A., Major and Surgeon. Died at San Francisco, Cal., July 12, 1879.

CHRONIC BRIGHT'S DISEASE.—Dr. N. L. Guice, in a communication to *The American Bi-weekly*, gives the history of a case of chronic Bright's disease apparently cured by the use of iodide of potassium. The patient, aged 50, had suffered from malaria, but no history of syphilis was given. He became affected with Bright's disease, with all the characteristic bad symptoms. His urine contained a large amount of albumen, together with granular and hyaline casts. Iodide of potash was ordered in doses of gr. v. three times a day, and this was gradually increased to gr. xij. during the course of treatment. The symptoms slowly improved, and by the end of six months the patient appeared in every respect well. Iron and bitter tonics supplemented the potash. Five other cases of the successful use of the iodide in this disease have been reported.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—
Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending July 26, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
July 19, 1879.	0	8	69	4	53	22	3	0
July 26, 1879.	0	4	49	1	36	24	3	1

THE YELLOW FEVER.—There seems to be a public opinion that the disease in Memphis has been kept within certain limits by the general depopulation of that city. At all events, the fever has prevailed extensively during the last week, and has reached in mortality nearly the ratio said to be required to make it allowable to call it epidemic. To be declared epidemic the number of deaths during the week must exceed those from all other causes, and the President of the Board of Health thinks it doubtful if it can be declared so this season, because the latest week's death-roll showed thirty-four for yellow-fever and thirty seven for all other causes, and all that will remain in the city after camps have been established are considered yellow-fever proof.

From New Orleans one death is reported; no new cases.

In neither New York nor Brooklyn have any new cases developed.

DEATH OF DR. WILLIAM COOPER.—Dr. Cooper died at New Albany, Indiana, July 10, 1879, from cholera-morbus, after an illness of only twenty-four hours' duration. He was born in Chambersburg, Pa., in 1809, graduated from Jefferson Medical College in 1833, moved to New Albany in 1835, where he practiced medicine until his death. He was the oldest physician in that city.

THE NEW YORK ACADEMY OF MEDICINE.—Dr. Abraham Du Bois, of this city, has increased his donation to the Academy to \$8,000, for the erection of a fire-proof extension to the building now the property of the Academy, No. 12 West Thirty-first Street.

THE AMERICAN OTOLOGICAL SOCIETY held its annual meeting at Newport, R. I., on the 23d of July, 1879, Dr. Albert H. Buck, of New York, President, in the chair.

The attendance was large, and the papers read more than usually interesting. The following were presented: "On the Progress of Otology, Anatomy, and Physiology," by Dr. J. J. Vermyne, of New Bedford; "On the Progress of Otology, Pathology, and Therapeutics," by Dr. David Webster, of New York; "Clinical Remarks upon 1,500 Consecutive Cases of Ear Disease," by Dr. C. R. Agnew, of New York; "On a Case of Ménière's Disease Produced by Metastasis of Parotiditis," by Dr. H. D. Noyes, of New York; "A Contribution to the Pathology of the Temporal Bone," by Dr. Thos. R. Pooley, of New York; "On Facial Paralysis Accompanying Purulent Inflammation of the Middle Ear," by Dr. Clarence Blake, of Boston; "On Trephining the Mastoid in a Case of Acute Suppurative Otitis Media," by Dr. H. Knapp, of New York; "Exhibition of a Cochlea Discharged from the Ear of a Child Two Years Old," by Dr.

John Green, of St. Louis, Mo.; "A Case of Sarcoma of the Auditory Nerve," by Dr. George T. Stevens, of Albany, N. Y.; "A Case of Supernumerary Auricle of Rudimentary Development," by Dr. H. Knapp, of New York; and a paper on "The Treatment of Certain Forms of Diffuse External Otitis."

The society elected officers for the ensuing year as follows: *President*, Albert H. Buck, M.D., of New York; *Vice-President*, Chas. H. Burnett, M.D.

Dr. J. Orne Green, of Boston, who has served continuously as Secretary and Treasurer since 1870, and has contributed so largely by his ability and labor to the success of the Society and the complete arrangement of the Volume of Transactions, declined a reelection, and Dr. J. J. B. Vermyne, of New Bedford, was elected to that office.

Committee on Publication.—Drs. J. Clarence Blake, J. Orne Green, and J. J. B. Vermyne.

THE AMERICAN OPHTHALMOLOGICAL SOCIETY.—The annual meeting of the American Ophthalmological Society was held at the Hotel Aquidneck, Newport, R. I., beginning July 24, 1879, Dr. H. D. Noyes, of New York, President, in the chair.

There was a large attendance, and an unusually large number of papers were read and discussed at the morning and evening sessions of the first day.

At the morning session of the second day the following officers were elected for the ensuing year: *President*, H. D. Noyes, M.D., of New York; *Vice-President*, W. F. Norris, M.D., of Philadelphia; *Secretary and Treasurer*, R. H. Durby, M.D., of Boston; *Corresponding Secretary*, J. S. Prout, M.D., of Brooklyn; *Publication Committee*, E. G. Loring, M.D., and D. B. St. John Roosa, M.D., of New York.

The next annual meeting will be held in Newport.

The following papers were presented: "Exstirpation in Panophthalmitis," by Dr. George C. Harlan, of Philadelphia; "The Diffusion Circles of Ametropia," by Dr. A. G. Heyl, of Philadelphia; "Ischemia of the Retinal Vessels of both Eyes Following Facial Erysipelas," by Dr. David Coggin, of Salem, Ohio; "Case of Atrophy of the Optic Nerves in which Recovery of Vision followed the Injection of Strychnia;" also "Prolapse of Retina following Iridectomy for Glaucoma," by Dr. David Webster, of New York; "Demonstrations of Drawings of Some of the Rarer Forms of Eye Diseases," by Dr. W. F. Norris, of Philadelphia; "Paresis of the Inferior Oblique Muscle," by Dr. H. D. Noyes, of New York; "Presentation of a Tumor of the Optic Nerve of the Choroid," by Dr. H. Knapp, of New York; "Plastic Operations at the Inner Canthus," by Dr. H. D. Noyes, of New York; "On Operations for Entropion," by Dr. John Green, of St. Louis; "Notation of the Angle in Astigmatism," by Dr. J. S. Prout, of Brooklyn; "Description of a Perimeter," by Dr. Peter A. Carmalt, of New York; "Exhibition of a Trial Case of Glasses," by Dr. John Green, of St. Louis; "Statistics of Cataract Extractions," by Dr. H. D. Noyes, of New York; "Black Opacity on the Cornea and Tolerant of Foreign Bodies in the Iris," by Dr. L. S. Dixon, of Worcester; "A Case of Intraocular Tumor of Rapid Growth which Resulted Fatally," by Dr. J. F. Noyes, of Detroit; "A Case of Foreign Body in the Posterior Pole of the Lens," by Dr. T. R. Pooley, of New York; "Color Blindness, Tests and Visual Standards," by Dr. B. J. Jeffries, of Boston; "Enucleation of an Eyeball, followed by Immediate Recovery in a Case of Epileptiform Disease Associated with Diabetes Insipidus," by Dr. G. T. Stevens, of Albany; "Ophthalmic Notes, a Clinical Contribution," by Dr. C. R.

Agnew, of New York; "On the Operation of Complicated Cataracts," by Dr. H. Knapp, of New York; "On the Use of Atropine in the Treatment of Strabismus,"—"A Cosmetic Application of Glasses," by Dr. Green, of St. Louis; "Influence on the Refraction of Four Years of College Life," by Dr. R. H. Derby, of Boston; "Dacrocystitis of Nursing Infants," by Dr. C. J. Kipp, of Newark, N. J.; "Case of Sarcoma of the Conjunctiva," by Dr. E. Dyer, of Pittsburgh, Pa.

THE AMERICAN DERMATOLOGICAL ASSOCIATION will hold its third annual meeting in the city of New York on the 26th, 27th, and 28th of August, 1879.

BELLEVUE HOSPITAL.—Dr. Lewis A. Stimson has been appointed Visiting Surgeon to this institution, to fill the vacancy caused by the death of Dr. John T. Darby.

THE State of Michigan now takes the lead in the matter of Boards of Health. A recent law creates practically such a Board in every city, town, and village in the State.

DR. W. B. CARPENTER has resigned his position as Registrar of the University of London after a service of twenty-three years. In recognition of his work it has been resolved by the senators, graduates, and examiners to raise a fund for the purpose of procuring his portrait and presenting it to the University.

TREATMENT OF GONORRHOEA.—At the meeting of the Nashville Academy of Medicine, April 19th, the following propositions were put forward and accepted:

1st. That gonorrhœa, in spite of the greatest care, rarely yields to treatment within from three to six weeks.

2d. That the cause of failure is due to neglect on the part of the patient to observe the rules of hygiene and diet laid down by his attendant.

3d. That the best treatment is the internal administration of alkalies, the use of bland injections, and the exclusive milk and bread diet.—*Nashville Jour. of Med. and Surg.*

TREATMENT OF ACNE.—The treatment of acne punctata with glycerine and sulphur, as first proposed by Mr. Erasmus Wilson, is indorsed by Dr. J. G. Parsons, in the *British Medical Journal*. He thinks, however, that a far more efficacious way of applying the sulphur is to dust it upon the face every night. This will often effect a cure in one or two weeks.—*Brit. Med. Jour.*

ACONITE IN PNEUMONIA.—Four cases are related in *The Practitioner* in which aconite appeared to cut short pneumonia. The drug was given on the first day, when there were crepitan râles, cough, and rusty sputa. The tincture was given in minim doses every half hour for four hours, and then in minim doses every four hours. It seemed to have a sedative as well as abortive effect. It was considered especially useful in the first stage of pneumonia.

LIABILITY IN CATUETERISM.—Dr. T. Chas. Wilson, of Dewittville, N. Y., writes regarding the liability of the Jacques soft catheter to entirely slip into the bladder, and suggests that the liability can be removed by the addition of a rim or flange or other simple device to make it more safe to entrust to the care of the patient.

DETECTION OF FRAGMENTS OF STONE IN THE BLADDER.—Dr. Wooster Beach of this city suggests the following contrivance for detecting stone or fragments of stone in the bladder:

Take a piece of ordinary iron wire and bend it so

that at two points in its length it shall touch the ears, and at another point shall be in contact with a sound inserted in the bladder for exploration. A stone struck by the sound will announce its presence to the ears by means of the conductive power of the wire with great clearness.

The contrivance, in this form, although simplicity itself, and costing but the merest trifle, yields results, he thinks, fully as good as the complicated and expensive microphone.

"SPINA BIFIDA" TREATED SUCCESSFULLY.—Dr. N. B. Slade, of McConnellsburg, Pa., writes as follows:

"Mrs. M. gave birth to a male child with an aqueous tumor attached to the lumbar region of the spine. I immediately (before the child was washed) applied a stout silk ligature around the base or pedicle of the tumor, and with my bistoury evacuated it by a free incision. I then ordered the parts to be dressed once daily and oiled well to protect the skin. In eight or ten days the dead mass dropped off and the stump healed kindly without any further trouble.

"The boy is now four years old, and is stout and hardy, and well developed. Whether operating at once had anything to do with the cure I am unable to say. But suffice it to say, if another case of 'spina bifida' falls into my hands, I shall not hesitate to repeat that which gave such happy results. If an operation is intended, why not perform it immediately?"

THE HAHNEMANN MEDICAL COLLEGE, OF CHICAGO, has been solemnly rebuked by the State Board of Health for conferring degrees upon persons who have not actually attended upon two courses of lectures at least six months apart. The College Faculty deploras its past, and promises a more conscientious future.—*Med. and Surg. Journ.*

ATROPINE IN OPIUM POISONING.—In a case of opium poisoning reported in *The Lancet*, atropine was given in doses, first of one-tenth of a grain, then, one hour later, one-quarter of a grain. The patient recovered, but as various other measures of stimulation were used, the recovery could not be laid to the atropine. The case showed, however, that Dr. John Harley is not correct in saying that all doses of atropine larger than one-ninety-sixth of a grain are depressing and injurious.

LACHRYMAL CATARRH.

A CLINICAL LECTURE DELIVERED AT THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

By D. B. ST. JOHN ROOSA, M.D.,

PROFESSOR OF OPHTHALMOLOGY.

(Reported for THE MEDICAL RECORD.)

GENTLEMEN:—When a man or a woman gets a cold in the head it is spoken of and thought of as a very trivial affection. In the ordinary course of events I have no quarrel to make with that statement. But, after all, a cold in the head is a fruitful source of very serious evils. The person who keeps himself, or herself, in such a condition that he or she frequently has cold in the head, is safe from a great many dangers. The style of argument indulged in, in order to show that there is no danger from doing this or that dangerous thing, exposing one's self to this or that dangerous influence, is about as logical as if a soldier were to say that there is no danger upon the field of battle because he had never been shot. Thus people will tell you that they have colds in the head, have them in the summer and in the winter and at various times; sometimes, as they think, the result of imprudence, sometimes they hardly know why, and that they have never suffered from any specially evil consequences. A great deal of such statements rests upon *inexact observation*. For example, a great many people think they see perfectly, when their vision is only one-half what it should be. Again, I have very frequently seen persons who thought they heard well, when they were unable to hear ordinary conversation unless the person addressing them was near, and spoke with great distinctness. So that many of the statements about no harm having come to them rest upon *inexact observations*. Yet a great many people go through life without suffering from serious disease, frequently have a cold in the head, and die octogenarians. I grant all that, and yet, at the very outset of what I am about to say with regard to this case of double lachrymal catarrh, I will tell you that I am to lay great stress upon the etiological factor termed getting cold, and I shall attempt to show you that it is the source of most of the lachrymal catarrh with which we have to deal. I saw this patient for the first time yesterday, and the surgical operation which I then performed has so improved her appearance that you cannot have a full idea of how she looked at that time. Her eyelids were very much reddened along the margin—the ciliary margin—a term which I dislike because it is liable to be confounded with the ciliary region of the eyeball—and there was adhering to them a large quantity of dried secretion. In the corners of the eyes there was the same appearance which is now presented. In addition, there was a tumor upon the right side, over the lachrymal sac, and the eyes were overflowing with tears. These are the symptoms of chronic lachrymal catarrh. What I then did for her was to slit up the little canal which you all know passes from the lower eyelid into the nasal duct. You can easily see the punctate opening of that canal in the healthy eyelid by drawing the eyelid down, and there will be no excuse if you do not know *exactly* where that punctum is from this day on. I introduced vertically a deli-

cate probe-pointed knife, such as you here see, into the punctum, and slit the canaliculus well up into the lachrymal sac. I had much difficulty in getting into the lachrymal sac, because the disease had gone on to such an extent that it had dilated the walls of the sac; it had encroached upon the lachrymal bone beneath, and produced caries. I had difficulty in finding the opening into the nasal duct upon both sides; indeed, I did not find it upon one side on account of the large amount of carious bone.

Now let us hear her own story. She is thirty years old, and married. She says that when a small girl she had some trouble with her left eye, and recollects that there was an almost constant running of tears from it. The present trouble, and that which has given her more marked inconvenience, has existed about four or five years. There is free overflow of tears whenever she uses her eyes closely in sewing or other work, or reading, and especially when they are exposed to the wind. It is usually the fact, in connection with this trouble in the eye, that the overflow of tears is much greater when the organ is exposed to the wind than when exercised at work, even when considerable strain upon the accommodation is produced. There are many persons who have lachrymal catarrh that does not give them much inconvenience so long as they remain in the house, but the moment they go out into the air it becomes very troublesome. But in this case, it appears, it was troublesome both in the house and in the air, and, therefore, a well-grounded case of lachrymal catarrh.

Sometimes the general practitioner may mistake lachrymal catarrh for conjunctivitis, and it is very important that this error should not be fallen into, for you may treat lachrymal catarrh by the use of astringents from now until all your patience and patients are exhausted, and you will never cure it. The astringent will not get into the punctum or into the canaliculus; it will not go where it is needed; it will not do any good; and no man is justified in giving an astringent prescription for lachrymal catarrh. You might as well rub the astringent upon the outside of the cheek as to place it in the eye, for the opening is not large enough to allow it to enter the canaliculus in any sufficient quantity. Besides, there is usually stricture of the canal, there is always considerable swelling, and an astringent solution cannot enter in sufficient quantity to be of any radical service whatever.

When a patient comes to you with lachrymal catarrh, and you are sure of your diagnosis, and yet do not feel competent to either probe the puncta or slit the canaliculus and introduce a probe into the nasal duct, do nothing, but tell your patient that there is an imperative necessity for an operation which you do not feel competent to perform, if radical benefit is to be obtained. But how are you to tell whether the case is one of conjunctivitis or of lachrymal catarrh? I remember the great Von Graefe had a habit which all of us would do well to imitate, and that was, whenever a patient with red eyes sat in front of him, he at once put his thumbs over the lachrymal sacs and pressed upon them, to see whether or not muco-pus could be made to pass from the puncta. If it did, he immediately knew that, whatever else there was, lachrymal catarrh existed. Not that there was no lachrymal catarrh when he was not able to do that, for a patient may have emptied the sac and canaliculi, from force of habit just before entering the room; at all events, the important questions to be decided in every case of conjunctivitis are, the condition of the punctum, the canaliculus,

the sac, and the nasal duct. This is not a disease of the manufactory of the tears, but a disease of the conducting apparatus through which they are transmitted from the eye to the nose. If by pressure upon the lachrymal sac you can satisfy yourself in relation to diagnosis, very well; but, if you cannot, make a close examination of the conjunctiva, and see whether or not it is reddened throughout its entire extent—whether or not it is slightly more intense toward the lachrymal passages, and also look carefully at the edges of the eyelids. In this manner you will soon be able to satisfy yourselves as to whether the patient is probably suffering from lachrymal catarrh. So much stress has been laid upon this subject, that at the last meeting of the ophthalmologists of this country a paper was read upon lachrymal conjunctivitis, the writer supposing that even experienced oculists might sometimes make the mistake and diagnose conjunctivitis when they should have diagnosed lachrymal catarrh. It is therefore worth your while, as general practitioners, to be upon your guard against such a mistake.

I did not give this patient an anæsthetic, and she suffered considerable pain; but she has exhibited her confidence in the treatment by coming here to-day and allowing us to examine her eyes. Let us return for a few moments to the history of her case. She says that after suffering for a short time, when a small girl, she entirely recovered from the trouble in her left eye. Some three or four years ago the trouble reappeared, but we do not obtain any history of its having been excited by cold in the head, and indeed the only apparent cause we succeed in reaching is the fact that she was just then taxing her eyes severely upon fine sewing.

I will now return to my starting-point, and will give my opinion regarding the origin of lachrymal catarrh. I believe that it originates chiefly in naso-pharyngeal catarrh, and I believe that naso-pharyngeal catarrh originates chiefly in persons who are not very vigorous, and who live under improper hygienic conditions, and in persons tolerably strong, but who also live under improper hygienic conditions. No person in a physiological state of health, unless exposed to extraordinary influences and severe changes of temperature, will get naso-pharyngeal catarrh. Let me name over, as my memory suggests, the kind of people who have naso-pharyngeal catarrh. Any person whose system is tainted with syphilis is liable to naso-pharyngeal catarrh upon the slightest provocation. For, you must not forget that syphilis is a blood-poison, and it is also a disease which may be excited into action by improper hygienic conditions, and often by slight exposures. A man working in a damp cellar, for instance, who has syphilis in his system, may have a sudden outbreak of symptoms indicating the development of gummy tumor or syphilitic deposit at the base of the brain, about the auditory nerves, or along the origin of the third pair; the provocation being the exposure to cold while at work. This is the reason why the practitioner should look upon syphilis as a disease that may manifest itself in any part of the body, and should take great pains with regard to the general condition and surroundings of his patient. The reason why many get well of syphilis without much special treatment is found in the fact that they have abundance of good food and live under proper conditions after the poison enters the system.

Again, little children who are improperly fed and clothed, and perhaps inherit a consumptive diathesis,

get naso-pharyngeal catarrh upon the slightest provocation.

Again, those people who live improperly with reference to food and drink are very liable to this affection. The man who drinks a great deal of alcohol necessarily does not care for much solid and nutritious food, and in consequence his system becomes depreciated, and he is apt to get naso-pharyngeal catarrh.

Again, the class of persons who live and work indoors most of the time, who do not get a proper amount of physical exercise, who do not bathe themselves sufficiently with cold or lukewarm water and groom themselves properly—whose skin does not react quickly after sudden exposure, those people are very frequently suffering from naso-pharyngeal catarrh. You scarcely ever, probably never, hear of an athlete, or a country gentleman who superintends his own farm, and at the same time taking the greatest personal care of his general condition, having naso-pharyngeal catarrh.

The fundamental thing is to have a sound body by all the rules which you or I can or do learn. After I was away from maternal care I was not brought up to take a cold bath daily, but I soon began to appreciate what it will do for a man slightly built and obliged to live indoors a large part of the time. Since I have seen what attention to the skin has done for me and can do for others, I never can sufficiently impress upon medical students that, under ordinary circumstances, the natural condition of every human being demands that he should have his skin well groomed every day. Not with much soap necessarily, nor necessarily with a large quantity of water, but he should be well rubbed in order that his skin may be kept in a proper condition. I am confident that a great deal of lachrymal catarrh can be avoided in that manner. In some cases, however, the disease advances from the other direction, and a conjunctivitis goes on until it develops a lachrymal catarrh. The same remarks which I have made regarding naso-pharyngeal catarrh are to a certain extent applicable to conjunctivitis; not so much, however, for, as I have already told you, a man may get conjunctivitis from overworking the eyes, or from exposure to wind and dust when he is in a good condition of health.

How shall we treat these cases when they have the condition which was present in this woman's case yesterday. She is anæmic. I might have said to her, you had better go home, take cod-liver oil, iron, etc., and do so and so, all of which would be proper for a patient in her condition; but all that would not cure her lachrymal catarrh. The surgeon must interfere. A condition has been reached which cannot be cured by general medication. There must be positive dilatation of these parts; these obstructed passages must be so relieved that they can carry off the natural secretion. That is done by a simple procedure, which I propose to do before you as far as possible. The history of the steps which have led us to this procedure is very interesting. The old style of treatment was to cut into the lachrymal sac from the outside, introduce a probe or canula, and leave it permanently. In that manner a permanent disfigurement was caused, which, particularly in females, was regarded as so great that many of them preferred to suffer the lachrymal catarrh rather than to submit to such a permanent blemish. Besides all that, it did not cure the people in probably more than fifty per cent. of the cases. No longer ago than sixteen years, when I was house-surgeon in the New York Hospital, it was the general opinion there that treatment of lachrymal

catarrh was one of the opprobriums of the profession. I do not say that such was the advanced opinion, for probably at the Eye and Ear Infirmary at that time the surgeons were treating the disease rationally. But if we go back as far as twenty-five years, I think a period will be reached when the treatment of lachrymal catarrh was pre-eminently unsatisfactory among all kinds of surgeons. At the present time my individual experience is such as leads me to believe that it is pre-eminently satisfactory. There are certain cases that come to my office which I dread to meet. But I am always glad to see a patient enter who has lachrymal catarrh, because I feel more or less sure that I can do a great deal, except in extraordinary instances, to relieve his condition. I think that something has already been done for this woman in the last twenty-four hours by the surgical operation which I performed yesterday. It is an operation which every one of you who is fit to open an abscess can learn to perform.

How was this method of treatment reached? Mr. Bowman, of London, the physiologist of former days, suggested that the canaliculi be opened, that it be converted into an open canal. He did that with scissors, having first probed it, and then passed a probe into the nasal duct. We now use a knife to open the canaliculus, and we do not resort to the preparatory probing in the ordinary cases. Yet, the principle which Mr. Bowman enunciated is still carried out in all places where ophthalmic disease is treated according to the advanced opinions of the nineteenth century. You will hear of Stilling's method of cutting through the stricture, and you will hear of destroying the lachrymal sac and other procedures which become necessary; but it is my conviction that in a very large percentage of cases—so large as to render the others completely exceptional—you will do very well if you learn to dilate the canaliculus and probe the nasal duct. If you will patiently and persistently treat cases in that way, you will get very good results indeed. Children should be put under the influence of ether before the operation of slitting the canaliculus is performed; but you may learn to probe children's eyes without an anæsthetic. Lachrymal catarrh in children is usually recovered from very rapidly. One probing is frequently sufficient in very young children to effect a cure of a mild case of lachrymal catarrh.

It will be observed that I have not said anything about lachrymal abscess or concerning the formation of lachrymal fistula. These are the consequences of lachrymal catarrh; they are the second stage in the inflammatory process, exactly as purulent conjunctivitis is the second or third stage of catarrhal conjunctivitis, and the treatment is essentially the same as in the catarrh. Get the passages into such a condition that nature can do the work of carrying off the tears, and the abscess will take care of itself. I would like to speak of acute lachrymal abscess, but my time is now too limited. I will simply say that you must be upon your guard lest you consider acute lachrymal abscess, supervening upon a natural catarrh, as it usually does supervene—you must be careful, I say, lest you regard it as a case of facial erysipelas, and proceed with local applications, such as lead and opium, or, with constitutional ones, iron, and so forth. Please to remember that the history of the case is an important factor in diagnosis in those instances, and you should determine whether or not the patient has had a weeping eye for some time previous to the acute attack—for there will be no lachrymation when the parts are greatly swelled—and you can usually make a correct diagnosis.

[The patient was then placed in position, and Bowman's probes were introduced into the nasal duct.]

So much dilatation has been made by the progress of the disease, that probe No. 5 can be introduced quite readily. I introduce it first vertically, then horizontally, and then again vertically, and as you see it is now in the nasal duct.

In the left eye I yesterday reached a carious cavity, but did not succeed in passing the probe into the nasal duct; but I have now reached the duct, the probe has entered it, and the patient is in the condition of being treated. These probes may remain in from ten to thirty minutes, and I do not think much is to be gained by allowing them to remain longer at any single sitting. The principle of treatment is dilatation of a canal whose calibre is filled by a swollen mucous membrane. The gentlemen at the hospital often ask, "How much force do you use in introducing the probe into the nasal duct?" It is impossible to answer that question. I cannot answer that question any more than I can by words teach a man how deep to cut in order to get into an abscess. It requires the *tactus eruditus* of which the ancients spoke so much. It is simply a matter of experience, and it is in that way only that you will learn how much force to employ. The only principle I bear in mind in probing these passages is to be sure that my probe is in the canal, and then I use as much force as is necessary to go through. It all resolves itself into the advice given by David Crockett: "Be sure you are right, and then go ahead." Be sure your probe is in the nasal duct, and then go ahead. The canal is not like the urethra. If you have had experience in sounding the urethra, you know there is no care which should not be exercised, nothing which you can neglect unless at the expense of safety. But in this instance you have a different condition of things. You are here dealing with a bony canal, except as to the outer side, and if your probe is once in that canal you can go on with comparative safety. Now and then, I know, we treat stricture of the urethra differently; but if you propose to treat such strictures by gradual dilatation, you know you must be very careful with reference to the exact course in which your instrument is moving.

One point further. How many of these cases go about without treatment! A case of lachrymal catarrh which has persisted for weeks or months should be treated, not only for the present relief, but also to prevent the formation of lachrymal abscess, which is extremely painful, and which may lead to very considerable personal inconvenience, not only to the physician, but to the person suffering from it. Therefore I say, that if you feel sure you have a case of lachrymal catarrh, and it is established that it is not a case in which the condition will pass away within a few days, treat it, and by the method just described.

WOMEN IN HARVARD MEDICAL SCHOOL.—A meeting of the Board of Overseers of Harvard University was held some time ago to decide as to whether they should accept a bequest of ten thousand dollars on condition that women be allowed admission to the medical school. It was voted to decline this proposition. At a subsequent meeting, however, a resolution was passed asserting that, under suitable restrictions, it would be expedient to allow women to be instructed in the medical school. Harvard is thus put on record both for and against the medical co-education of the sexes.

A CASE OF OSSEOUS TUMOR IN RIGHT ORBITAL CAVITY SUCCESSFULLY REMOVED, WITH PRESERVATION OF THE SIGHT.

By VAN S. LINDSLEY, M.D.,

PROFESSOR OF PHYSIOLOGY AND DISEASES OF THE EYE AND EAR,
UNIVERSITY OF NASHVILLE AND VANDERBILT UNIVERSITY,
NASHVILLE, TENNESSEE.

MR. BILLS, of Verona, Marshall Co., Tennessee, consulted me last February about his eye. I found exophthalmos of the right eye existing to a very marked extent, the left being normal. Two years ago he noticed that the eye seemed more prominent than the left, and some months afterward he suffered intense pain behind the globe, which continued for, as he expressed it, "one hundred hours." During the pain a swelling occurred at the upper and inner side of the orbital cavity, and finally broke, emitting matter. The pain then ceased and swelling apparently receded. Again, in a few months, his friends noticed that the eye was getting prominent. It has been steadily and gradually pushed forward up to the present time, May 1, 1879, and presents the following appearance and condition:

The exophthalmos is very great, the ball being pushed beyond the circumorbital ridge, so that the lids do not entirely cover it. The cornea is bright and healthy, and also the general conjunctival covering, except the lower half, which is redundant and highly congested. At the junction of the roof and inner side of the orbital cavity there can be seen and felt a distinct nodular swelling about the size of a forefinger knuckle. When traced as far as the finger can explore, it is found to pass back far into the orbit behind the ball, and to become larger as it goes. The skin is loose over the tumor, and, excepting some enlarged veins, healthy.

The sight of the eye is good, considering the amount of tension and pressure so long exerted on the optic nerve. The patient says it is as good as that of the other eye, but on examination I found he could only read No. 12 Jaeger's types, for distance Snelling's No. 40.

The movements of the eyeball are somewhat impeded, and he sees double only at certain times.

Dr. Nowling, now of this city, and formerly of Marshall County, having been Mr. Bill's family physician, was consulted also in reference to the case. After examining the case carefully we determined on an operation for removing the tumor, which was accordingly done, with the assistance of Drs. Nowling, Drake, Rogers, and Sharber, of Columbia. Ether was selected as the anesthetic, and Squibbs' preparation used freely and faithfully for one hour and fifteen minutes, without producing the proper effect. There being no prospect, apparently, of securing anesthesia by this mode, chloroform was substituted, and soon the patient was breathing stertorously after inhaling about one drachm.

An incision was made with scalpel in the crease of the upper lid, commencing at the inner upper orbital angle about half an inch long and over the tumor. After the division of the various layers down to the tumor, the finger was passed down, separating the tumor from the eyeball and surrounding parts, and tracing it back as far as the upper border of sphenoidal fis-

sure, where it seemed to have its original attachment. The neoplasm was so firmly attached to the periosteum of the orbital roof, that the periosteum had to be ruptured and peeled back in order to force it from its upper attachments. It was found now that the neoplasm was far too large to be removed through the opening already made in the lid, so that by means of an ordinary steel elevator and the finger, I ruptured the tumor and removed the anterior half by piecemeal. The remaining portion was cut loose from its attachment to the bones by means of long curved scissors. The bleeding was very profuse, and although there had necessarily to be considerable pressure on the ball, the muscles and optic nerve were preserved intact.

A few minutes after removal of the tumor the eye was easily replaced in its natural position, but soon afterward such swelling took place as to cause the eye to protrude worse than ever, and the only way we could repress it was to put several stitches in the margins of the lids. This, with a well applied roller-bandage, held the eye in place and controlled the swelling.

After a few days the stitches were removed from the lids and the ball found to be movable, free from inflammation, and sight as good as before operation. The wound through which the tumor was removed healed by first intention and gave no further trouble. The patient has written since returning home that the eye continues to improve.

The tumor we found to be of an elongated form antero-posteriorly, and compressed above and below by the eyeball and roof of the orbit. It consisted of a strong investing membrane resembling periosteum both in texture and strength, and was loosely connected with its surroundings excepting the roof of the orbit, where the periosteum and membrane of the tumor seemed continuous, or one and the same. The interior of the tumor was a friable cancellated bony tissue, which was capable, as stated before, of being broken to pieces by the elevator, used in removing parts of the growth. Bone tumors occur occasionally in the orbit as outgrowths from some portion of the lining periosteum, and may be either of the spongy character as related above, or of the hard eburnated kind.

REPORT OF A CASE OF HYDROPHOBIA (RABIES) SUCCESSFULLY TREATED WITH CURARE.

By DR. AD. OFFENBERG,

WICKRATH (RHEINPREUSSEN.)

(Translated by S. W. WILLIAMS, M.D., Bellevue Hospital.)

ANNA HEITMANN, a servant-girl in the employ of a peasant named Hense, while passing the yard of one Jürgens, a neighbor, on the 28th of July, 1874, was bitten in the left heel, through the stocking, by a spitz dog.

The dog had been, during fourteen days, chained near the highway, for the protection of linen which was bleaching in the yard. The girl was in the habit of passing the house several times daily, and had won the friendship of the dog by throwing to him pieces of bread. It seemed strange, under these circumstances, that the animal should have bitten her without the slightest provocation.

Overlooking the account given by the servant-girl of the subsequent behavior of the dog as possibly exaggerated, we have the statement of the owner, supported by several neighbors, that the dog was not

naturally ugly; that upon the same forenoon, and shortly after he had bitten Anna H., he was seen to be very uneasy and to run round in circles as wide as his chain would permit. He pulled at and bit the chain, and was constantly springing up against the neighboring wash-house. At mid-day, the condition of the dog being much worse, the owner sent for a veterinary surgeon, who, upon the mere statement of the animal's condition, pronounced him to be mad, and advised that he be immediately shot.

This unusual and striking behavior of the dog raises the strongest suspicions of hydrophobia—a suspicion which is justified by the fact that, in the summer of 1874, the village was repeatedly thrown into excitement concerning dogs that were either suspected of being mad or were so in reality. In the very beginning of the summer a strange dog, showing signs of hydrophobia, had wandered about the place, and had bitten a number of other dogs, which were straightway killed by order of the police. At the end of June the dog of Wessels (a peasant of the place) grew sick and restless, ate nothing, wandered about in the neighborhood, bit some of the cattle and several of the residents of the farm. Schuller Wessels, a man thirty-four years of age and proprietor of the estate, was bitten in the right hand. The dog was caught and confined, and a few days later died. The veterinary surgeon who made the autopsy pronounced the death of the dog to have been the result of hydrophobia.

Wessels was persuaded by the surgeon to have the wound in his hand cauterized with nitrate of silver, and to take for several days, as a prophylactic, a remedy the composition of which was unknown. When Wessels learned that Jürgens's dog had bitten Anna Heitmann, he determined to procure for her the remedy by means of which he believed himself to have been secured against all danger of an attack of hydrophobia. On the 29th of July, while writing a letter for this purpose, he was taken suddenly very ill, and was unable to finish the letter. From this time the signs of hydrophobia went on developing, and he died early upon the morning of July 31st.

A few days later it was found necessary to kill a jackass belonging to Wessels's farm. He had been bitten by the same dog, and had grown very uneasy, and disposed to bite every one who came in his way. He was especially inclined to bite the calves.

In view of the facts now stated, there seems to be no doubt but that Wessels's dog was suffering from hydrophobia; and, since the courtyards of the two men—Wessels and Jürgens—were separated by only about 300 paces, it is altogether probable that Jürgens's dog, four weeks before his sickness, came in collision with the other dog as he was wandering about, and was by him bitten and infected.

As already mentioned, Wessels was taken sick on the 29th of July—that is, upon the day after Anna H. was bitten. Upon the 30th of July the two physicians of the neighborhood, Drs. Hölker and Wilkinghoff, attended Wessels at his house. Anna Heitmann availed herself of this opportunity to consult them in regard to her own injury. When it became known that the master of the house was suffering from hydrophobia, the servants were thrown into the greatest consternation, and many of them immediately left; thereupon Anna H. consented to remain for a while and assist in the housework. She was thus a witness of the severe convulsions and delirium of the sick man, and also of his death.

On the 30th of July, two days after the servant-girl had been bitten, Dr. W. found upon her left foot,

between the tendo-Achillis and outer malleolus, an excoriated place about the size of a ten-cent piece, of a reddish, bloody appearance, from which oozed a reddish fluid. The doctor ordered a warm foot-bath for the purpose of cleansing the wound, which had thus far received no treatment beyond simple dressing with a piece of linen. He also prescribed a concentrated solution of caustic potash, and directed that with this the girl should herself cauterize the wound.

The apothecary was at a considerable distance, so it was not until the lapse of several hours that she was able to apply the caustic. This she did in the following way: having soaked a piece of linen in the solution, she laid it repeatedly upon the region of the wound, in this way producing on the outer side of the foot a deep eschar almost as large as the hand.

A few days later she tried a course of treatment very highly esteemed in that region as a preventive to the outbreak of hydrophobia. The treatment consisted in going twenty-four hours without food, drink or sleep, and at the same time taking a mixture composed chiefly of a concentrated solution of chloride of sodium, to which were added certain acid juices of plants. According to the statement of the patient, her mouth and throat were sore when she began to use this remedy, and the acrid fluid therefore caused severe burning pain. The girl said her tongue was swollen so that she could scarcely move it, and that the acts of speaking and swallowing were attended with great pain. Since all attempts to drink caused great distress, she objected to taking the proffered medicine, and gave expression to her aversion by gestures. The people of the house, who had grown timid and suspicious on account of the recent death of their neighbor, thought the actions of the servant-girl betokened dread of water and convulsions, and sent for the nearest doctor, in the belief that hydrophobia was already developed. The true state of the case remained unknown to the doctor, since the patient could not make herself understood, and the inmates of the house, intentionally or unintentionally, remained silent concerning the remedy which the girl had been taking. Dr. Hölker, who did not make a careful examination of the mouth and throat, saw in her actions only signs of dysphagia and convulsions. These appeared whenever she attempted to drink. The doctor prescribed for her a preparation of morphia. Four or five days later all these unpleasant symptoms and the gastritis, which had existed at the same time, had completely disappeared. The girl was very nervous in regard to her condition, and returned to her home. The wound upon her foot was at first treated with carbolic acid in solution, and then with basilicon ointment, since Dr. W. proposed to keep it suppurating for at least three months. This mode of treatment, however, was incomprehensible to the pastor of the place. He declared the physician a quack, and, fearing lest the girl should lose her foot, and in order that she might come under more "intelligent" treatment, brought about her reception on the 8th of October, into the Franziskus Hospital, in Münster, i. W.

Anna Heitmann, unmarried, 24 years of age, comes of a peasant family in the parish of Herbern. The nine grown-up brothers and sisters and the parents enjoy the best of physical and mental health. No disease of the nervous system was ever known in the family. She herself has never been seriously sick. The catamenia began in her fifteenth year, and although, during the last year and a half, more abundant and more frequent than formerly, they have run

their course without any difficulty worthy of mention. She is a well-nourished, strongly built person, and appears to be in vigorous health. Her educational acquirements are below the average for persons of her condition in life. She displays a clear mind and good disposition, and her genial manner obtains for her the good-will of all who come in contact with her. She says she is in constant dread of the outbreak of hydrophobia, and that by thinking so much about the disease which threatens her, she is frequently startled from her sleep at night.

On the outside of the left foot, extending from the tendo-Achillis over the dorsum, is a reddish granulating wound surface about the size of the palm of the hand. Here and there the edges are undergoing cicatrization, and near the borders of the wound are a few pustules and superficial ulcerations. On account of the size of the wound it was considered unadvisable to continue the use of irritating applications; and by the 16th of October, under a simple dressing, the granulating surface had become much smaller. On the 10th of October the menstrual flow began; it was not accompanied by any disturbance of the general health, and by the 16th of October it had nearly ceased. She passed the 16th of October in her usual way; was up and about the ward most of the time; neither by the physician, nurses, or neighboring patients was any change observed in her manner until evening. At 6 p.m. she ate her supper with a fair appetite; about seven o'clock she seemed rather nervous; a jesting remark, intended to soothe her, not only failed of its purpose, but also caused her to cry, although, as she herself later admitted, there was no sufficient reason for this in what had been said. The other patients of the ward were astonished at her behavior, and rebuked her for it. In addition to this abnormal sensitiveness she was suddenly seized, about 8 p.m., with an attack of dyspnoea, directly caused by an attempt to drink. She was unable to swallow any of the water, and now convulsions followed one another in quick succession. At their first appearance it was inferred that the patient was suffering from hydrophobia, and this suspicion being confirmed by nurses who had already seen cases of hydrophobia, she was at once isolated from the other inmates of the ward. I reached the patient at 10.45 p.m. She suffers from extreme uneasiness and anxiety; cries and moans constantly; is fully convinced that she has hydrophobia, and that there is no hope of recovery. She complains of pain in the upper mammary and anterior cervical regions, especially severe in the region of the larynx and of the hyoid bone; pressure at these places seems to increase the pain. She also has severe pain in the throat, yet nothing abnormal can be seen—neither redness nor swelling. In making the venturesome experiment of inserting my index-finger deeply down her throat, I observed a marked decrease of sensitiveness in the soft parts, for, when I irritated these parts with my finger, no reflex movements were aroused. The secretion of saliva is not increased. There are no vesicles of Marochetti under the tongue. The temperature of the body is only slightly raised. Not the slightest change can be detected in the wound on her foot, yet she sometimes has pain in it which extends as high as the knee. Extreme muscular restlessness pervades the whole body; the muscles of the extremities especially are the site of slight unremitting convulsive movements. The pulse at the wrist cannot be counted, owing to the jumping of the flexor tendons. At intervals of one or two minutes occur inspiratory spasms and general clonic convulsions. These spasms are ushered in by

short, groaning sounds, produced by the forcible passage of air through the narrowed glottis. The chest, at the same time, assumes the position of inspiration and becomes more fully expanded; the shoulders are drawn upward, the head backward; the sterno-cleido-mastoid muscles stand out as thick and firm bands; other muscles of the neck are quite prominent. The thorax remains fixed in the position of inspiration for ten or fifteen seconds, during which time the rest of the body is in a state of severe clonic convulsions; the arms are tossed wildly about, or are fastened convulsively upon the proffered hand. During these convulsions she suffers from great dyspnoea; constriction in the breast; a feeling as though the larynx were drawn together; there is also pain in all the limbs.

If the convulsion remits a little, the breathing, at first superficial and rapid, becomes more quiet. A short time before a convulsive attack begins, she is warned of its approach by an increase of her uneasiness. Every attempt to drink arouses a feeling of constriction in the throat, and it is only with the greatest effort that she is able to swallow a little fluid, and these attempts to swallow are always followed, in a few seconds, by an inspiratory spasm.

10.30 P.M.—Subcutaneous injection of 0.02 (gr. $\frac{1}{2}$) morphia, and inhalation of chloroform.

10.45 P.M.—Within the last half-hour the patient's condition has in so far grown worse that the above-mentioned convulsive attacks are more severe and frequent, that great photophobia has developed, and that the symptoms of real hydrophobia now exist. Her thirst is extreme. She is now utterly unable to drink; heretofore she has been generally able, although with the greatest effort, to swallow a little liquid. As the glass touched her lips she trembled, stared confusedly around, and, having been raised up that she might more easily drink, threw herself back with great force upon the bed. This difficulty in drinking she attributed to the odor of the fruit-juice that had been mixed with the water; but the same symptoms were aroused by every attempt to drink clear water. Indeed, the mere approach of the glass to her mouth caused her to shudder, and called forth gestures of the strongest opposition. Generally, every such attempt was followed immediately by a severe convulsion.

During the intervals the anxiety and precordial uneasiness had markedly increased. She requested to have the prayer* of the death-bed read to her.

After one very severe and painful attack she cried aloud for different members of her family, and asked bewildered, "Where am I?"

The injection of morphia had exerted no sedative influence; on the other hand, the disease had grown worse. The dose of morphia was therefore not repeated. The inhalation of chloroform, carried to the point of stupefaction, gave great relief, yet each time the anæsthetic was thus used it seemed to me that the next respiratory effort aroused a fresh attack of convulsions.

Considering the diagnosis of hydrophobia established, I believed there should be no further delay in using curare. There happened to be in the hospital a solution of this drug 0.5 : 10.0 aq. dest. filtered (gr. $\frac{7}{8}$: 3 ijss.).

I had proved the effectiveness of this solution not only upon frogs, but also a year previously in two cases of traumatic tetanus. These cases ended fatally, but the observations then made urge to an active use

* Sterbegebet.

of this poison. In the first case 0.002 to 0.02 (gr. $\frac{1}{32}$ to $\frac{1}{8}$), curare was injected at intervals of five hours without the slightest apparent effect. In the second case 0.015 to 0.06 (gr. $\frac{1}{16}$ to $\frac{1}{8}$) curare was injected at intervals of three or four hours. After the last dose of 0.06 there was a brief relaxation of the tetanic symptoms.

Having now determined upon the use of curare, at 10.45 P.M., about three hours after the sudden outbreak of the attack, 0.02 (gr. $\frac{1}{8}$) curare was hypodermically injected; fifteen minutes later, there having been no appreciable effect, the dose was repeated. The general muscular tremor, which had existed all along during the intervals between the convulsions, became gradually less, and finally almost disappeared. The pulse at the wrist was now easily felt and counted. It was generally 80 or 90 beats per minute; after a convulsion 100 to 104; beyond this there was nothing remarkable about it.

12 P.M.—The intensity of the respiratory spasms continues the same, but the duration of the intervals between them seems to increase. The intervals average about two minutes in length.

The photophobia is intense. The patient says, when she sees the flame of a candle it seems as though she were looking directly at the unclouded sun. Notwithstanding that all bright light was kept away by means of screens, she said the light was too bright. Even after all lights had been removed she complained bitterly if a ray of light reached the darkened room through the open door.

The auditory sense seemed very acute; words spoken in the neighboring room, intentionally in a low voice, which one would not have thought it possible for her to hear, she fully understood.

Repeated efforts to drink were not only unsuccessful, but caused severe convulsive attacks.

12 P.M.—Subcutaneous injection of 0.03 (gr. $\frac{6}{13}$) curare. The hypodermic injections were dreaded by the patient on account of the pain caused by the puncture; but she was easily persuaded to allow it to be done. It became more and more evident that the pauses between the convulsions were increasing in length. She now complained of severe lancinating headache, which was alleviated by cold compresses.

October 17th, 1 A.M., 0.03 (gr. $\frac{6}{13}$) curare was injected. The intervals between the convulsions are longer, extending to five minutes; the convulsions, however, are as severe as before. Her anxiety and uneasiness is much less intense. She herself perceives the improvement in her condition, and no longer refuses to believe that there is hope of recovery.

2 A.M.—0.03 (gr. $\frac{6}{13}$) curare injected subcutaneously. During the intervals between the convulsions the patient feels tolerably well, complains only of headache. She is less irritable and emotional. The sensation of constriction in the chest has disappeared. The pain in the throat and neck is much less severe. She is cheerful, and thinks that she will completely recover.

2.30 A.M.—0.03 (gr. $\frac{6}{13}$) curare injected. She is unable to swallow pieces of ice, and every attempt to do so is immediately followed by a severe convulsion. The intervals are now sometimes ten minutes long. She is remarkably communicative, indeed, loquacious. She gives long accounts of her early life. She told in a sprightly tone how she had cured herself and other persons of scabies by a salve which she prepared from fat oil and snuff. She joked about her own condition, and, if interrupted by a convulsion, would pick up the conversation when it had passed and go on in the same lively manner. Urged by her great thirst,

she was always anxious to make one more attempt to drink, and was always unsuccessful.

3.10 A.M.—No convulsion having occurred during the last fifteen minutes, one was observed, which in severity and duration, was much less severe than any that had previously occurred. Ten minutes later, in compliance with her earnest entreaty, a glass of water was given to her, but it had scarcely touched her lips before she shuddered and passed into a severe convulsion.

3.20 A.M.—0.03 (gr. $\frac{6}{13}$) curare was injected. Shortly before this the patient had complained of a peculiar weakness in her right shoulder; immediately after the injection she said all her limbs were growing lame. Intense symptoms of paralysis were now very rapidly developed—within one minute. She was no longer able, unassisted, to raise herself in bed. She could not move the upper extremities at the shoulder or elbow, nor the lower at the hip or knee. Voluntary movement of the fingers and toes was possible only in a slight degree. Respiration was not involved. She continued to be cheerful and talkative. The extremities were rubbed with spir. sinapis, and compresses soaked in this were placed upon the throat and breast.

3.30 A.M.—A mild convulsion occurred, the thorax expanded as in the earlier attacks, but remained in this position only a few seconds; meanwhile there were slight spasmodic movements in the fingers, then respiration again became normal.

3.45 A.M.—There occurred a short, feeble convulsion which lasted but a few seconds. After it had passed, and she had breathed superficially a few times, the respiratory movements ceased altogether and without the occurrence of a convulsion. Respiration was, however, at once restored by strong pressure upon the abdomen and thorax.

4.15 A.M.—There occurred a short convulsion which seemed to have been cut short, and the patient thinks she arrested it by force of will. After this convulsion the same complete arrest of respiration occurred, and rhythmical compression made three or four times on the chest and abdomen sufficed to restore normal breathing.

At twenty-three minutes past four occurred the last convulsion that she had; it was scarcely more than an irregular convulsive inspiration. For several hours the paralytic phenomena continued, and extended to the organs of speech. The patient, who had been so talkative, could now answer questions only in a weak voice. Movement of the eyelids was difficult, and they opened and shut slowly. The respiratory movements now became weaker and more superficial, but were not interrupted.

When the extremities were touched, pressed upon, or moved, she felt severe pain. Especially painful were the places where the hypodermic needles had been inserted. There was still severe pain in the head and in the region of the larynx and hyoid bone; she could not move her limbs; there was no tendency to sleep. Toward 7 A.M. the skin became moist, and, by means of hot bottles and thick covering, profuse diaphoresis was induced.

7.30 A.M.—The paralytic phenomena having become somewhat less severe, she drank a glass of water without difficulty or bad results. From this time on she was able to drink whenever she desired to quench her thirst, which was extreme.

8 A.M.—The patient was carefully placed in a warm bath in which she remained ten minutes. The bath was well borne. The paralytic phenomena still continue in part.

About mid-day the paralysis became less marked, and during the afternoon disappeared almost entirely; a feeling of extreme weakness alone remained. The pain in the head and the sensitiveness of the arm continued. The tissues immediately surrounding the places where the hypodermic needle had been inserted were swollen and painful on pressure.

At noon the temperature was 38.6° C. (101½° F.); in the evening, 38.3° C. (101° F.); pulse, 84; moist skin; moderate thirst. No difficulty in speaking; state of mind more cheerful. At 6 P.M. there began to be noticed spasmodic twitchings of the muscles of the arms, at first isolated, later more general. The patient herself drew attention to the fact that immediately after drinking an involuntary spasmodic inspiration occurred; this phenomenon she intentionally reproduced several times. The chest now expanded, just as it had done in the mild convulsion on the preceding night, and remained several seconds in the position of inspiration. The muscular movements became more marked. There was a slight feeling of constriction in the chest.

At 9 P.M. these convulsive phenomena ceased, and she fell into a sound and quiet sleep, out of which she awoke at 1 A.M., October 18th, in a severe chill. This lasted three-quarters of an hour, and disappeared after she had taken some hot drink. She slept no more during the rest of the night. No further paralytic or convulsive phenomena were observed. Late on the morning of October 18th occasional convulsive movements were noticed in the muscles of the arm. Patient complained of headache and photophobia. About 11 o'clock, without any special cause having been discovered, she suddenly came into a condition of very complete paralysis, ushered in by a feeling of extreme weakness. She was scarcely able to move a finger. With the eyes shut or half open she lay there quiet and motionless. To questions, she either made no reply, or did so, hardly moving her lips, in a voice almost inaudible. Respiration was very superficial. Temperature, 38.1° C. (100½° F.); pulse quiet and normal; skin moist. She recognized relatives who came to see her, but was unable to talk with them. This paralytic condition, after continuing an hour with undiminished intensity, disappeared completely in the course of the afternoon.

Redness and swelling had become more widely extended on the dorsal side of both forearms, and the skin in the upper two-thirds seemed erysipelatously infiltrated. Similar infiltrations, about the size of a silver dollar, existed in the lower extremities at the points where the hypodermic needle had been inserted. The patient avoided, as far as possible, all movement of the body, and especially of the arms. She had taken pills of aloes and pulv. glycyrrh. comp., and toward evening there occurred free catharsis. Since noon there had been developed, in addition to the pain in the head and neck, pain also in the sacral and dorsal region.

About 7 P.M. the subsultus began again, at first isolated, soon more general and severe. Attempts to drink aroused afresh the inspiratory spasms. After nine o'clock these occurred at intervals of two or three minutes. The subsultus was more severe, and there was greater uneasiness, thirst, and photophobia. In order to prevent further unfavorable change in the patient's condition, 0.03 (gr. ⅓) curare was injected at 9.30 P.M., and it was ordered that, for the present, she should have nothing to drink. In fifteen minutes the effects of the curare were apparent. Her anxiety disappeared, she became once more cheerful and talkative; the subsultus ceased; the inspiratory spasms

occurred less frequently, and in the course of an hour disappeared entirely. At midnight, in compliance with her earnest request, she was given something to drink. An inspiratory spasm occurred; and, just as had happened on the forenoon of October 18th, was immediately followed by extreme paralysis of voluntary movements. Respiration was only slightly affected—it became a little less energetic. The paralysis continued for an hour with unabated intensity, and then disappeared.

In the early morning of October 19th the patient slept three hours; a little later she complained of headache, pain in the abdomen (aloes), and sensitiveness to bright light; temperature, 36.7° C. (98.06° F.); pulse, 80. Subsultus was occasionally observed during the forenoon. Twice after drinking there was spasmodic retching.

At 4 P.M. the paralysis, already several times observed, again occurred, and it was also upon this occasion ushered in by a convulsion, which was the result of fright caused by a heavy thunder-storm. Two hours later patient was again in the condition in which she had passed the forenoon.

8.30 P.M.—Temperature, 37.0° C. (98.6° F.); pulse, 70. Having slept quietly from this time till 1 A.M. she was seized with a chill, which lasted half an hour, and was marked by severe chattering of the teeth. During the next few hours spasmodic retching occurred repeatedly after drinking. From five till six she slept quietly.

The morning of the 20th brought no change in her condition. Headache and occasional convulsive movements still continued, except during two hours while the patient was sleeping. In the afternoon there was slight headache, but no muscular tremor. She declared herself to be better than she had been at any time during the last ten weeks. Having taken since the 16th nothing but water and occasionally a little wine, she now, October 20th, ate bread and milk with relish. She attempted to read from a prayer-book, but discovered that she was unable to make out a single word; the letters seemed to move about in circles. The superficial redness and swelling of the extremities due to the hypodermic injections is diminishing.

With the exception of a chill, which lasted about ten minutes, the patient slept quietly nearly the whole night of the 20th and 21st, and on the following day her condition was very satisfactory. There was no pain; no sick feeling; the appetite was good; she was cheerful; in short, she complained alone of general weakness; a certain sensitiveness of the eyes to bright light, and a scintillation of the letters before her eyes whenever she read.

In the afternoon she ventured to get up, but was compelled, after a few hours, by a severe headache, to return to bed; cold compresses applied to the head relieved the pain. On the night of the 21st and 22d she slept quietly five hours, until one o'clock, when she had a short chill. After the chill had passed she again went to sleep, and awoke in the morning with moderate headache, which disappeared during the afternoon; otherwise she felt quite well.

Isolated spasmodic movements were observed in the fingers and arms. In the evening she received gr. viij. quin. sulph. The night of the 22d and 23d, passed without a chill, but the patient was kept awake by coughing, having sat by an open window upon the previous day and taken cold.

On the 23d and 24th there were isolated convulsive movements, and slight headache. On the 26th, only headache. She had, however, to contend with

an acute catarrh of the respiratory tract. After the 28th the catarrh gradually decreased.

From this time on the patient seemed rapidly approaching complete recovery. Her complaints now had reference especially to the sensitiveness of the eyes to light, to diminished power of vision, and to a general feeling of weakness. The healing of the wound on the foot progressed favorably, and on the 28th the wound was about the size of a silver half dollar.

Nov. 4th.—Patient complains of pains in the dorsal and sacral regions, of a tired feeling, of uneasiness, and of loss of appetite. The menses set in on the next day, the flow was slight and lasted but a few hours.

24th.—Angina faucium has developed, and to-day the patient remained in bed from general indisposition.

26th.—The angina is diminishing, patient complains of sacral pains.

27th.—Slight indication of the menses.

Dec. 3d.—The wound on her foot is completely cicatrized, and, her general health being good, she was allowed to leave the hospital and return to her home.

19th.—Patient returned to the hospital. In general, she felt well, but her former health and strength was not fully restored. She moved about slowly and without energy. The eyelids were often only half raised, and their movements were slow. She said that to read was difficult for her and made her very tired; that she could not see by lamplight, and that bright light was disagreeable to her eyes.

In January, 1875, she entered once more upon the duties of servant-girl. Further improvement in her condition was very slow; she was somewhat anæmic. The menses stopped completely; fluor albus appeared, and it was not until six months later that the menses became regular again. Finally, only a slight fluor albus and a dull expression in the eyes remained. Although, when she left the hospital, her fear and anxiety in reference to hydrophobia had departed, they were again aroused by the thoughtless assertions of friends, that it was possible for the disease to relapse. Her unhappiness was still further increased by the fact that a young man, toward whom she entertained the tenderest feelings, was induced to cease his attentions through fear of a renewal of her malady.

In January, 1877, I received from her a letter informing me that she no longer felt any uneasiness, and that for several months past she had enjoyed the most perfect health.

A CASE OF OPIUM HABIT CURED BY GALVANISM.

By WILLIAM F. HUTCHINSON, M.D.,

PROVIDENCE, R. I.

ABOUT the first of January of the present year, I was requested by Dr. O. C. Wiggin, of this city, to see with him a lady supposed to be suffering with cerebral congestion in an advanced stage.

A visit to Mrs. S. revealed the following history: Age 39, married; one child æt. six, and has had one miscarriage. Weight, about 150 pounds, and general appearance of contour and skin good. Patient kept up a low moaning, answering most of my questions intelligently, then relapsing into a semi-unconscious condition. Pulse 100, compressible. Temperature 99°. No loss of control of evacuations. Conjunctive congested, and pupils contracted closely. Perspiration

starts upon the smallest exertion, which also causes pain in abdomen and excites vomiting, which has lately become persistent, accompanied with intense thirst. Hands and feet cold, with shrivelled palms and plantar surfaces. No difference in temperature of head and axilla.

Ophthalmoscopic examination gave retinal and choroïdal congestion, with venous enlargement, slight optic neuritis, and choked disk.

There was constant pain, and sense of fulness in frontal region.

The only family history that could be obtained bearing upon the case was the death of one sister a year ago, from acute brain inflammation, the remainder of the immediate family being still living and in good health; and the present condition appeared to be the culmination of six years of almost constant pain and general nerve exhaustion, following the birth of the child, aggravated by the subsequent miscarriage.

At this visit no suspicion was entertained by me of any opium habit, and the case was diagnosed as passive cerebral congestion, dependent upon general neurasthenia.

The next day Dr. Wiggin called and gave me the following additional items, which at once placed the case in its proper light, and gave the key to many of the symptoms before cited. After her confinement, which was a long and painful one, she suffered severely from wandering pains in back and hips, for which her attending physician at the time ordered tincture of opium applied externally, giving at the same time ten drops by the mouth, and the ground was broken for the building of the habit. The dose steadily increased until she came under the charge of Dr. Wiggin, some six months previous to my seeing her, when she was taking four ounces of laudanum daily internally, besides continuing external applications as before. Attempts were made to stop the pernicious habit, but it was too late for wise counsel to avail, and the usual cunning of opium-eaters procured for her the drug in spite of every effort of both husband and physician.

All forms of concurrent medication had been faithfully tried, but nothing was of use except the opium, to which it became absolutely necessary to resort occasionally, as, without it, the poor lady would arouse the neighborhood with agonizing screams and cries.

At this juncture, and as a forlorn hope, it was decided to essay galvanism, hoping that its great vitalizing power might aid in restoring tone to the exhausted nerve-centres. At my suggestion Collis Browne's chlorodyne was given in place of laudanum, and produced the same effect with an ounce per diem that the four ounces of the former had done.

Central galvanism was applied with a twenty-four cell Bartlett battery, using six cells from the cilio-spinal centre to the forehead with a downward current; then from the cervical vertebrae to the solar plexus with an ascending current, each lasting six minutes, or until the skin was thoroughly reddened under the negative carbon point. For the first few days applications were made morning and night. In a week the vomiting had ceased and consciousness returned, and the evening sitting was omitted. After a month the dose of anodyne was gradually decreased, but with every diminution the nausea returned, and nothing but a return to the old dose would avail. But her condition was very much improved. She slept better, the eyes were normal as to color, and the palms were no longer dry. At the close of the second month she was able to sit up, and the dose of ano-

dyne was steadily cut down without the patient's knowledge, by adding to the chlorodyne a sufficient quantity of flavored treacle to replace each dose taken, until at that time an ounce would last three days.

Her general condition was greatly improved, and she began to take some interest in her surroundings. In two months more she commenced to go out, and came to my office for treatment when I changed the current to the Siemens and Halske cabinet cell, which, with its low tension and perfect capability of control, I regard as the ideal battery for central galvanism. There was no further trouble, and to-day, June 21st, the lady is quite well, attending to all her household duties, not having tasted opium in any form for seven weeks, and expressing unbounded delight at being free from the terrible habit which had so long been her master.

The *rationale* of the action of galvanism in this case is difficult to fully understand. When the circuit was closed over the superior cervical sympathetic ganglion, Dr. Wiggin and myself distinctly observed a sudden wavelike contraction of the distended retinal veins, which resumed their size in a few moments after the stimulus was removed. But, after some weeks' treatment, these veins became normal, and the intraocular congestion had disappeared *pari passu* with the cerebral symptoms, and having repeatedly witnessed the same phenomenon in other cases, I am led to believe that the galvanic current has a direct tonic influence upon the vaso-motor system, which accounts for the occasional surprising results obtained in cases of cerebral congestion. With the advent of increased nerve circulation came an absolute horror for the drug, and it is not easy to know to what to attribute the increase of strength of will up to the point of totally dispensing with it of her own accord, unless it be to some change in mental power, due to increased nerve tone, the direct result of what I have before termed the vitalizing power of the galvanic current. Paradism was not at any time employed.

Dr. Wiggin gives full credit to the special treatment for the cure of the case.

Reports of Hospitals.

THE PHILADELPHIA HOSPITAL.

OBSERVATIONS IN GENERAL AND CEREBRAL THERMOMETRY IN A CASE OF TUMOR OF THE BRAIN.

(Prepared for THE MEDICAL RECORD.)

By CHARLES K. MILLS, M.D.,

NEUROLOGIST TO THE PHILADELPHIA HOSPITAL.

In the *Philadelphia Medical Times* for March 29, 1879, is published an account of a case of tumor of the brain, which was presented to the Philadelphia Pathological Society. Observations in general and cerebral thermometry were made on this case, but were not included in the paper. In the present communication I will give these, with a few remarks. The following is a brief history of the case, condensed from the published account:

The patient was a white woman, aged thirty-five years, who in 1875 had secondary syphilis. During 1876 she suffered with vertigo and headache. In Jan-

uary, 1877, after an attack of terrible headache, she became paralyzed on the left side. In January, 1878, she had marked left facial paralysis, the upper as well as the lower fibres of the nerve being affected. The left arm and leg were paralyzed. She had also left internal strabismus. Farado-contractionity was retained, but lowered, on the paralyzed side. Sensibility was diminished in the left leg only. Hearing was impaired on the left side; taste was preserved; smell was defective. She was excitable and irritable. She had full control of her bowels and bladder at this time. The right half of the body gave no evidences of true paralysis, but she seemed a little deficient in strength in the right arm and leg. She improved under the use of iodide of potassium. On the 26th of August, however, she began to suffer with headache and vomiting. On the 29th she became semi-conscious, and lost control of her bowels and bladder. She perspired very freely. On several occasions, after August 30th, right unilateral sweating was observed. At this date, August 30th, her left eye began to inflame. Dr. E. O. Shakespeare, early in September, noted that she had paralysis of the orbicularis palpebrarum and external rectus, and great congestion of the bulbar and palpebral conjunctiva, with a mucoflocculent discharge. The conjunctiva and cornea were insensitive, and there was necrosis of the lower part of the latter. The right eye presented a normal appearance, its movements being unimpaired. Vision, as roughly tested, was good in this eye. She had perception of light in the left eye. The ophthalmoscope showed atrophy of the right optic nerve. The fundus of the left eye could not be seen. When she passed into the semi-conscious state, on the 29th of August, the left motor paralysis became more pronounced. Early in September she had some difficulty in swallowing; and on several occasions during the same month she had spells of slight convulsive twitching or spasm of the muscles of the mouth, and of the hands and arms. For four weeks she remained in a low, helpless condition, sometimes rallying a little. Some paralysis seemed during this time to take place on the right side of the face and body. On September 27th she showed signs of amendment, but complained greatly of pain in the left arm and leg. She continued somewhat better for four weeks, but varying considerably in her mental and physical condition from day to day. On the 30th of October she became much worse, losing power on both sides of the body, and having involuntary passages. From this time she sank, and died November 18, 1878.

On post-mortem examination, just in front of the optic chiasm the ends of two hard, pinkish-white nodules were seen, constituting what might be termed a twin-tumor. These masses were cuboidal in shape, and of about the same size, the sides of each measuring about two-thirds of an inch. They extended across the median line. They apparently more or less involved, in their growth, the basal termination of the corpus callosum, the peduncles of the corpus callosum, the lamina cineria, and anterior perforated spaces. They also probably encroached upon the roots of the olfactory nerves, the optic nerves and commissure, and the anterior portions of the circle of Willis, which seemed to have been broken in front. The base of the brain, from the posterior line of the tumor backward to the pons, was markedly softened; the softening included the visible portions of both crura cerebri, the inner portion of the floor of the right Sylvian fissure, and the inner two-thirds of the island of Reil.

A specimen from the tumor was examined by the

Committee on Morbid Growths of the Pathological Society, who reported it to be a syphilitic new-formation (gumma).

The temperatures were carefully taken, in the right and in the left axilla, from August 30th to the date of her death, November 18, 1878. They are given, for both morning and evening, in the following table:

	Morning.		Evening.	
	Right axilla.	Left axilla.	Right axilla.	Left axilla.
August 30	101.5°	101.6°	101.5°	101.6°

" 17	99	99.6	99.5	101
" 18	103	103

I will recapitulate the prominent points brought out by this table.

Observations were made on eighty-one days; eighty records were taken for each axilla in the morning, and eighty for each in the evening. The evening temperature was usually higher than that of the morning; in only twenty-one instances was the latter higher than the former. On forty-four days the morning temperature was higher in the left axilla than in the right; on nineteen it was higher in the right than in the left; on seventeen it was the same in both. On thirty-six days the evening temperature was higher in the left axilla than in the right; on twenty-two it was higher in the right than in the left; and on twenty-two it was the same in both. The following are the averages of the different observations for the entire time:

	Right Axilla.	Left Axilla.
Morning.....	99.1°	99.4°
Evening.....	100°	101.4°

During the two days of August, the whole of September and October, and the first three days of November, the temperature usually ranged between 99° and 101°, only occasionally going above or below these figures. After November 3d, until a few days before her death, it was on both sides almost constantly below the normal; toward the last it again began to show an upward tendency. On several days the fall of temperature was very remarkable; on the morning of November 9th, for instance, it was as low as 93°, and on the 16th as low as 94° in the right axilla; on a number of occasions it was 95° and 96°. On November 18th, the day of the patient's death, it shot up from 99.6° to 103°. The temperature was taken in each axilla half an hour after death, and was found to be, in the right, 107°; in the left, 106°.

I will next give the observations in cerebral thermometry. Broca, in 1877, made some investigations into head temperatures (*Progrès Medical*, 1877, and *Lancet*, October 20, 1877). In the *New York Medical Journal* for August, 1878, Dr. Landon Carter Gray published a paper on "Cerebral Thermometry," read before the American Neurological Association June 20, 1878. An abstract of this paper appeared in the *Journal of Mental and Nervous Diseases* for July, 1878, and the article in full was reprinted in the same journal for January, 1879. In the *Philadelphia Medical Times* for January 18, 1879, I published a communication read before the Pathological Society of Philadelphia, on a case of tumor of the frontal lobe of the brain. This, in addition to some axillary observations, contained investigations in cerebral thermometry. The case was, I believe, the second on record in which the thermometer had been used to locate a cerebral growth, the first being given in Dr. Gray's paper.

The stations selected for the observations were those given by Broca and Gray, as follows: Frontal stations on each side, somewhat back and above the external angular process of the frontal bone; parietal stations above each ear; occipital stations on each side of the occiput; anterior vertical stations just in front of the line of the fissure of Rolando; and posterior vertical stations just posterior to this line. The average distance of the fissure of Rolando from the junction of the nasal and frontal bones is put down by Gray as 6½ inches.

A modified Seguin thermometer was employed. The observations were made late in the afternoons of seven successive days, with the valuable assistance of Dr. Brown, resident physician at the Philadelphia

Hospital. The results expressed in the Fahrenheit scale are given in the following table:

	Right frontal station.	Left frontal station.	Right parietal station.	Left parietal station.	Right occipital station.	Left occipital station.	Right anterior vertical station.	Left anterior vertical station.	Right posterior vertical station.	Left posterior vertical station.
October 29.....	96.8	94.1	100.4	95.9	96.4	94.1	97.7	94.1	97.2	94.6
" 30.....	98.6	94.6	99	92.3	97.7	97.7	97.6	95	97.2	93.2
" 31.....	96.8	94.1	97.7	95	98.1	95	96.8	93.2	96.8	94.1
November 1.....	96.7	94.4	96.8	95	95.9	93.2	95	94	95.9	95
" 2.....	99.5	95.9	99	94.6	99.9	96.8	93.2	96.8	98.6	94.5
" 3.....	99.8	94.4	95	94.4	95.9	93.7	95.8	92.8	95.9	95.5
" 4.....	95	95.9	95.9	91.4	96.5	91.4	97.2	92.3	95	93.2
Average temperat's.	97.1	94.7	97.6	94	97	94.5	97	94	96.6	94.3

The temperature of the room during the observations ranged from 60° to 70°.

Before making any remarks upon this table, for the sake of comparisons and clearer study, I will first give some of the results obtained by Gray, and also briefly refer again to my former case.

The normal average temperatures, as determined by Gray, were as follows:

Left frontal station.....	94.36°
Right " ".....	93.71°
Left parietal " ".....	94.44°
Right " ".....	93.59°
Left occipital " ".....	92.66°
Right " ".....	91.94°
Left side of the head.....	93.83°
Right " ".....	92.92°
The whole head, exclusive of the vertex.....	93.51°
Motor region of the vertex.....	91.67°
The whole head, inclusive of the vertex.....	92.66°

In his case of tumor the temperatures at different stations were as follows:

	Left.	Right.
Frontal.....	96.75°	98.33°
Parietal.....	95°	99.75°
Occipital.....	96.75°	100.50°

The average of the left side was 96.16°; of the right, 99.52°; of the whole head, 97.84°.

On post-mortem examination, a soft, jelly-like tumor the size of a hazel-nut was found between the horizontal or posterior branch of the fissure of Sylvius and the first temporal fissure, while the whole of the right occipital lobe was converted into a colloid, extremely vascular mass, which gave way under examination; this degeneration also extending anteriorly to the tumor as far as the fissure of Sylvius. There was no apparent disease except at these points. The tumor was ascertained to be a glioma.

In my case of frontal tumor, reported in the *Medical Times*, the average temperatures of the different stations taken were as follows:

Middle frontal station.....	96.5°
" occipital ".....	95.5°
Right frontal ".....	95°
Left " ".....	94.7°
Right parietal ".....	94.7°
Left " ".....	94.4°

In Gray's case it will be seen that all the stations on the head showed a marked rise of temperature

above the normal averages. In my former case the middle frontal and occipital stations—taken in the centres of the forehead and of the occiput—and the right frontal station gave decided elevations, the other stations showing a slight increase. In the present case we have for all the right-hand stations a striking elevation, the average for these being about 97°, against a normal average of about 92.9°, a difference of 4.1°. The average of the stations on the left side of the median line was 94.3°, only about .5° above the normal. In the three cases the temperatures of the right side of the head were much higher than those of the left; while in health, it is generally admitted, and has been determined by Broca, Brown-Séquard, Gray, and myself, that the left side gives a higher temperature than the right. Between the various stations on the right side, and also between those on the left, the variations of the averages are not very marked. The average of the temperatures taken at the right parietal station was, however, from a half to one degree higher than that of any other location, and the highest single record (100.4°) was obtained here. Between the lateral and vertical temperatures the differences were not great; the lateral were, however, higher. The rise of temperature on the right side was more positive over the anterior than over the posterior half of the head.

In this case, as in the others, surface thermometry, I think, afforded some aid to regional diagnosis. It assisted at least in excluding such regions as the occipital lobe, the cerebellum, and the pons varolii as probable seats of the growth. As I have remarked in my former paper on this case, it simulated in many respects one of tumor, or other limited lesion, in the anterior part of the upper half of one lateral region of the pons. The local cerebral temperatures, however, indicated a lesion low down in the right anterior half of the cerebrum. Autopsy revealed a tumor in the anterior portion of the brain, and one visible at the base, but it was located in the median line. The probabilities are, that it chiefly exerted pressure on the ganglia and internal capsule of the right side.

The bodily temperatures taken in the axillæ, during the week that these cerebral observations were made, ranged for the right axilla from 99.5° to 102°, averaging 100.7°; for the left axilla they varied from 100° to 102°, averaging 101.2°.

Progress of Medical Science.

ON MELALEUCA PARAGUAYENSIS AND ITS THERAPEUTIC ACTION.—At a recent meeting of the *Académie de Médecine*, M. Planchon read the report of the commissioner appointed to consider a paper with the above title, which was presented by the children of Aimé Bonpland as a tribute to the memory of the companion of Humboldt. Bonpland discovered in Paraguay a plant analogous to the melaleuca of Molucca, and instituted a series of experiments with it to determine its therapeutic properties. He made a tincture from its flowers and leaves, and extracted from the plant an active principle in the form of a resin. He found that these preparations possessed a decided sudorific action. He employed them in the treatment of rheumatism, gout, syphilis, yellow fever, and cholera, and believed that his observations were sufficiently conclusive to determine that the melaleuca is a valuable therapeutic agent.—*Le Courier Médical*, April 19, 1879.

A MONUMENT TO PINEL.—The initiatory steps have been taken in Paris towards the fulfilment of the desire long felt by alienists of all countries, that some enduring memorial should be erected to commemorate the humanitarian labors of the illustrious Pinel. The *Société médico-psychologique* appointed a special committee to consider the subject, and its report suggesting the erection of a statue of Pinel at the Salpêtrière was unanimously adopted. The *Conseil général de la Seine* has voted a contribution of \$400 to the fund for the erection of the statue, and the municipal council of Paris, in which the medical element is strong, will probably do as much or more. The *Gazette des Hôpitaux* has opened a public subscription list, in which it is hoped that American names will not be entirely wanting.

CHANGES IN THE RENAL EPITHELIUM IN BRIGHT'S DISEASE.—In a paper read before the *Académie des Sciences*, M. Cornil has described a peculiar alteration of the renal epithelium, which he met with for the first time at the autopsy of an albuminuric patient last March. The patient had suffered from albuminuria not quite two months; during this period he had passed very little urine, and at times there had been almost complete anuria. He died in uræmic convulsions. Portions of the kidneys were treated with osmic acid, and when examined under the microscope, the greater part of the epithelial cells that had remained in contact with the walls of the convoluted tubules were found to present voluminous vacuoles, most of which contained a globule of albuminoid matter that had been solidified by the osmic acid. Often a cellule contained two or three of these vacuoles. The isolated cellules, with their cavities surrounded by protoplasm in which the nucleus could be seen, presented the aspect of the physalides of Virchow. The lumen of the uriniferous tubules whose cellules were affected contained large quantities of these globules, the substance of which was slightly tinged by the osmic acid, and presented a few fine proteic granules. The tubules were distended by these products. As the kidneys were greatly congested, there were also a few blood-globules in the capsules of the glomeruli and the lumina of the tubuli. M. Cornil thought there could be no doubt that these globules of albuminoid substance had been derived from the cellules, as epithelial cells with empty cavities were often met with. By combining and fusing together, the globules formed hyaline or colloid casts in the straight tubes.

In this case of Bright's disease, then, the renal epithelium elaborated in their protoplasm and discharged in the urine droplets of proteic matter, which could readily be seen by the help of osmic acid. This pathological function of the cells possesses considerable analogy with the secretion of mucus by the calciform cells of the digestive mucous membrane. In two other cases of Bright's disease, M. Cornil found in the kidneys, when treated with osmic acid, analogous lesions of the cellules, consisting in the development of small proteic masses in their protoplasm. Some of the uriniferous tubules contained also globules of albumen. The observations, however, are not yet sufficiently numerous to justify the deduction of a general conclusion. In the later stages of the disease the cells undergo fatty degeneration, but contain the proteic globules until they are disintegrated. M. Cornil found the same lesion of the cellules in a case of cystic kidney. The patient had died in uræmic coma. In this case the cysts were formed at the expense of the urinary tubules. In the dilated tubes that were in

process of cystic transformation, the cells lining the walls presented in their interior vacuoles and globules of albumen. The cavity of the tubes was filled with globules that had escaped from the cells. M. Cornil states that the lesion can be recognized in fragments of the kidney treated with Mueller's fluid, but that it is rendered much more distinct by the use of osmic acid.—*Gazette Médicale de Paris*, May 3d.

EXPERIMENTAL INVESTIGATIONS ON THE ACTION OF INHALED SUBSTANCES.—M. Schottelius reports the results of two series of experiments on dogs, which were undertaken with a view to determine the action of inhaled dust on the lungs. In the first series a single insufflation through a tracheotomy canula was practised, the substances employed being, in one set of cases, inorganic dry bodies, viz., vermilion, Berlin-blue, and magnesia usta, and in another set, dried and powdered organic substances, such as feces, pus, etc.; in the second series the animals were compelled to inhale various substances for a prolonged period. The experiments with vermilion and Berlin-blue produced lesions resembling in many respects those of anthracosis pulmonum. The colored particles were found in the epithelium of the alveoli, in the lymph-canals and lymphatic glands, and later in the stellate connective-tissue cells. Here and there also, the pigment granules were found in the epithelium of the bronchi, and in the lymph-passages situated in the deeper layers of the bronchial mucous membrane. Dr. Schottelius could not demonstrate the existence of stomata leading directly from the lymph canals into the alveoli. These inorganic substances never excited any severe or destructive inflammation. On the other hand, the insufflation of the different organic substances, which, it must be noted, were all either already involved in, or ready to enter upon the process of decomposition, produced broncho-pneumonia with special tendency to ulceration.

In the second series of experiments the dogs were confined in large, well-ventilated boxes, and were made to inhale at regular intervals finely divided organic particles. One dog inhaled for an hour a day during eight weeks, the dissolved and atomized sputa of tubercular patients; another inhaled during the same period the sputa of non-tubercular patients; a third inhaled Limburger cheese rubbed up in water, and a fourth the brains of different animals. All the dogs when killed presented the same lesions: tubercle-like nodules in the lungs and pleura, which Dr. Schottelius divided anatomically into three groups. The nodules of the first group proved to be miliary hepatizations. Those of the second group were formed by accumulations of cells in the adventitia of large and small bronchi and of the blood-vessels, and resembled closely the inflammatory foci developed after insufflation of inorganic substances. The third group comprised nodules formed by the closure of small bronchi.

Dr. Schottelius claims that the similarity of the lesions in these cases proves that tubercular sputa is not the only substance which when inhaled will produce tuberculosis, and hence that it is not a specific infectious agent.—*Allg. med. Cent. Zeit.*, No. 33, 1879.

SCHOOL VENTILATION.—The subject of the better ventilation of schools is at length being agitated in London. There seems to be there, as with us, room for great improvement in this direction.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 9, 1879.

MEDICAL INSPECTION FOR SICK CHILDREN.

THE Medical Corps, appointed by the Board of Health to visit tenement-houses, inquire for, and give general directions—if need be, prescriptions—for the relief of sick children, is thus far doing its work satisfactorily and with good results.

The rate of mortality during the heated season, since the employment of such a corps of medical visitors, has not increased, notwithstanding the yearly increase of our population.

In the year 1877—that following the inauguration of the plan—the highest mortality for a single week in the months of July and August was 825; the next highest was 756.

In the year 1878 the highest mortality for any single week during a corresponding period was 820. The present outlook is, that the mortality for the months of July and August of this year will not exceed what it was for the years 1877 and 1878.

To show that notable benefit has followed the present plan of inspection, we give the mortality reached in corresponding weeks within the same months—July and August—for the years 1875–74–73–71–70 and 68. In 1875 the highest mortality was 934 and 939; in 1874, 824 and 861; in 1873 it was over 900 twice, and over 800 once; in 1871 it reached 820 but once; in 1870 there was one week in which it reached 980; and in 1868 the highest mortality reached in any single week during the same months was 1,142. All these were years in which the heated season was of average severity, and the inhabitants had an ordinary immunity from summer diseases. Besides, so far back as 1870, the population was nearly 100,000 less than at the present time. No increase in the rate of mortality for the year 1878 as compared with the year 1877, with a steady increase of population, is good evidence of itself that the work instituted

by the Board of Health has not been barren of good results; but when the comparison is made with the rate of mortality for the years from 1868 to 1875 inclusive, this becomes much more apparent.

The figures we have given include the number of deaths from all causes; but, when the investigation was restricted to diarrhoeal troubles among children, about the same proportion was found to exist. The work, then, which this medical corps is doing under the immediate supervision of the Board of Health, is of vital importance to the city, and should be well sustained.

THE RATE OF MORTALITY IN THE CITY OF NEW YORK.

It will not be out of place in this connection to lay before our readers some of the influences which have a special tendency to increase the death-rate in the city of New York.

The statement has been made that in other cities—for example, in Brooklyn and in Philadelphia—the rate of mortality is far less than in New York; hence, the former, so far as human existence is concerned, are much more desirable localities in which to live.

Externally it may appear so, but the inner aspect of the subject, we think, proves that the city of New York is not altogether a whited sepulchre full of dead men's bones.

The rate of mortality in all the three cities mentioned has had for its basis the estimated population, and, of course, it is easy to understand that when estimation becomes over-estimation, the rate of mortality will correspondingly decrease.

When we look at the estimated increase in the population of the city of New York for nearly five years, it is found to be 6,000; while for the city of Brooklyn it reaches 86,000; and Philadelphia has reckoned her increase during the past three years as 84,000. These, however, are mere estimates; yet they are such as give for Philadelphia the lowest rate of mortality. But it must not be forgotten that the three years for that city embrace the Centennial, in which a large representation of the population of the world took up their abode within her borders.

Within the last five years there have developed within the city of New York certain improvements which render it very probable that its present population has been under- rather than over-estimated. For instance, our system of flats has made it possible for many, who previously were unable to be residents of the city, to now make their homes within its limits. Again, our elevated railways have undoubtedly kept among us as residents many who formerly visited us only for social entertainment or for business purposes. In the first place, then, the estimated population of a city may materially change the rate of mortality among its inhabitants.

In the second place, the rate of mortality for the city of New York is affected from a source which is

felt in Brooklyn and Philadelphia only to a very limited extent—namely, deaths among foundlings. This city has a foundling asylum, and to it are taken not only the city's own foundlings, but foundlings from Brooklyn, from Philadelphia, and from all parts of the United States, and that for the reason that no special provisions have been made in other places for this class of unfortunates. Every year about 600 foundlings die in the city of New York, and thus become a special source from which the rate of mortality for the city is increased.

In the third place, in estimating the rate of mortality, we must take into consideration the number of deaths which occur in county institutions. Between five and six hundred deaths occur annually in the public institutions belonging to Kings County, but they are situated outside of the limits of the city of Brooklyn. These institutions in the county of New York add their mortality to that which obtains in the city proper, and therefore exert a special influence upon the death-rate not felt by many other large cities in our country. More foundlings die in New York annually than in all the county institutions for the county of Kings, and the one increases the rate of mortality for the city of New York, while the other leaves the rate of mortality for the city of Brooklyn unaffected.

In all the public charitable institutions for the city and county of New York the mortality for the years 1876, 1875 and 1874 was in round numbers one-sixth of the total mortality for the entire city and county, which are one and the same with reference to mortuary statistics.

In the fourth place, death among emigrants is a special source from which the mortality of the city is increased. Sick emigrants are taken to Ward's Island, where about 100 die annually and are added to the city's mortality.

Again, New York is a rendezvous for certain classes which derive their support largely from the country and from other cities, and their habits and mode of living give rise to an abnormal degree of mortality.

Besides, New York has been regarded by some institutions within the borders of neighboring States as a sort of general receptacle for all that is diseased and likely to die early, after being shipped hither, and the alertness of the managers of some of our own institutions has been called into requisition to prevent themselves from being made the subjects of imposition.

From what has been said and the figures given, we think it will not be difficult to see that New York is subject to special influences which tend to increase its rate of mortality, but which do not, at least to nearly such an extent, affect the rate of mortality in other cities.

The simple fact that the rate of mortality in the city of New York is higher than that in other cities is not positive evidence that other cities are healthier than is New York.

TRICHINOUS PORK.

THE recent fatal cases of trichinosis in the city of Brooklyn, and the threatened action on the part of the British authorities to make stringent regulations in regard to the importation of American pork, naturally direct attention to this subject. From such facts and statistics as are at command to this date, the question stands as follows:

Professor Richard Heschel, of Vienna, recently said, that an examination of American hams had been made in North Germany to test how far they were infected with trichinæ. No particulars are given regarding the manner in which the search was made, but the results published state that one in from five to ten hams contained trichinæ, whereas the average in Westphalian hams was one in 2,000 to 2,500.

More recently two physicians at Chicago, Ill., Drs. H. F. Atwood and W. F. Belfield, made an examination for trichinæ among 100 hogs, and of these eight contained the parasite; some were badly infected, while others contained but few. This result, showing that twelve per cent. of hogs are infected with trichinæ, is an alarming average, for it indicates that every twelfth time pork is eaten probably the consumer partakes of trichinous meat. An examination, however, made in Chicago in 1866, showed that about two in 100 hogs were trichinous.

We are not at present prepared to accept such sweeping conclusions as the first two, for the following reasons. In the first place, no systematic investigation in regard to trichinæ in hogs has been made by competent men. Before this has been done, we do not wish to draw general conclusions derogatory to the porcine family throughout the United States.

Admitting the correctness of the Chicago examination, we decline to allow a single local investigation to be accepted as a standard. The very nature of this parasitic disease suggests that its existence is probably local and confined to certain districts. German hogs are troubled but little with trichinæ, and in England pigs are said to be free from this parasite; but probably careful examination would show its existence. It was in England that the *Trichina spiralis* was first discovered in 1833.

It is highly probable that, in some parts of the United States, trichinæ in hogs exist to a greater extent than in other localities, and it is, therefore, not just to select a single consignment, which probably came from one district, and from its examination deduce general statements.

Professor Heschel made all his observations upon American hams, and states that from 10 to 20 per cent. were infected with trichinæ. Drs. Atwood and Belfield, in the one hundred hogs examined in Chicago, did not find a single trichina in the hams, but met them in other parts of the bodies, particularly the "psoas muscle." On the other hand, in the two fatal

cases occurring in Brooklyn, the disease was contracted by eating uncooked American hams. Here are discrepancies showing that the microscopical examinations so far made are not satisfactory, and it may be suggested that those interested in the sale of pork, ham and bacon have systematic examinations made of the meat passing through their hands. This would probably lead to valuable results, and perhaps show that trichinæ in pork, hams, etc., do not exist to the extent the statistics we have given indicate. On the other hand, the parasitic disease might, in that way and to some extent, be localized.

As trichinous meat is rendered practically harmless by thorough cooking, we cannot condemn too strongly the practice, still prevalent among certain classes, of eating raw ham. The trichina is so little known in Europe, that it is possible only few who come from there here, and thus eat raw meat, are aware of the risk they run in continuing the practice.

The fact that this parasite is now constantly met with in the dissecting-room appears to indicate that the number of those who are involuntarily acting the part of its host is largely on the increase, while few are aware of the acquisition they have made. Fatal cases are so rare that they may be probably attributed to eating such samples of trichinous meat as are referred to by Leuckart, who counted 160,000 trichinæ in a single ounce. If we suppose a ham to be thus infected and six ounces to be eaten, nearly a million trichinæ would pass to the intestines; within forty-eight hours these would be sexually matured, and in six days afterward a countless brood of larval trichinæ would be set free. These, all boring and perforating the intestines in their attempt to migrate, would naturally give rise to serious, if not fatal results. Such cases are no doubt rare. More often the number of trichinæ is small, producing a larval brood that passes through the system without serious injury, and, becoming encysted, remain harmless.

In conclusion we repeat our suggestion that a more general and systematic examination of pork should be made at packing-houses, by those acquainted with and able to detect the parasite, and that the public, on their part, should avail themselves of the simple but effectual protection obtained by thoroughly cooking all preparations of pork when served for the table. The Board of Health of this city has applied several times for money with which to employ meat inspectors, but have, thus far, failed to obtain the requisite appropriation.

THE Royal College of Physicians of London have conferred the Baly Medal for Physiology upon Charles Darwin.

REFERRING to the not unfrequent habit of giving to deceased parties titles to which they have no claim, the *Medical Press and Circular* quotes the lines of Pope put into the mouth of a dying lady of fashion:

"Narcissus! give this cheek a little red,
One would not be quite hideous when one's dead."

Reports of Societies.

WEST CHICAGO MEDICAL SOCIETY.

Regular Meeting.

DR. NORMAN BRIDGE, PRESIDENT, IN THE CHAIR.

THE PRESIDENT exhibited a new obstetric forceps, the invention of DR. JOHN BARTLETT. It was for use in high positions of the head, and to make traction in the direction of the axis of the superior strait. Dr. Bartlett claimed that it would accomplish direct traction in a much simpler way than the forceps of Tarnier. It resembled somewhat the forceps of Dr. Hobbs. In construction, the striking peculiarities were a long straight shank, with its two parts placed one in front of the other, instead of side by side; the shank leaving the blades at a more acute angle than was the case with most forceps heretofore in use; the handles being parallel to the axis of the blades, and long and strong. It was, in the view of the inventor, a fact of some moment that as the axes of the handles and blades were parallel, the obstetrician could always know the exact direction in which he was making traction by noting the direction of the handles. By this instrument direct traction could be made without forcing backward the perineum.

DR. H. M. LYMAN did not regard the instrument as a valuable addition to the armamentarium of the obstetrician. It was too awkward, and the handles were placed so far in front of the blades (above them), that although parallel to their axis, it must be difficult in using them to know just where the blades were, and what they were doing.

DR. BOTTSFORD thought the instrument might be a useful one, but that it would profit by the addition of the saw handle of Dr. Hobbs's forceps.

FRACTURE OF THE NECK OF THE FEMUR—ABILITY TO WALK.

DR. E. W. LEE detailed the history of a case of fracture of the neck of the femur, the patient being able to walk about after the injury. The patient was a boy of eleven years, who caught cold skating on Christmas day, walked home, and was sick next day, and in two or three days was obliged to go to bed. There was fever, painful joints, the knees and left hip particularly being involved, and the attendant supposed him to have acute rheumatism. The case failing to improve, Dr. Lee was called January 23d, and found pulse 140, hot moist skin; there had been profuse night sweats; the hip was swollen, and great pain was caused by the slightest motion. The knee was raised on a pillow; it was painful, but not swollen or tender. To appearances, there was inflammation of the hip-joint. Cinchonidia, morphia, to quiet pain, and hot fomentations locally were ordered. In a few days the boy could sit up in a chair. The hip was still painful and swollen. Dr. Lee then determined to examine the case more fully. On the patient assuming the recumbent posture with both legs straight, he was surprised to notice that the limb of the painful side was one and a half inches shorter than its fellow. He then anesthetized the patient, and made, with Dr. Parkes assisting, a thorough examination of the joint, with the result of finding an unmistakable fracture of the neck of the femur. It was ascertained afterward that on Christmas day the boy had fallen upon the ice a distance of six or eight feet—a fact he had denied; that he had walked

home, a distance of several blocks; that he had been about the house, gone on errands to the market, and played upon the door step the second and third days after the injury, and before he had been obliged to take to his bed. There had been no sudden giving away of the hip-joint, but he had got gradually worse, till he was obliged to keep the recumbent posture. Great pains had been taken to ascertain accurately the history, and Dr. Lee felt sure the facts were as he had stated them. That the boy had walked about after the injury as stated, was vouched for by numerous reliable witnesses.

He thought it not unlikely the case had been complicated early by acute rheumatism, but the theory of the trouble of the hip was that an impacted fracture had been sustained which had not become disengaged during the time the patient was walking about.

On making extension of the limb, the appearance of swelling about the hip had almost wholly disappeared, showing that it must have been due to the thickening of the muscles incident to their contraction.

SPLINT FOR FRACTURED THIGH.

Dr. Lee next exhibited a splint, of his own device, for treating fracture of the thigh. It consisted of a firm continuity of wood posteriorly, the entire length of the limb—and more, a fixed foot-piece, projecting from the lower extremity, and above this a movable foot-piece taking its motion and attachment from the first by means of an adjustable screw; numerous parallel strips of thin splint material, an inch wide, fastened to canvas and attached to the upper end of the splint in such a way as to easily surround the thigh, inclosing it firmly. This part of the apparatus was about a foot long, and fitted the thigh accurately. Counter-extension was secured by pressure upon the conical form of the thigh by this wood socket—simple tapes being used to tie it firmly about the limb. Extension was made by adhesive straps attached to the thigh below the seat of fracture and fastened to the movable foot-piece, the force being adjusted by the screw connecting the two foot-pieces. The splint was to be properly padded with cotton. No pressure against the perineum was required. The apparatus was very convenient, as the patient could be easily moved about without danger of displacing the fragments. It was a labor-saving machine for the surgeon; he knew of no splint that gave such good results with so little trouble to the surgeon. He averred that he had treated with it several cases, in both children and adults, in which recovery took place without a particle of shortening.

Dr. TAGERT referred, in the discussion, to a case he had treated of a man of fifty, who had fallen from a street-car, and fractured the neck of the femur. He walked ten blocks after the injury, and no shortening occurred till two weeks afterward, when it suddenly appeared and reached the degree of two inches.

ULCERATION OF THE FACE IN A CASE OF SCARLATINA.

Dr. BRIDGE reported a case of extensive ulceration of the face in a case of scarlatina. The patient was two years and four months old. He first saw the case during desquamation, and two weeks from the beginning of the sickness. The case appeared to have been a severe one; the throat was considerably swollen, but contained no ulceration, nor was there any tendency to the formation of abscess at the angle of the jaw. An ichorous fluid was flowing from the nose, and this, with the odor, suggested a diphtheritic

complication. The face was involved in erysipelas, which did not extend to the sides of the neck. Both eyes were closed by the swelling, the left most firmly. On the external surface of the left under eyelid was an ulcer, measuring one-half by three-quarters of an inch, quite deep, but not involving the border of the lid. The eye was not inflamed or injured. The erysipelas soon disappeared from the face, and the general condition improved for a time, but the ulceration continued, and the child died two weeks later of exhaustion. At death the ulcer had become a deep slough, measuring laterally two and a half inches, and two inches vertically, but it had not invaded the border of the eyelid; it had destroyed the integument of a considerable portion of side of the nose and cheek.

The Society then adjourned.

CHICAGO GYNÆCOLOGICAL SOCIETY.

Regular Meeting.

Dr. H. P. MERRIMAN, IN THE CHAIR.

THE MANAGEMENT OF THE THIRD STAGE OF LABOR.

Dr. DE LASKIE MULLER read a paper on this subject. He thought too little attention was usually paid to this, what he believed to be the most important stage of labor. Practitioners were too much in a hurry to cause the completion of the process of expulsion of the placenta. Time was important—time between the uterine contractions which detach the placenta from the walls of the womb—to enable small coagula to form and plug up the orifices of the uterine sinuses. It was improper to hasten the expulsion of the placenta by kneading the uterus into immediate contraction. When the uterus is slow to contract and expel the placenta time should be allowed, provided no serious hemorrhage occurred; the detachment from the uterine walls should be accomplished by the unaided efforts of the organ itself.

Too sudden and forcible delivery of the placenta exposed a patient to danger of post-partum hemorrhage, and to retention of blood in an imperfectly contracted uterus, which might decompose and cause both severe after-pains and septicæmia. He queried whether this was not a cause of the so-called "milk-fever." He thought subinvolution of the uterus might result from the bad practice referred to. The chief obstetric value of ergot was in the third stage of labor; he thought it should rarely if ever be used in the second stage.

The placenta should be delivered from the uterus after its detachment by bringing down its border with the finger, never by traction upon the cord. When inertia of the uterus occurred without hemorrhage, give time and restoratives; if serious hemorrhage occurred, introduce the hand and deliver the placenta and secure contraction. Irregular contraction, as that of the hour-glass variety, might best be overcome by moderate force applied continuously, and if the placenta was adherent it should be separated by the hand and delivered as soon as diagnosed.

Dr. RALER objected to the practice of using disinfecting injections during the first twelve hours after confinement. Fresh wounds would absorb septic matter, but in a few hours a glazing of the wound surfaces appeared which protected them from absorption. Injections would wash away this glazing material and thus make absorption more likely to occur.

Dr. DUDLEY believed in using hot-water injections

into the uterus in every case. It was very useful in case of hemorrhage and removed clots. He referred with favor to the use of hot injections of carbolized water every four hours to protect the parturient canal from absorption of poisonous matter.

Dr. T. D. FITCH thought milk-fever resulted from mammary congestion; that after confinement a free evacuation of the bowels should be early secured; that in the third stage of labor it was proper to press upon the uterus, rather upward than downward, and to make traction upon the cord.

DRS. NELSON and JONES always watched closely the womb for at least an hour after labor, to make sure of firm contraction.

The Society then adjourned.

CHICAGO MEDICAL SOCIETY.

Regular Meeting.

DR. E. INGALS, PRESIDENT, IN THE CHAIR.

TUMORS OF THE LARYNX.

DR. D. W. GRAHAM reported a case of tumor in the larynx in a girl eight years old. He had treated the child some months previously; had lost sight of her, and knew nothing further of the case till called to make a *post-mortem* examination. He had first seen her two years previously, and had last treated her in the November preceding. There was no evidence of a hereditary taint except as shown by the appearance of venereal warts on the person of a younger brother, whom Dr. G. had treated. Aphonia appeared when the child was three years old, and had persisted to some degree until her death. There were no other symptoms; the general health appeared good. Iodide of potassium was given to some extent, but with no particular effect. The history given of the closing days of the case by the friends was, that about a week before death dyspnea came on for the first time. It did not exist to an alarming degree, and nothing seems to have been done for it. Half an hour before death a fit of severe dyspnea came on, which persisted until from its effect life was extinct.

Large papillomatous growths were found above and below the vocal cords, covering a large part of the surface of the mucous membrane of the larynx and obstructing considerably the glottis.

There was found just below the cords a mass of quite tenacious mucus, of a size sufficient, in the event of its engaging in the glottis, to seriously obstruct respiration. Dr. G. believed this mass of mucus to have been the cause of the final fit of dyspnea; that it was thrown by a coughing effort against the vocal cords and abbreviated greatly the breathing space, and thereby induced the strangling.

TUMORS OF THE VOCAL CORDS.

DR. E. F. INGALS read a report of two cases of tumor of the vocal cords which he had removed by operation.

CASE I. was of a seamstress, twenty-three years old, who complained of hoarseness and some pain at times in swallowing. The larynx—including the vocal cords—was congested; and a small tumor, slightly pedunculated, was found attached to the under surface of the left cord, near its anterior extremity. Astringent powders were applied, and soon the congestion disappeared and the tumor grew less. The larynx was very intolerant of instruments.

Repeated attempts were made to seize the tumor

with McKenzie's tube-forceps, with blades opening antero-posteriorly, but it was not possible to pass the blades between the cords and reach the tumor, so near was the latter to the anterior commissure. Then that part of the tumor which reached above the cords was grasped by the same instrument, the blades being turned so that they opened laterally; it was crushed, and a part of its covering was brought away. In three days there was nothing apparent at the site of the tumor but a slight prominence. In ten days the cord was normal, as was likewise the voice.

CASE II. was a fibro-cellular tumor on the right vocal cord of a woman of twenty. She had had hoarseness for over a year, it having commenced in a cold. There was occasional dull pain in the larynx. The patient had received a great deal of treatment for laryngitis. A small tumor was found growing from the under surface of the right cord, near its anterior extremity. It measured at its base "about six millimetres," and at its apex half as much.

During ordinary respiration the epiglottis hung so far backward that only a part of the glottis could be seen by the laryngoscope. On uttering a high-pitched "a" tone the tumor projected above the cord. In this case it was impossible to grasp the tumor with the forceps opening antero-posteriorly. Accordingly it was grasped during phonation with the blades opening laterally, and most of it was torn off. It was soft—indeed, semi-fluid. Five days later only a swollen spot on the cord told of the location of the growth, and a week later this was gone. The voice was then normal.

NEW INHALING APPARATUS.

DR. F. H. DAVIS made some remarks on the local treatment of bronchial and pulmonary diseases, and exhibited to the Society a simple and cheaply made inhaler which he had designed. It consisted of a tin vessel of the shape and size of a small dinner-pail, into which another and smaller vessel, bottom side up, fitted, the bottom of the latter having a broad flange, so that it acted as a cover for the larger one. This flange was perforated. A short tube of tin an inch in diameter projected from the centre of the cover, to which was connected a rubber tube nearly or quite an inch in diameter, through which the patient inhaled. By a set of sensitive and free rubber valves in the tin tube the patient was enabled to inhale from the inhaler and exhale into the atmosphere without letting go the rubber tube. Into the inhaler it was Dr. D.'s habit to put half a pint of boiling water, to which was added the medicament. Inhaling through the tube the air was compelled to pass down through the perforations and up through the fluid.

He was satisfied that in most inhalers the tubes were too small in diameter; they obstructed respiration, which was a disadvantage.

UNUSUALLY LATE CHLOROFORM ASPHYXIA.

DR. F. C. HOTZ reported a case under the above title. It was rare for any serious accident from chloroform anesthesia to occur except during or immediately following its administration. According to Turnbull, in only 10 deaths out of 160 from chloroform did death occur *after* the anesthesia. The case he was to report was one where a small dose of chloroform was given for a short operation.

T. J., *æt.* 8, was perfectly healthy. He was brought for an operation for convergent strabismus. Having eaten nothing since morning, he was, at 3 P.M., chloroformed, an Allis's inhaler being used. In five minutes he was anesthetized, and the operation was

proceeded with, the inhaler being withdrawn. One eye was operated upon, and Dr. H. had commenced that upon the other, when the boy suddenly began to hiccough and become dusky in the face, and the pupils became widely dilated and fixed. The tongue was drawn forward, the foot of the table was elevated, and artificial respiration, "by rhythmic compression of chest and abdomen," was practised. The hiccough soon stopped, the lividity grew less, and the pupils became movable, and the table was then brought to the level. The hiccoughing immediately returned. The table-foot was again elevated, and the operation, in this position, was finished. In ten minutes the boy became conscious. No nausea occurred.

It was found that only about 30 minims of chloroform had been used, and, by chemical tests, that the article was pure.

In an experience of fifteen years this was the first instance of a short and regular narcosis assuming a serious aspect at a time when the anæsthetic had been discontinued for a number of minutes, and when the patient is usually regarded as out of danger.

THE CHIROPODISTS.

DR. EDMUND ANDREWS read a paper on the above subject.

From a condition of the most ignorant of itinerant quacks, and the most disreputable in their deception practised upon the people, the corn-doctors had, many of them, settled down to permanent residence in communities, and seemed to be trying to develop a creditable specialty. He thought they might attain, by more science and wider knowledge, a position like that of the dentists, with a specialty as legitimate and well-defined.

There were hardly any books or other literature on the subject of their art in the hands of the chiropodists; they were obliged to learn of each other, and not from books. There was quite a literature touching on corns and bunions, and other disorders of the feet, scattered through our medical and surgical writings; but it was very difficult to gather it up, and, it should be confessed, it was of a disgracefully poor quality. Surgeons of world-wide fame had, when touching upon this subject, displayed gross ignorance of pathology. He thought it would be proper for the chiropodists to extend their practice to such disorders as talipes; but as yet they were wholly incompetent to treat such cases. Corns furnished nineteenth-twentieths of their business. Our own books were contradictory as to the definition of a corn. Two growths were confounded under this name. One was a chronic inflammation of the skin, with thickening of the cuticle, and should be called simply a callosity. The true corn resembled a wart on the hand. "The irritated derma sends upward from one to several elongated vascular papillæ, exactly like the minute finger-like papillæ constituting the framework of a wart." There was thrown out about these papillæ "a nodule of hard cuticle, whose circumference merged into the callosity of the adjacent inflamed skin. The pressure of the faulty boot sank the whole mass into the skin and subjacent tissue, so that the bed of the corn was concave. The small mass of horny cuticle surrounding the little column of papillæ was crowded, like a conical nail, into the flesh, while the adjacent callosity spread out like the head of the same. Hence, if a corn was taken out at this stage, there remained a conical-pointed cavity, "and in the central spike may be found papillæ and blood-vessels." Pressure might destroy the papillæ; and

"sometimes the apex of the funnel was occupied by a little cavity containing serum and pus." The art of the chiropodists consisted chiefly in paring the callosities and digging out the central spike, and then obviating further pressure. Their instruments were peculiar. Some had small, chisel-shaped knives, the edges running obliquely across the instrument, and the paring was done by a lateral movement. Some chisels had semi-circular edges. Some operators used narrow and blunt scalpels. "After the corn was removed, a piece of thick, soft buckskin, with a hole in it, is applied around the cavity, and retained by means of diachylon or adhesive plaster. The corns would return in one to six months.

One chiropodist had invented a new operation for ingrowing nails. With the view that the difficulty was overgrowing flesh, and not ingrowing nail, nothing was done to the nail itself; but, at a little distance from the border of the latter, a lanceolate piece of flesh was removed, and the edges of the wound brought together with sutures. The healing in that position drew the overspreading flesh from the border of the nail, and the cure was complete. He thought that operation was one with many sensible features.

The Society then adjourned.

Correspondence.

NOTE ON THE CAUSE OF SUDDEN DEATH DURING THE OPERATION OF THORACENTESIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—At a recent meeting of the Pathological Society, Dr. Beverley Robinson, in some remarks upon sudden pulmonary œdema, suggested that it was an accident which might occur during the operation of thoracentesis, and determine a fatal issue to this operation.* It seems to me unnecessary to suggest possible causes for sudden death under these circumstances, when the cause is so obvious. It is established that, in normal conditions, the expansion of the thorax during inspiration necessarily determines traction outward on all the contents of the thoracic cavity; on the heart, therefore, as well as on the lungs, and in the same direction. This direction coincides with that assumed by the walls of the heart during cardiac diastole, and is directly opposed to that of the same walls in systole. The effective force of each ventricular systole is, therefore, diminished by the oppositely directed force of inspiration. Or, in other words, the force with which the blood is thrown into the aorta and the coronary arteries is a resultant of two forces acting in contrary directions; on the one hand, the force of inspiration tending to draw outward the mobile walls of the cardiac cavities, and the blood contained in the latter; and, on the other hand, the force of the ventricular systole compressing the walls inward, and by thus displacing the contents of the ventricles driving these contents forward.

It may be noted in passing, that, owing to this circumstance, a real intermittence of vascular shock is secured to the brain, since the periodical diminution in the force with which blood is thrown into the cranial cavity coincides with the periodical aspiration of blood from that cavity during inspiration. Such

* See minutes of meeting of May 14th.

intermittence would not exist were it true, as has sometimes been erroneously asserted, that the force of the cardiac systole is stronger during inspiration than expiration, for then the effect of inspiration upon an intracranial pressure would be compensated.

The "negative pressure" ("negativen Druck"), which should thus normally be exercised on the heart, is diminished whenever the expansion of the thorax is lessened, as by pleuritic effusions. The heart, therefore, becomes accustomed to act independently of such pressure, which is equivalent to saying that motor force is not stored up in its ganglia in sufficient quantities to overcome the habitual amount of physiological hinderance which has been removed. When, therefore, this is suddenly restored—that is, when the operation has freed the thorax from the effusion which may have held one of its sides motionless, and the chest-walls begin to expand, they draw not only on the compressed lung, but on the heart, tending by "negative pressure" to arrest its action in diastole. This tendency is not resisted as effectively as in physiological conditions, because by morbid habit the physiological reserve of force in the excito-motor ganglia has been reduced. If the reduction has fallen below a certain minimum, or if the cardiac muscle is degenerated, or if the expansion of the liberated chest walls be sudden, syncope, or diastolic arrest of the heart, is almost inevitable. It is again only a question of degree whether such arrest shall prove permanent, *i. e.*, fatal.*

[*Note.*—Lambert, in a thesis on the method of Waldenburg (Paris, 1877, p. 28), calculates that the negative pressure exercised by pulmonary elasticity varies from 9 to 40 mm. of mercury. This negative pressure adds itself to the positive pressure exercised by the blood—pressure equal to one atmosphere, *i. e.*, 760 mm., and the sum of the forces which dilate the heart and facilitate diastole are thus equal to 809 mm. of mercury. The forces which tend to facilitate systole are represented by the pressure of the intra-pulmonary air, which is 703 mm. in deep inspiration, 759 mm. in calm inspiration, 762 in calm expiration, and 847 in forced expiration. "If we suppose that the glottis were closed during inspiration, then the volume of the cavity would increase without any atmospheric air coming to fill the vacuum produced. It is evident that then all the dilatable organs contained in the cavity would increase in size, and the force of suction exerted on the walls of the heart would be at its maximum. . . . In man, even when the glottis is open, the ærian canal is too narrow to permit the vacuum to be immediately filled; hence *partial* dilatation of vascular cavities during inspiration. During expiration, on the contrary, air does not pass out rapidly enough; it is partly compressed, and the pressure is transmitted to the external walls of the heart. It is this simple fact which determines the influence exercised on the circulation by the respiratory movements."]

M. PUTNAM-JACOBI, M.D.

DR. J. MILNER FOTHERGILL has written a letter to the *New York Herald*, appealing to American exporters to send cream to London; he thinks it might be a practicable and profitable venture, and it would furnish a much needed article to the inhabitants of London.

PROVIDENT DISPENSARIES.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In the recent discussions upon Dr. Sturges's paper, in the County Medical Society, the various speakers alluded to what is known as the Provident Dispensary System only to condemn it, while from their remarks it was evident that they were ignorant of its claims, of its growth abroad, and of its undoubted success wherever fairly tried.

The system is briefly this: A number of families living near each other, whose income does not exceed a certain sum, combine to form a society or union for the purpose of obtaining medical relief.

The machinery is very simple. A fixed sum, varying in amount according to the number in the family and the ages of the children, is paid weekly in advance into a common fund. This payment entitles the family to send, in case of illness, for any one of a certain number of physicians, the particular family adviser being previously selected if desired. In most unions, confinements and surgical cases are excluded, or treated at special rates.

At the end of a definite period, usually a year, the books are balanced and the physicians are paid according to the amount of the work done, expenses having been deducted.

The limit of income, beyond which one is not entitled to membership, varies in different unions. The average is about \$500.00 per annum.

This description applies to the Provident Dispensary System of England, which has grown to immense proportions within the past ten years.

It is not a measure for the relief of sick paupers; for them the hospital and dispensary clinics must still open their doors.

It is especially for that class who can, and who ought to pay for their medical treatment, and, I might add, who are willing in most cases to pay when the subject is presented to them fairly, before they have become debauched and medically pauperized by contact with our present disgraceful system of medical charity.

This subject is receiving abroad the attention which its importance demands.

In March, 1870, a meeting was held in London, which was presided over by the late Sir William Fergusson, at which 156 members of the medical profession were present. The following resolutions were passed:

"That this meeting is of opinion that there exists a great and increasing abuse of out-door relief at the various hospitals and dispensaries of the metropolis, which urgently requires a remedy; and

"That it is the opinion of this meeting, the evils inseparable from the system of gratuitous medical relief administered at the out-door department of hospitals and in free dispensaries can be in great measure met by the establishment, on a large scale, of provident dispensaries, not only in the metropolis, but throughout the kingdom, and by improved administration of poor law medical relief."

A large committee was then appointed, which apportioned the subject among four sub-committees: Dr. Meadows, Dr. J. E. Pollock, Dr. A. P. Stewart, and Mr. Spencer Wells, chairmen. Dr. Meadows stated at this meeting that "the probable income of half the out-patients of the London hospitals may be estimated at from £1 to £1 10s. (\$5.00 to \$7.50) a week, and of one-fourth at more than this." I think this would be equally true of New York City.

* See case in *Am. Journ. Med. Sciences* for April, 1879, of Transient Syncope during Evacuation of Pleura by Capillary Trocar. The patient ultimately recovered.

The various sub-committees appointed, as above stated, patiently and thoroughly investigated the subject. They "found that it was hopeless to endeavor to make people provident while they were educated to dependent mendicant habits at free dispensaries and out-patient departments of hospitals."

In April, 1875, a memorial was addressed to the President and Committee of the British Medical Association by 303 members of the profession, including Sir William Fergusson, Sir William Jenner, Sir William Gull, Sir Rutherford Alcock, Mr. Prescott Hewett and Mr. Erichsen, representing "that the manner in which the hospitals and free dispensaries, with some few exceptions, throughout the kingdom are at present conducted, inflicts a serious injury upon many of the most deserving members of our profession; and while the indiscriminate or almost indiscriminate bestowal of gratuitous medical relief upon all applicants lowers the whole scale of our professional remuneration, it is far from being a real boon to the working classes themselves, and cannot fail in the long run to have a prejudicial effect upon the nation at large."

The leading members of the medical profession one by one gave their final adhesion to the movement, and in April, 1877, a second general conference was held, presided over by Dr. Acland, Regius Professor of Medicine at Oxford, and President of the Medical Council of Great Britain, and attended by Lord Stanhope, Sir William Gull, Sir Rutherford Alcock, Mr. Erichsen, Dr. Guy, and many other distinguished surgeons and physicians.

A paper was read by Sir Charles Trevelyan, presenting a comprehensive view of the subject, afterward published; and the following resolution, moved by Sir William Gull, was carried unanimously:

"That the improvement of the people of London, in health and habits of thrift and independence, demands that, while on the one hand, out-patient departments should be regulated so as to secure the prompt treatment of cases requiring the special resources of a hospital, on the other, free dispensaries should be converted into provident dispensaries, and new provident dispensaries should be established in proportion to the wants of the population."

In some respects, at least, they seem "to do these things better" in England, for happily the present agitation has resulted in corresponding efforts on the part of the hospital authorities.

Last autumn Sir Sidney Waterlow, treasurer of St. Bartholomew's Hospital, convened a meeting of the trustees, chairmen, and treasurers of all the general hospitals, at which it was agreed to make inquiries respecting their out-door departments.

This action resulted in a meeting held at the house of Sir T. Fowell Buxton, on March 21, 1879, which was largely attended by the leading medical men of London.

It was stated by Mr. E. H. Lushington, treasurer of Guy's Hospital, that about 600,000 people came annually to thirteen of the best hospitals in London for medical advice and assistance, at a cost for medicine of £15,000 per year. The average attendance of these patients varied from three to seven hours before each could be attended to, and the rush was so extreme that the medical advice they received was almost perfunctory.

At the same meeting Sir C. Trevelyan, in the course of his remarks upon the same subject, stated that statistics which had been already gathered, proved that "of 600 patients who reported annually to five or six

of the larger hospitals, two-thirds ought not to be patients at all; they were trumpery cases of colds, indigestion, and imaginary ailments."

I fear, Mr. Editor, that I have already trespassed upon your space in this effort to show what has been done and what is being done abroad.

It is true the evil is greater in London than in New York, but is it not well to be wise in time.

I firmly believe the "way out" is by the establishment of true provident dispensaries.

Respectfully yours,

HENRY E. CRAMPTON, M.D.

221 SECOND AVE., N. Y., July 23, 1879.

SACCHARATED CHLORO-PEPSINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—After a somewhat extended experience with a comparatively new preparation, let me give the readers of "THE RECORD" the results of my observation.

Last summer my attention was attracted to the claims of saccharated chloro-pepsine. Although I had previously been partial to cerium oxalate in the treatment of nausea and vomiting in pregnancy, and as a gastric sedative in other forms of nausea and vomiting, I determined to give the new compound a fair trial. I have had every reason to be well pleased with its action, and have found it equally as efficacious as the cerium alone; in some cases more so, and it possesses the advantages of aiding digestion, preventing "acidity," preserving the appetite, and being palatable.

Extending its field of operation, I tried its effects in a case of nausea, vomiting, and anorexia due to chronic alcoholism. After prescribing other remedies (stomachics, simple pepsine, gastric sedatives) with indifferent effect, as soon as I ordered the saccharated chloro-pepsine improvement began, and the affection promptly disappeared. The same remedy proved equally potent in relapses.

Last summer (especially during the month of August) I tested the value of saccharated chloro-pepsine in infantile summer complaint. In cases where mother's or diluted cow's milk is rejected by the stomach or passed *per anum*, or both, wherein the stools are frequent, green, acid, and ill-odored, this preparation, in conjunction with prescribed nourishment (lime-water or Vichy water, and milk, raw meat, or raw meat-juice), acted very promptly. Immediately its use was begun vomiting ceased, and the stools gradually underwent a change as regards frequency, color, odor, etc., till in a short time the complaint was cured.

As a general remedy in the large proportion of these cases, either alone or combined with minute doses of pulv. rhei, saccharated chloro-pepsine has given me happy results.

Sprinkled upon a teaspoonful of milk or meat-juice, children take it very readily.

Simple pepsine and lacto-pepsine have not afforded as much satisfaction.

The peculiar value of saccharated chloro-pepsine seems to reside in the combination of the pepsine with the other ingredients, whereby a sedative and tonic effect is manifested upon the stomach and bowels in addition to the digestive power of the pepsine.

Unfortunately, it is a proprietary preparation. Inasmuch as its formula is public property, the former

fact need not deter the progressive physician from employing a remedy of much value for certain affections.

FRANK D. BEANE, M.D.

NEW YORK.

THE NATIONAL BOARD OF HEALTH AND HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In your issue of June 28th was a communication relative to the "National Board of Health and Homœopathy," which it seems to me requires a reply—not for the purpose of discussing the appointment of a homœopath to such a position, but with the intention of showing what claims those calling themselves homœopaths have to such a distinctive title, and whether they are faithful to the principles they profess.

The implied and expressed wish of B. is a reconciliation of the two sects; more explicitly he desires that orthodox medicine recognize the claims of homœopathy to be considered as a legitimate and distinct school of medicine worthy of notice. If any person ought to know and understand the principles and practice of that doctrine, surely it is the founder thereof, *i.e.*, Hahnemann. Now he distinctly and plainly states that (1) the law of *similia similibus curantur* is the *only* fundamental law of therapeutics; (2) the efficacy of medicine is increased by extreme attenuation or dilution; (3) psora is the cause of the majority, if not all of the chronic diseases.

To these cardinal doctrines, therefore, any person claiming to be a disciple of his must subscribe and adhere unto in practice and precept; for without this confession of faith he can have no claim to the name of homœopath.

Let us see, by taking their own words as evidence, whether any now deserve the name. First, your correspondent B., whom I believe to be a good exponent of the doctrine as it now exists, says: "Very many . . . are educated men, educated in both schools, graduate side by side with us . . . yet because they choose to administer their remedies according to the law of *similia* instead of *contraria* . . . we ostracize them. . . . Their practice is no more based upon an exclusive dogma than ours; their educated men do not reject the accumulated experience of the profession . . . their anatomy, physiology, pathology, and organic chemistry are the same as ours; they use the same palliatives as we do. The only point upon which we differ is the administration of remedies."

In reply to this I would say that we do *not* ostracize them for administering remedies according to the law of *similia*, but because they attempt to trade upon a name; and, if their precepts differ in no essential particular from ours, what right have they to that special name? One of the best homœopathic authorities, J. Kidd, says in his *Laws of Therapeutics*, page 33, "Truth is greater than Hahnemann, and of late years his speculations about psora and infinitesimal doses have been tacitly given up by all the most skilful and intelligent of his followers. . . . Adopting with great delight the doctrine of *similia similibus curantur* as the chief, though *not* the *only* foundation for therapeutics, I learned for myself that diseases which too often remained stationary under treatment by globules, were most effectually and quickly cured by tangible doses of the same medicines which failed to

cure when given in infinitesimal doses." Also from the same work, the following extract from an address before the Hahnemann Society in Cincinnati, in 1875: "Some people suppose that a physician professing belief in homœopathic law is obliged to limit his practice to the application of that law. . . . The man, however, who is loyal to nature and to truth regards such restrictions as sheer impertinence, and claims *everything* which cures, be the process explainable or not . . . and if he finds any residuum of truth or usefulness in allopathy or any other system, asks no man's permission to use it."

In 1877, when the homœopaths of Great Britain were making an effort to be admitted to fellowship with the regular profession, the following was written to Dr. Richardson by a leading homœopath: "It is unwise and incorrect to assume the title of homœopath, since we make frequent use of remedies of a simpler kind, such as occasional aperients, anodynes, opiates, anæsthetics, tonics, galvanism, hydropathy, Turkish baths, and mineral waters; finally, the use of the infinitesimal is practically all but abandoned." The leaders of the sect in London also subscribe to the following: "We, the undersigned, believing medicine to be . . . &c. Therefore, the adoption of any theory or practice should not exclude any medical man from the freest professional intercourse, *provided* he does not trade on a distinctive name, nor unprofessionally advertise his mode of practice."

All this certainly is explicit and conclusive. I have shown that the intelligent and educated homœopathic practitioners have practically given up every shred of homœopathy save what they are pleased to call the law of similars; also, that most, if not the entire amount of credit which the system of "cure by causation" and infinitesimal doses has attained, has been accomplished by the success of men who, calling themselves homœopaths, practised precisely as other physicians do; but to the laity homœopathy still means infinitesimal doses, and to them the charm of novelty has set up a claim to credit totally undeserved. The law of *similia* as well as that of *contraria* is rejected by the regular profession. Therapeutics cannot now be elevated to, nor do its most enthusiastic teachers claim for it, the dignity of a science. So far as that appellation is applicable, it is still in the primary stage of observation; and here for the present it must remain, giving no adherence to any law, but to the knowledge alone that experienced and skilled investigators have gathered and still are accumulating, which is applied tentatively to each case as it comes before us.

This, however, is not science, for we cannot predict the result by either an algebraic equation or the differential calculus. The human frame is infinitely various, and its limits and variations we know not. Why then should doctrines so crude as those proposed for our acceptance by the homœopaths be received? They make a pretence of still holding fast to the law of similars. What law of similars, and by whom educed? is the query. The answer is far from satisfactory. Their so-called proofs are worthless; but even were they not, the method of investigation pursued has little homœopathic save its absurdities.

In direct contradiction to "B.," I would assert that they have *no* pathology. To a TRUE homœopath, disease, however complicated, is nothing but a bundle of symptoms to which he has only to fit a remedy causing the same succession of sequences as the malady, and the cure is wrought.

Therefore I say, that though there is less of intolerance and more liberality of feeling existing now than

formerly, so long as the alleged followers of Hahnemann arrogate to themselves a distinctive system and name, and unprofessionally trade upon it, so long will orthodox medicine refuse to receive them into its ranks.

G.

OAKLAND, CAL.

Obituary.

REUBEN SPENCER CHAPIN, M.D.

DR. REUBEN SPENCER CHAPIN, a licentiate of the Medical Society of the State of New York in 1849, made an Honorary M.D. of the same society in 1864, died at his residence, 238 East Eighteenth Street, in this city, on Saturday, the 2d inst., in the sixty-second year of his age.

Dr. Chapin was a native of Somers, Conn., where his remains will be taken for burial.

During the last ten years he has suffered from disease of the spine, which became so severe in March last that he was compelled to abandon his practice. He was favorably known, and for many years held the position of warden and treasurer of Grace Chapel, East Fourteenth Street, in this city.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 27 to August 2, 1879.

CORSON, J. K., Capt. and Asst. Surgeon. Leave of absence extended one month, with permission to go beyond the limits of this Division. S. O. 84, Div. of the Pacific, and Dept. of California, July 21, 1879.

KANE, J. J., 1st Lieut. and Asst. Surgeon. To proceed to Santa Fé, New Mex., and report to Commanding Officer, District of New Mexico, for assignment to duty. S. O. 144, Dept. of the Missouri, July 26, 1879.

BREWSTER, W. B., 1st Lieut. and Asst. Surgeon. To report in person to the Commanding Officer, Fort Robinson, Nebr., for duty. S. O. 64, Dept. of the Platte, July 26, 1879.

APPEL, A. H., 1st Lieut. and Asst. Surgeon. To report to Fort Peck, and report thence by letter to Col. N. A. Miles, 5th Inf., for duty. S. O. 81, Dept. of Dakota, July 24, 1879.

THE NEW MARINE HOSPITAL ON BEDLOE'S ISLAND.—The Marine Hospital Service is now establishing a hospital for itself on Bedloe's Island. This island is located in the harbor about a mile below the Battery. It has heretofore been occupied and garrisoned by the War Department. During the war a large hospital existed there, and there are now buildings upon it suitable for a hospital of about one hundred and fifty beds. Three surgeons will be in attendance, Dr. C. F. Ellinwood being surgeon-in-charge. A steam ambulance will connect it with the city. The Marine Hospital Service treats about twenty-five hundred cases a year at this port. Heretofore the patients have been distributed amongst the different hospitals of New York and Brooklyn, the greatest number going to Seaman's Retreat Hospital on Staten Island, and to New York and Brooklyn City Hospitals.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending August 2, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
July 26, 1879.	0	4	49	1	36	24	3	0
Aug. 2, 1879.	0	5	34	3	44	19	1	0

THE YELLOW FEVER.—Advices from Memphis bring the intelligence that the yellow fever in that city has not yet been declared epidemic. In a former item we stated that according to rule, given by the President of the Board of Health, the disease would be declared epidemic when it caused a weekly mortality greater than that from all other diseases. That point has been reached, but the National Board of Health ordered that it be not declared epidemic, as there was no rule governing such action. The total number of cases to Aug. 6th, are 261; total number of deaths, 74. The disease lingers in the places where it was most severe last year. Physicians are sanguine that the maximum death-rate has been reached.

The disease is in New Orleans, but has shown no disposition to spread rapidly, and hopes are entertained that it will confine itself to one portion of the city. Aug. 6th—Not a suspicious case has developed since July 30th. The victory of sanitary measures seems assured.

On August 2d, two cases from Havana were sent to Lower Quarantine at this port. There are now five cases of yellow fever in the hospital on Swinburne Island, Lower Quarantine. Thirty vessels are now under the supervision of Dr. S. O. Vander Pool, Health Officer. All are from infected ports, most have discharged their cargoes and will be loaded with outward freight while lying at anchor in the bay. One case of yellow fever found its way to one of our hospitals, wherein the patient died, but additional precautionary steps have been taken so as to prevent the repetition of such an unpleasant occurrence.

The authorities of Rome have declared quarantine against all vessels arriving from America, on account of yellow fever in this country.

HAVANA.—The total number of deaths in Havana from yellow fever during the month of July was 537, against 504 for the same month last year. Since the beginning of the year 857 deaths from yellow fever have occurred here, against 813 for the same time last year.

VOLUNTEERS FOR YELLOW FEVER SERVICE.—The order detailing Surgeon W. K. Schofield for inspection duty at Matanzas, Cuba, under the National Board of Health, has been revoked, and Medical Inspector Somerset Robinson is ordered there in his place.

THE BRITISH MEDICAL ASSOCIATION held its forty-seventh annual meeting this week at Cork, on the 5th, 6th, 7th, and 8th insts., R. W. Falconer, M.D., presiding. An address in medicine was delivered by Alfred Hudson, M.D., Professor of Physic in the University of Dublin; an address in surgery by W. S. Savory, M.B., Lecturer on Surgery at St. Bartholomew's Hospital; and an address in public medicine

by Andrew Fergus, M.D., President of the Faculty of Physicians and Surgeons of Glasgow.

The business of the Association was transacted in six sections, including one on public hygiene and one on psychology. In addition, there was a subsection on ophthalmology and otology, presided over by Mr. Jonathan Hutchinson, and one on dermatology, presided over by Prof. McCall Anderson.

A number of American physicians read papers and took part in the discussions.

Dr. Geo. M. Beard read a paper on "Inebriety and Allied Nervous Diseases in America;" Dr. L. A. Sayre opened the discussion on "The Diagnosis and Treatment of Joint Diseases;" Dr. L. Turnbull, U.S.A., discussed "Tinnitus Aurium;" Dr. E. Seguin read a paper on "The Psycho-Physiological Training of an Idiot Hand."

The Association was hospitably entertained by the city, and its work was interspersed with numerous excursions and receptions.

POWDERED ALUM IN THE TREATMENT OF POST-PARTUM HEMORRHAGE.—Dr. Clinton Cushing, of Oakland, Cal., suggests the use of powdered alum in the treatment of post-partum hemorrhage, and bases his recommendation upon the success obtained in the following case: Mrs. B., multip., æt. 37, nervous temperament, general health good, previous deliveries uncomplicated, was taken in labor, which terminated in the birth of a healthy child at the end of six hours. Chloroform, not to exceed two drachms, was inhaled during the last half-hour; the placenta delivered itself promptly; the uterus contracted firmly; and, according to his usual custom, within two or three minutes a teaspoonful of the fluid extract of ergot, with one-sixth of a grain of morphia, were administered. Within ten minutes her face was noticed to be deathly pale, her pulse was imperceptible, the bed was deluged with blood, and the vagina was filled with clots. The doctor introduced his hand into the uterus, which was completely relaxed, and no symptoms of contraction could be induced by combined external and internal manipulation and pressure. The woman was nearly moribund; blood was still oozing away. Cold water poured upon the abdomen from a height gave only negative results. He had no astringents, and there was no ice at command. A package of powdered alum was found in the house, from which he took a handful, closed his hand, introduced it into the uterus, opened his hand, and then spread it over the entire inner surface of the relaxed organ. The effect was immediate; the uterus quickly and firmly contracted: all bleeding ceased, and it did not return. Convalescence was slow, but satisfactory. There was no secretion of milk. The lochia was normal. The after-pains were only slight. The remedy was used "on the spur of the moment," and with a happy result.

REPORT OF PENNSYLVANIA HOSPITAL FOR THE PAST YEAR.—The report of the Board of Managers of the Pennsylvania Hospital for the year ending the 1st of May, 1879, states that in all the departments of the Pennsylvania Hospital 2,144 patients were treated, and 4,122 out-patients, making an aggregate of 6,266 persons relieved, at a cash outlay of \$239,870.74. The number of patients during the year was 620, and 400 remained under care at the close of the report. The report states that since the opening of this branch of the General Hospital, thirty-eight years ago, 7,867 patients have been successfully treated; about 54 in every 100 being males, and 46 females. The expenditure for both branches dur-

ring the year was \$188,851.82, which is a slight excess over expenses, of which \$25,004.35 was paid for the support of 53 free patients; besides the free patients many persons have been maintained at a rate less than the average cost of a patient, and the impaired means of support of many of the inmates have caused applications for a reduction of board to be made, which, in proper cases, have been favorably considered; though these concessions were unavoidable, no reduction has been made in the liberal system of maintenance beyond what a prudent economy demands.

The records of the Pine Street Hospital show that 1,672 patients occupied beds in the wards; that 1,524 new cases were received, and 130 now remain under treatment. The entire income from the endowment fund, with other receipts by the treasurer, amounting to \$48,370.19, have been spent in this department. Its expenses amounted to \$51,018.82.

The Out-patient Department reports: New surgical cases, 3,027; new medical cases, 1,095—total new cases, 4,122. Surgical visits, 18,690; medical visits, 2,409—total visits, 21,099. The increase of cases in the year was 294; of visits, 3,232. The number of cases treated in this department since its opening in November, 1872, is 20,097.

The report also states that the Board have arrived at a plan of introducing women student nurses from the pupils of the Women's Hospital into the wards. Each nurse is to remain in the wards twelve months, entirely under the control of the Board, at a compensation of \$13 per month. A thoroughly instructed woman has also been employed as superintendent of the nurses in training, in order that the plan may be rendered thoroughly effectual.

Some applications have been made to know if the Hospital will take charge of invalids needing medical attention for the residue of their lives, with the view of providing them with the comforts of a home. This subject has engaged the attention of the Managers with the hope of organizing a system which may prove to be a valuable aid to the public, and within the proper limits of the design of the hospital.

PUERPERAL CONVULSIONS AND POST-PARTUM HEMORRHAGES.—There have recently been a number of additions to the therapeutics of these conditions. A writer in the *MEDICAL RECORD* has used jaborandi very successfully for puerperal convulsions. In an article in the *Nashville Journal of Medicine and Surgery*, galvanism is claimed to have given equally good results. Fifteen cells were used, the negative pole applied to the os uteri, and the positive to the dorsal and lumbar region. The current was kept up for over an hour.

For post-partum hemorrhage vinegar is extolled very highly by Dr. Penrose in the *Ohio Medical Recorder*. He considers it both antiseptic and astringent. He applies it by saturating a rag with the vinegar, carrying this to the cavity of the uterus, and squeezing it. A writer in the *Ohio Medical Press and Circular* uses a rubber bag with a tube and stop-cock. He inserts the bag into the uterus, and then fills it with warm water; as the uterus contracts it empties the bag. A third method of procedure in these cases is to invert the body while friction and other excitants to uterine contraction are employed.

Dr. THOMPSON, of San Francisco, is in London, showing the profession there his new method of replanting teeth. It is said that he takes them out, keeps them in warm cotton while he fills them or builds them up, and then replaces them.

Original Lectures.

CLEFT PALATE AND ITS TREATMENT.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

By JOHN ASHURST, JR., M.D.,

PROFESSOR OF CLINICAL SURGERY.

GENTLEMEN—The patient whom I bring before you to-day is suffering from a congenital affection which, though not very common, is sufficiently often met with to render it important for you to be familiar with its pathology and with the means by which it may be remedied. This young man has come from some distance to obtain treatment for a fissure, or cleft, involving the whole of the soft palate, and the operation by which I hope to relieve him is that which is known as staphylorrhaphy, and is a good example of a surgical procedure which, in its modern and successful form, is definitely based upon accurate anatomical and physiological knowledge.

Cleft palate, as no doubt many of you know already, may vary in extent from a slight fissure, involving the uvula only (in which case it is also designated as *bifid uvula*), to a gap implicating the whole of both soft and hard palates, and not unfrequently further complicated by the co-existence of single or double harelip. Unlike the latter deformity, the fissure in cleft palate occupies the median line, except when placed in the extreme anterior part of the mouth, when it passes through the alveolus into one or other nostril, or, in some cases, into both—the so-called intermaxillary bone, attached to the vomer, then projecting into the cleft, and dividing it, as it were, into two parts. Cleft palate is, of course, congenital, and is occasionally hereditary; when not accompanied with harelip, it is often unnoticed during infancy, though sometimes, in its worst forms, by permitting regurgitation of food through the nose, it interferes seriously with nutrition, and then becomes a matter for the surgeon's grave consideration. Usually, however, it does not excite much attention until the child is old enough to talk, when, by preventing distinct enunciation and imparting a peculiar nasal tone to the voice, it leads to an inquiry as to the possibility of obtaining surgical relief.

The age at which an operation may properly be attempted for the closure of a cleft palate is a matter on which some difference of opinion exists. Until within a comparatively few years it was an accepted doctrine that no interference should be recommended until the patient had acquired sufficient age to earnestly desire relief, and to co-operate with the surgeon in the operation and after-treatment. Without the aid of anaesthesia, staphylorrhaphy was a very tedious and painful procedure; and even when the operation had been completed, great fortitude and constancy of purpose were requisite on the side of the patient to keep the parts at rest until union should occur. The unfortunate sufferer was not permitted to talk, eat, or drink, nor even to swallow his saliva, which was allowed to dribble from the mouth, lest the act of deglutition should break up the newly formed adhesions. Even as lately as 1867, Dr. J. Mason Warren, who had probably a larger experience in the treatment of cleft palate than has fallen to the lot of any other American surgeon, had operated but once on a young child, and expressed the opinion that it was generally

necessary to wait until the patient was old enough to fully appreciate the importance of the treatment pursued, and to submit patiently to pain and inconvenience, adding that this was "one of the very few operations" in which the use of anaesthetics was inadmissible. A similar view was for many years entertained by Sir William Fergusson, who, however, ultimately became convinced that the operation might properly be performed at an early age, and that the patient need not be denied the benefit of anaesthesia.

The advantage of an early operation is that if the fissure be closed before the patient has learned to talk, the nasal tone of voice which is so characteristic of cleft palate may probably be avoided; whereas, after an operation in adult life, the improvement in articulation is often very slow, and sometimes much less marked than may have been expected. On the whole, I am disposed to agree with Mr. Holmes upon this subject, and am in the habit of recommending that an operation should be attempted when the child is three or four years old.

Several distinct forms of operation have been suggested for the cure of cleft palate: one, which, under the name of *staphyloplasty*, has been recently recommended by Schönborn, a German surgeon, consists in taking a flap of mucous membrane from the posterior wall of the pharynx, and fixing it between the freshened edges of the cleft; but the operation which is generally adopted, and which I intend to employ in the present case, is a simpler, and, as it seems to me, altogether a more practicable procedure, and is designated, when applied to the soft palate, as *staphylorrhaphy*, and when to the hard palate, as *uranoplasty* or *uraniscoplasty*. Again, Lannelongue, a French surgeon, has closed a cleft of the hard palate by bringing down the nasal mucous membrane; while, in cases of *bifid uvula*, my friend and colleague at the Episcopal Hospital, Dr. Forbes, has ingeniously imitated Nélaton's operation for harelip, surrounding the fissure with an inverted Δ incision, and allowing the flap thus formed (which remains attached at both ends) to drop so as to form a diamond-shaped Δ wound, which then readily closes by granulation.

I have told you that the success of the modern operation of staphylorrhaphy is due to the procedure being based upon a careful study of the anatomy of the parts concerned, and to Sir William Fergusson is, I think, undoubtedly due the credit of having first clearly indicated the essential points of the operation. *Staphylorrhaphy* owes as much to Fergusson as *uranoplasty* does to Warren. I will not say much to you in regard to the latter operation, as it is not required in the case before us, and as most of you are no doubt familiar with it from your didactic lectures. I will merely remind you that Warren's operation consisted in dissecting up the mucous covering of the hard palate from either side of the fissure, and uniting the flaps thus formed in the median line; that Langenbeck modified this procedure by including the palatal periosteum in the flaps, so as to utilize the bone-producing quality of that structure; and that Fergusson, in his later years, reviving a suggestion of Dieffenbach's, divided the entire thickness of the hard palate on either side with a chisel, and then pressed the segments together, and held them in position with wire sutures.

The history of *staphylorrhaphy* is one of much interest, and it is curious to notice how various improvements were empirically and tentatively introduced by different surgeons, before Fergusson's demonstration of the anatomy of the palate showed clearly

how a successful result was to be sought for. The first attempt to cure cleft palate by operation appears to have been made by a French dentist, M. Lemonnier, about the year 1760; but, though the experiment was subsequently repeated in two or three instances, staphylorrhaphy did not become an established operation in surgery until after the occurrence of Roux's famous case, in 1819, just sixty years ago. Roux's patient was a student of medicine, a Canadian named Stevenson; and so wonderful, it is said, was the improvement in his speech after the operation, that his friends with difficulty recognized him as the same individual.

A year or two afterward, Dr. John C. Warren, of Boston, operated successfully for cleft palate in a girl of sixteen, and since then staphylorrhaphy has been practised and improved by numerous surgeons both at home and abroad. Among those who in our own country have particularly illustrated this branch of surgery, I may mention, without wishing to make invidious distinctions, the Warrens, father and son, in Boston; Mettner, of Virginia; Hosack and Stevens in New York; and Mütter and the elder Pancoast, in this city.

Though the operation was often, it was by no means invariably, successful; and Velpeau, writing in 1839 (twenty years after the occurrence of Roux's first case), refers to a young girl who had been operated on *five* times without benefit, and mentions several fatal cases as having occurred in Roux's own practice.

It was soon found that, though a skilful surgeon could without much difficulty bring the edges of the cleft together with stitches, yet it was almost impossible in many cases to keep the parts sufficiently long in apposition for union to occur, the tension upon the sutures being often very great, and the involuntary motions of the patient tending inevitably to make the cleft reopen. Hence Roux introduced the practice of making a transverse incision on either side, along the edge of the hard palate, separating the *velum pendulum* for a short distance, and thus allowing its halves to drop together in the median line. Dieffenbach improved upon this plan by making longitudinal incisions, four lines distant from the edges of the cleft, so that by the gaping of these wounds the tension on the stitches should be lessened. Mettner substituted for the single incisions of Dieffenbach, numerous small incisions, not all in the same line, and various forms of lateral incision were also resorted to by Liston, Mütter, Pancoast, and other surgeons.

Mason Warren, in 1843, described an important modification of staphylorrhaphy, which consisted in dividing the posterior pillars of the fauces, and finally, in December, 1844, Fergusson, in a paper read before the Royal Medical and Chirurgical Society of London, and published in the transactions of that body for the following year, showed, from a careful study of the anatomy of cleft palate, that while in the act of deglutition the separated halves of the palate were thrust together by the action of the superior constrictors of the pharynx, the action of the levatores palati and palato-pharyngei tended to draw them asunder, and that hence a division of these muscles would obviate the chief risk of failure in the operation, while after such division the patient might take nourishment freely and without danger, since the action of swallowing would then serve rather to approximate than to separate the parts concerned.

I lay stress upon these points, because efforts have been made to take from the late Sir William Fergusson the credit which is justly his due in relation to this

matter. Undoubtedly great success had been obtained before his demonstration was made public, by Warren and Mütter, in this country, and by other surgeons in Europe, but the success was not by any means constant, and the mechanism by which it was obtained was not understood. Fergusson's mode of practising the necessary myotomy was by introducing a curved knife through the cleft, and cutting the levator palati on either side from the nasal surface, the palato-pharyngei being afterward divided, if thought necessary, by cutting the posterior pillars of the fauces with blunt-pointed scissors, as in Warren's operation. Another plan of proceeding has been introduced by Sédillot, of Strasbourg, and consists in dividing the levator palati by transfixing the palate from below—varying, in fact, the longitudinal incisions of Dieffenbach by placing them more outward and backward—and this plan has been further usefully modified by Pollock, in England, and Guérin, in France, by making the incisions, as it were, "sub-mucous," transfixing and making a sweeping cut from above downward, so as to sever the muscles while respecting the buccal mucous membrane. Still another plan is recommended by Bryant, based apparently on a suggestion of Mr. Francis Mason, and consists in cutting loose the palate on each side, from behind forward, so that when the edges of the cleft have been approximated the whole organ resembles a large uvula.

The operation of staphylorrhaphy may be considered as divided into three stages, which are respectively (1) the myotomy, (2) freshening the edges of the cleft, and (3) the introduction and securing of the sutures. If Fergusson's plan is to be followed, the myotomy must be either the first or second step of the procedure, and, as this part is sometimes attended with considerable bleeding, it may even be thought well to adopt Callender's suggestion, and divide the muscles on the day previous to that fixed for the remainder of the operation. If, which I prefer, Pollock's modification of Sédillot's plan is to be chosen, the myotomy may be conveniently made the last stage of the operation, or at least may be postponed until the sutures are in place, though they may not have been tightened.

Should the patient be anaesthetized? I have no hesitation in answering this question in the affirmative. I have assisted in staphylorrhaphies performed without the aid of ether, and can testify that under such circumstances the operation is very tedious and painful, and one which is followed by a good deal of shock and exhaustion.

In what posture should the patient be placed? If an anæsthetic be not used, it is customary to adopt a sitting or semi-reclining posture, as better enabling the patient to clear his mouth of blood by spitting; but when ether is employed, the supine position is much more satisfactory, affording a better view of the parts (at least in a room lighted, like this amphitheatre, from above), and allowing the head to be kept perfectly steady during the surgeon's manipulations. There need be no trouble from bleeding if you have an assistant for the special duty of keeping the mouth clear by means of small sponges mounted on sticks.

Great advantage may be derived from the employment of a gag to keep the mouth widely open, and one of the best of the several ingenious instruments which have been devised for the purpose is that which I show you here, and which bears the name of Professor John Wood, of King's College Hospital. To dispose of the patient's tongue, which must be kept out of the operator's way, I know of no better plan than to pass a loop of ligature-silk through its tip, and intrust the

ends (which should be tied together) to an assistant to hold firmly on one side.

For freshening the edges of the cleft, you may employ either a slender knife or scissors. For my own part, I prefer the former instrument, as I do also in the somewhat analogous operation for vesico-vaginal fistula, though I have no wish to deery the value of the scissors in the hands of those who find them more convenient. I find that with the knife I can work more quickly, and I think that it causes less bruising of the tissues.

Your stitches may be of silk, horse-hair, wire, or, indeed, of any material that you may fancy; I do not know that it makes a great deal of difference; but, upon the whole, I prefer a moderately thick silver wire, fastened by clamping on it a tolerably large perforated shot, which is less apt to bury itself in the tissues than one of smaller size. Various complicated instruments have been devised for the introduction of the sutures—some of them, indeed, might pass for portable sewing-machines; but a small, well-curved needle answers every purpose, being held with suitable forceps if silk is to be used, or mounted on a handle if you are going to employ the wire suture. The needles which I show you, and which I intend to use to-day, are, as you see, adapted one for the right and the other for the left side of the palate, and are meant to be passed from below upward, and threaded, after introduction, through the cleft.

While I have been talking to you, our patient has been etherized, and I will now proceed to the operation, trusting that the explanations which I have given will enable you to follow the various steps of my manipulation, of which, unfortunately, most of you will be able to see but little. Having introduced the gag and secured the tongue in the way which I have described to you, I catch one-half of the split uvula with forceps, and, transfixing the edge of the cleft near its angle, cut backward so as to separate a thin shaving of tissue; the same thing is repeated upon the opposite side, and finally the angle of the cleft itself is pared, the mucous membrane being thus removed in one continuous strip. I next introduce four sutures, passing first the left-side needle, which Dr. Hunter threads for me as soon as its eye appears in the cleft; then withdrawing it and repeating the same process on the right side, and intrusting the wires, as each suture is introduced, to an assistant, until all are in place. The next step is the myotomy, which may conveniently be accomplished before the stitches are tightened. Asking my assistant to make the left side of the palate tense by drawing upon the left-hand wires, I transfix it with a double-edged knife just in front and to the inner side of the hamular process, which can be readily felt within and a little behind the position of the last molar tooth. In doing this I take care to direct the point of the knife toward the median line, as an outward thrust might endanger the important vessels in that situation. After transfixion, I carry the handle of the knife upward, so as to depress its blade, which I then withdraw with a sweeping cut, in such a way as to divide the levator palati freely, while saying as much as possible the mucous membrane of the mouth. Repeating the same procedure upon the opposite side, I find that the palate is so thoroughly relaxed that it will not be necessary in this case, I think, to divide the palato-pharyngei.

All that remains to be done, therefore, is to tighten the sutures and fix them by clamping upon the ends of each wire a perforated shot. The patient will be cautioned against talking, coughing, or even swal-

lowing, unnecessarily; but he will be supplied with abundance of nutriment in the form of milk, and the line of sutures will be brushed over every day with a ten-grain solution of nitrate of silver, which, I think, assists the healing process.

[The sutures were removed, beginning with the most anterior, from the fifth to the eighth day, when the whole palate was found to be firmly united, with the exception of a small space in front, which rapidly contracted and healed by granulation. The patient returned to his home, entirely well, on the fifteenth day after the operation.]

Original Communications.

THE HISTORY OF MASSAGE.

By DOUGLAS GRAHAM, M.D.,

BOSTON, MASS.

PART I.

IN almost every city of the United States, and, indeed, of the whole civilized world, there may be found individuals claiming mysterious and magical powers of curing disease, setting bones, and relieving pain by the immediate application of their hands. Some of these boldly assert that their art is a gift from Heaven, due to some unknown power which they call magnetism; others designate it by some peculiar word ending with *pathy* or *cure*, and it is often astonishing how much credit they get for their supposed genius by the most learned people of the land outside of the medical profession. History informs us that rubbing, kneading, percussion, passive and resistive movements have been partly used, in some form or other, among savage and civilized nations, from the most ancient times. To express these various manœuvres collectively, nearly all physicians who take any interest in the matter, foreign as well as American, seem satisfied with the French word *massage*, from the Greek *masso*, I knead or handle. But so little attention has this subject received, that Prof. Billroth, of Vienna, in 1875, and Dr. Wagner, of Friedberg, in 1876, stated that there were many physicians in Germany who had never heard of massage, and that it was then an every-day question as to what it meant, some even supposing that Dr. Mezger, of Amsterdam, was the originator of it.* Therefore, it is no wonder that when an article appears on the subject it often gets the credit of being original by many who read it, but overlook the fact expressed so well in the words of Hippocrates, that "Medicine hath of old both a principle and a discovered track, whereby in a long time many and fine discoveries have been discovered, and the rest will be discovered, if any one who is competent and knows what hath been discovered, start from these data on the search. But whoever, rejecting these, and despising all, shall undertake to search by a different track and in a different manner, and shall say that he hath discovered something, will be deceived himself and will deceive others." It is nothing unusual to see clear-headed individuals, uneducated as well as those of extensive learning, evolve from their inner consciousness, so to speak, something

* Vide Wiener med. Wochenschrift, No. 45, 1875; Berliner klin. Woch., Nov. 6 and 13, 1876.

or other to meet the exigencies of a case, and then announce the same as a new discovery, when it had been put to similar purposes many times before. Such geniuses, if truly ignorant that their device had never before been heard of, deserve equally as great credit as the original inventors; but what very often detracts from the merits of their case is the fact that they did not stop to inquire whether any one else had ever used the same methods or not. On the other hand, it is not always the one making use of something novel who claims originality, but frequently those who are not so well informed on the subject as he is who claim it for him. In the latter category almost every one has been delighted to find himself placed at some time or other, without any such intention on his part; and it is sometimes an agreeable excuse to let it pass, on the ground that it would not be dignified to inform the admirers of their ignorance. These remarks apply to massage and its advocates, as well as to other matters pertaining to medicine.

The earliest definite information concerning massage appears at about the beginning of the fourth century B.C., in the works of the great Greek physician, the Father of Medicine, Hippocrates. Though his notions, like those of the other ancients, were vague and incorrect with regard to the circulation of the blood (the important discovery of which by Harvey not taking place until more than 2,000 years later, A.D. 1628), yet he used rubbing in accordance with scientific principles, in such a way as to aid and not retard the circulation, as is shown by the word with which he defined the process, viz., *anatripsis*—literally, the art of rubbing up, not down. In this way, doubtless, he had had experience in promoting resorption of effusions, as it is now well known that rubbing the limbs upward favors the return of the circulation, relieves blood-stasis, and makes room in the veins and lymphatics for the more speedy passage of morbid products. After the acute stage of an injury had elapsed Hippocrates applied massage, as we learn from the following words: "The physician must be experienced in many things, but assuredly also in *anatripsis*; for things that have the same name have not always the same effects. For rubbing can bind a joint that is too loose, and loosen a joint that is too rigid, and the joint must be moved about," etc.* Paradoxical as this may seem, yet I have witnessed the verification of it in two cases occurring in my own practice. They have already been reported in the New York MEDICAL RECORD for Aug. 11, 1877. The rationale of this statement, however, is not so paradoxical; for by appropriate rubbing, kneading, and passive motion, atrophied muscles, tendons, and ligaments would have their circulation accelerated and increased, and thus their nutrition and innervation improved so that they would grow larger and firmer, and, as a natural consequence, a joint too lax from such causes would become stronger. In the other case, by the same means, involuntary tension of muscles, adhesions, effusions, and hyperplastic tissue may be removed, and thus a joint stiff from such causes be made suppler.

Furthermore, says old Hippocrates in his aphorisms: "Anatripsis can bind and loosen; can make flesh and cause parts to waste. Hard rubbing binds; soft rubbing loosens; much rubbing causes parts to waste; moderate rubbing makes them grow." These words seem like revelation to any one who has had much experience in massage, and the literal fulfilment of them may be observed when the necessary previ-

ous conditions exist. Hard and soft, much and moderate are, of course, to be taken in a relative sense; for, what might be hard to one person might seem gentle to another.

Vigorous massage, as we might expect, makes soft and flabby muscles firmer. Gentle or moderate rubbing and manipulating loosens not only the abnormally tough and *matted* condition of the skin and superficial fascia, but also the involuntary tenseness of the muscles, which, if looked for, may often be found not merely locally, but generally, in overtaxed and debilitated people. Such a state of these tissues would often seem to be a physical indication of too great mental tension, which the patient, like his muscles, is unable to relax. And here comes the necessity of a careful discrimination, which Hippocrates evidently appreciated, in using massage; for, if a patient in the condition described should receive such vigorous rubbing and kneading, as is so much advocated nowadays, and which would even seem to be necessary to relax such tissues, his condition would in all probability be aggravated, for reflex action, and consequently still greater tension, would be excited by the pressure of rough friction and manipulation upon terminal nerve-filaments which are already in a state of irritation. An admirable preliminary measure to the use of massage in such cases is the warm bath, for it is grateful and soothing to the patient, solicits the blood to the surface, softens the cuticle, and removes the epithelial débris, as well as relaxes the skin, and to some extent the tissues beneath it.

"Much rubbing causes parts to waste." I have seen people who had a normal quantity of adipose tissue lose much of it, to their detriment, from the excessive use of massage. But even this feature can sometimes be utilized to advantage in cases where fat is superabundant, soft, and flabby, with a want of tone and tension in the areolar tissue. It is well known that tissues, when subjected to great and constant pressure, become attenuated and absorbed; but when acted upon by a less constant and slighter degree of pressure, they increase in thickness. "Moderate rubbing makes parts grow." This implies that the tissues to be rubbed are insufficiently nourished; and moreover, that if they be immoderately rubbed, their vitality will be lessened, their nervous irritability exhausted, and a state of congestion induced highly unfavorable to their proper nourishment.

The ancients entertained sensible views with regard to the maintenance of health. "Not only Hippocrates, but all the physicians and philosophers of that period, knew no better means of strengthening the vital principle and prolonging life than by moderation; the use of free and pure air, bathing, and, above all, by daily friction of the body and exercise. Rules and directions were laid down for giving violent and gentle motion to the body in a variety of ways—hence arose a particular art called the gymnastic; and the greatest philosophers and men of learning never forgot that the body and the soul ought to be exercised in due proportion. This art, to us almost unknown, of suiting exercise to the different constitutions, situations, and wants of man; of employing it, above all, as the means of keeping his internal nature in proper activity, and thereby rendering the causes of disease ineffectual, but also curing diseases which have already appeared, they, indeed, brought to an extraordinary degree of perfection." The gymnastics were divided into athletic, military, and medical. Herodiscus of Selivria first proposed gymnastics for the cure of disease; and to such an extent, we are

* Hippocrates, Peri Arthron. Littre, vol. iv., p. 100.

to, did he carry his ideas, that he compelled his patients to exercise and to suffer their bodies to be rubbed; and he had the good fortune to lengthen for several years by this method the lives of so many enfeebled persons, that Plato reproached him for prolonging that existence of which they would have less and less enjoyment.

Nowhere, perhaps, does the wisdom of the ancients appear more strikingly full of truth and meaning than in some of their remarks about massage. The distinguished Roman physician, Celsus, who flourished at the beginning of the Christian era, said that "rubbing should sometimes be applied to the whole body, as when an invalid requires his system to be replenished." "As rubbing is rightly applied after the cessation of an illness, so it must never be used during the increment of a fever, but, if possible, when the body shall have been wholly free from it." . . . "A paralyzed limb is strengthened by being rubbed. If certain limbs only are rubbed, long and powerful rubbing may be used, for the whole body cannot soon be weakened through a part. But when weakness of the body needs this cure over its whole extent, it ought to be shorter and more gentle. . . . Chronic pains of the head are relieved by rubbing the head itself. But far more frequently, when one part is in pain another must be rubbed, and particularly when we desire to *draw matter* from the upper or middle part of the body, and therefore rub the extremities." This is not the place to illustrate these remarks with cases treated with the modern methods of massage, though it could easily be done. However, proceeding onward with the march of time we find that one hundred years later history furnishes a good example of the truth of the first two observations here quoted from Celsus. The health of the celebrated Roman advocate, Pliny, which was never very strong, had been shaken by a severe illness the preceding year, A.D. 102. His life, he tells the emperor in one of his letters, had been in danger. He availed himself of a mode of treatment which it is presumed was much in vogue at that time. He procured the services of a medical practitioner who cured many of his patients by the process of rubbing and anointing. So much benefit did he derive from the remedy, that he asked the emperor to grant the physician, who was either a Jew or a Greek, the freedom of the city and the privilege of Roman citizenship. Cicero considered that he owed as much of his health to his anointer as he did to his physician.

In ancient times rubbing and anointing were much used in connection with the baths, the buildings for which were of great magnificence and luxury during the Roman empire, as their immense ruins yet existing testify. The Roman emperor Hadrian, seeing a veteran soldier one day rubbing himself against the marble at the public baths, asked him why he did so. The veteran answered, "I have no slave to rub me;" whereupon the emperor gave him two slaves and sufficient to maintain them. Another day several old men rubbed themselves against the wall in the emperor's presence, hoping for similar good fortune, when the shrewd Hadrian, perceiving their object, directed them to rub one another!

Martial (A.D. 100) undoubtedly refers to some kind of massage in the following lines:

"Percurrit agili corpus arte tractatrix,
Manuque doctam spergit omnibus membris."

Galen (A.D. 170) recommended friction in a great number of diseases, generally as auxiliary to other means. At Pergamus he was appointed city physician to the school of gladiators. These were rubbed be-

fore and after their exercises and combats: before, in order to increase the elasticity and strength of their limbs; after, in order to stroke away the ecchymoses, relieve the pain of the bruises, and to rest and refresh them from their fatigue.

A great deal more might be said to show that the Greeks and Romans knew well the advantages of friction as a hygienic and as a therapeutic agent. But they were not the only members of the Aryan race who practised rubbing. Strabo states that the Indians contemporary with Alexander, 326 B.C., esteemed friction highly. "In the way of exercise," he says, "they think most highly of rubbing; and they polish their bodies smooth with ebony staves and in other ways." "There are public baths in India which are associated with the practice of shampooing. The bather is extended upon a plank, and a vigorous attendant pours hot water over him, presses and bends the various parts of his body, cracks all the joints, and continues the operation of pouring, pulling and pressing for about half an hour. He then rubs him briskly by means of a hair-brush with soap and perfumes, after which the subject is obliged by his fatigue to sleep a few hours, from which he awakes extremely refreshed. The women in India take a lively pleasure in being shampooed by their slaves; and Europeans, who enter upon the process with a sort of fear, describe the sensation which results as delightful and peculiar."

Much the same practices obtain among the Turks and Arabs. With the Russians flagellation and friction by means of a bundle of birch twigs are resorted to after the subject has been well parboiled in a vapor-bath. A pailful of cold water is then dashed over him from head to foot, the effect of which is described as electrifying. After this he plunges into the snow, and thus tempers himself like steel to endure with impunity his rigorous climate. The Siberians and Laplanders also indulge in similar luxuries.

Having seen that massage has been practised after a fashion by the Greeks, the Romans, and the Hindoos, it is reasonable to suppose that it was also made use of by their common ancestors, the Aryans; so that its origin may well be spoken of as hoary with antiquity, or as some say, lost in the night of time. It may not be amiss, just here, to let history tell us who the Aryans were, and where their original place of abode was. The Aryan branch of the Caucasian race includes nearly all the past and present nations of Europe, and is that division to which we ourselves belong. The Aryans are described as being a fair-skinned, noble people, progressive, practical, and warlike, and it is said that they speedily subdued the country adjacent to them, and also the peninsula of India, 3000 years B.C. The original seat of the undivided Aryan stock was to the north-east of Persia, in the region of the Oxus and Jaxartes rivers. The water of the Oxus is said to have been extremely soft, so as to have made the skin of those who bathed in it glisten. Now, we can imagine that from the pleasant sensation of drawing the hand over the skin in admiration of the effect of the water of the Oxus upon it, may have arisen the practice of systematic friction among the Aryans.

So much for the history of massage in what might be called its period of invention. We will now briefly glance at what might be styled its period of renewal, in the sixteenth century, as but little of interest can be found worth mentioning till that time. Ambrose Paré,* in his works, which were published in 1575,

* It is narrated of Ambrose Paré, the most renowned surgeon of the sixteenth century, that when a young man he hired with a noble family to do the shaving, the surgery, and to read the family prayers,

states that friction was in great esteem in his time. He describes three kinds of frictions, the gentle, the medium, and the rough, and the effects of each. In dislocations he recommends that the joint should be moved about this and that way—not violently—in order to resolve the effused fluids and extend the fibres of the muscles and of the ligaments, so as to facilitate the reduction. From this it is apparent that he knew the influence of passive motion in promoting absorption, the rationale of which has been so well studied of late by German physiologists.

Hoffman, in his *Dissertationes Physico-Medice*, 1708, says "that exercise is the best medicine for the body." (It is not always applicable, however.) "We cannot imagine," he adds, "how much it is salutary and favorable to health; corporeal exercise excites the flow of the spirits and facilitates the excretions from the blood." He describes the passive, active, and mixed movements of the ancients, as well as the *apotherapeia* or perfect cure, meaning the last part of the ancient gymnastics, which consisted of friction, innunction, and bathing, for the purpose of obviating fatigue and curing disease.

Alpinus, in his *Medicina Egyptia*, says that frictions are so extensively used among the Egyptians that no one retires from a bath without being rubbed. "For this purpose the person is extended, then he is malaxated (manipulated, kneaded) and pressed in divers manners upon the various parts of his body. Passive motion is then given to the different articulations. They are not satisfied with *masséeing*, flexing, and extending the articulations alone; they exercise the same pressures and the same frictions upon all the muscles." The effect of which is thus described by M. Savary: "Perfectly *masséed*, one feels completely regenerated, a feeling of extreme comfort pervades the whole system, the chest expands and we breathe with pleasure, the blood circulates with ease, and we have a sensation as if freed from an enormous load; we experience a suppleness and lightness till then unknown. It seems as if we had just been born, and as if we truly lived for the first time. There is a lively feeling of existence which radiates to the extremities of the body, whilst this is given over to the most delightful sensations; the mind takes cognizance of these and enjoys the most agreeable thoughts; the imagination wanders over the universe which it adorns, sees everywhere smiling pictures, everywhere the image of happiness. If life were only a succession of ideas, the rapidity with which memory retraces them, the vigor with which the mind runs over the extended chain of them, would make one believe that in the two hours of delicious calm which follows we live a great many years."

Shakespeare has not forgotten to mention rubbing and kneading:

IAGO.—My lord has fallen into an epilepsy:

This is his second fit: he had one yesterday.

CASSIO.—Rub him about the temples.

IAGO.—No, forbear;

The lethargy must have his quiet course.

OTHELLO, iv. 1.

AJAX.—I'll knead him; I'll make him supple.

TROILUS AND CRESSIDA, ii. 3.

These lines indicate the empirical and the rational use of massage, though the latter was employed in a figurative sense.

(To be continued.)

LITHOLAPAXY, by the method of Dr. Bigelow, has been performed in New York thirty-four times, with three deaths.

PILOCARPIN IN INTERMITTENT FEVER.

By GASPAR GRISWOLD, M.D.,

HOUSE-PHYSICIAN TO BELLEVUE HOSPITAL.

THE treatment of intermittent fever naturally divides itself into measures which have in view the control of the paroxysms, and others intended to prevent the development of the malarial cachexia. For the latter purpose, the sulphate of quinine has been generally adopted by the profession; to accomplish the former, many remedies have been employed at different times, but without any very satisfactory results. It has long been held by good authorities that the development of the cachexia depends in many cases upon the occurrence of a succession of paroxysms. According to this view, the system contracts a habit of having a chill, fever, and sweat periodically; the characteristic anæmia, debility, and lassitude develop as the result of frequent exhausting pyrexias. It is well established that the prevention of the development of a single paroxysm diminishes the tendency to the occurrence of successive ones; indeed, many cases have been reported in which this alone has brought about a cure, no constitutional treatment being resorted to. That the profession has appreciated the importance of preventing a chill is well attested by the long array of measures which have been proposed for this purpose. It has been proposed to tourniquet the limbs, and thus arrest the paroxysm by preventing the congestion of internal organs. Sinapisms have been applied all over the body with the same end in view. Cups have been used over the spine, with the hope that some good result might be obtained from counter-irritation in the region of the nerve-centres. Some one has advocated the application of cold to the surface, believing that the paroxysm would be prevented by the nervous shock so produced. Others have claimed that a paroxysm might be prevented by bringing the patient fully under the influence of alcohol. Violent exercise before the hour when the paroxysm usually commenced has been said to act as a preventive by inducing diaphoresis. More often resorted to than any of the above are full doses of opium, and drachm doses of chloroform, taken internally. All attempts to prevent or abort paroxysms have been thus far so unsuccessful that treatment is now nearly always merely palliative, being simply an attempt to make the patient as comfortable as possible while he is passing through the different stages. After the paroxysm is over, quinine is given in large antiperiodic doses. If the fever be of tertian or quartan type, the next paroxysm may generally be prevented; if it be of the quotidian variety, the chances are about even that another chill will occur.

Now, what is needed is an agent which will antagonize a chill so soon after its administration that it will not be necessary to limit our efforts to preventing the occurrence of a second or third paroxysm, but will be possible to promptly cut short the first. I believe the muriate of pilocarpin to be such an agent. The essential conditions of a chill are a small, hard pulse, peripheral anæmia, and convulsive muscular contractions. Pilocarpin relaxes arterial tension, causes a determination of blood to the surface, and in the progress of the diaphoresis induced by it, brings about muscular relaxation. This theoretical antagonism receives clinical support from the following cases:

CASE I.—John H., thirty years of age, stated on admission to hospital that he had been suffering for two

weeks from malarial intermittent fever, tertian type. He said that his chill usually lasted an hour, and was followed by high fever and sweating. He had never suffered from intermittent fever before, and was not run down or anæmic. He had his first paroxysm in the hospital on the day after his admission, the cold stage commencing at 11.35 A.M. The chill was well marked, the teeth chattering, and the whole body shaking violently. Three minutes after his chill was fully developed, pilocarpin muriat., gr. $\frac{1}{2}$ was administered hypodermically. In 1 min. 40 sec. he drew a long breath, like a sigh, his convulsed muscles relaxed, and his chill stopped. A minute later his skin was moist with a slight perspiration, which went on to well-marked diaphoresis, lasting about twenty minutes. No noticeable ptialism was produced, and the diaphoresis was not more profuse than that which ordinarily follows the hot stage of a paroxysm. Forty-five minutes after the cessation of the chill the man's temperature was 99 $\frac{1}{2}$. He requested to be allowed to leave his bed, asserting that his chill was over, and that he felt all right. He complained of no fever during the remainder of the day. Patient was retained in hospital for two weeks for further observation. At the end of that time, another paroxysm not having occurred, he was discharged cured. The one dose of pilocarpin muriat. was all the treatment he received.

CASE II.—James R., thirty-six years of age, had suffered for one week from malarial intermittent fever, quotidian type. The chills generally lasted about an hour and a half. No history of malaria previous to this attack; general health good. Admitted to the hospital in the afternoon; had a well-marked chill at 9.30 A.M. on the following morning. As soon as the chill was fully developed, pilocarpin muriat., gr. $\frac{1}{2}$, was administered hypodermically. In 2 min. 50 sec. a long sigh of relief (like that mentioned in the preceding case) ushered in general muscular relaxation. Moderate diaphoresis followed, lasting about half an hour. No ptialism. Temperature 99° an hour after cessation of chill. Patient considered his paroxysm at an end, left his bed to go about as usual, and reported that he felt no fever during the afternoon. He had no chill during the next ten days, and was, at the end of that time, discharged cured. He received no treatment beyond the single dose of pilocarpin above mentioned.

CASE III.—Hans E., forty years of age, had malarial intermittent fever, tertian type, for ten days before his admission. He had had chills in former years, but seemed in fair general condition. On the day after entering hospital he had a well-marked paroxysm, which was allowed to run its course without treatment, the temperature being taken every half-hour. These temperatures are here introduced for

1ST PAROXYSM. No treatment.	2D PAROXYSM. Pilocarp. muriat., gr. 1-5, given at 10.13 A.M.
10.35 A.M. . . . T. 102	10.10 A.M. . . . T. 102 $\frac{1}{2}$
11 104	10.30 100 $\frac{1}{2}$
11.30 104 $\frac{1}{2}$	11 99 $\frac{1}{2}$
12 M. 104	11.30 99 $\frac{1}{2}$
12.30 P.M. . . . 105	12 M. 99
1 106 $\frac{1}{2}$	12.30 P.M. . . . 99 $\frac{1}{2}$
1.30 106	1 98 $\frac{3}{4}$
2 105 $\frac{1}{2}$	1.30 99
2.30 106	2 99 $\frac{1}{2}$
3 105 $\frac{1}{2}$	2.30 99
3.30 104	3 98 $\frac{3}{4}$
4 102 $\frac{1}{2}$	3.30 99
4.30 100 $\frac{1}{2}$	4 99 $\frac{1}{2}$
5 99	4.30 98 $\frac{3}{4}$

the sake of contrast. Two days afterward another paroxysm occurred. This time pilocarpin muriat., gr. $\frac{1}{2}$, was given hypodermically immediately after the commencement of the chill, and the temperature was taken as in the preceding paroxysm.

3 min. 40 sec. after the pilocarpin was given the chill ended, with the characteristic long breath and general muscular relaxation. Diaphoresis was not excessive, and there was no ptialism. Patient felt well half an hour after the administration of the pilocarpin. Remained in the hospital nine days longer without experiencing another paroxysm. Discharged cured. No other treatment than that described.

CASE IV.—Michael C., twenty-eight years of age, had suffered from malarial intermittent fever, tertian type, for twelve days before admission. General health good. Had never had chills before. Had two paroxysms in hospital, treated and observed like those in the preceding case.

1ST PAROXYSM. No treatment.	2D PAROXYSM. Pilocarpin muriat., gr. 1-5, at 11.09 A.M.
11.15 A.M. . . . T. 101 $\frac{1}{2}$	11.05 A.M. T. 102°
11.45 103	11.35 100 $\frac{1}{2}$
12.15 P.M. . . . 103 $\frac{1}{2}$	12.05 P.M. 99 $\frac{1}{2}$
12.45 104	12.55 99 $\frac{1}{2}$
1.15 P.M. 105	1.05 P.M. 99 $\frac{1}{2}$
1.45 104 $\frac{1}{2}$	1.35 99
2.15 103 $\frac{1}{2}$	2.05 99 $\frac{1}{2}$
2.45 102 $\frac{1}{2}$	2.35 99 $\frac{1}{2}$
3.15 100 $\frac{1}{2}$	3.05 99
3.45 99	3.35 99

Chill stopped 3 min. 20 sec. after the pilocarpin had been given. Diaphoresis moderate. No ptialism. Without further treatment patient experienced no more paroxysms during the next ten days. He was then discharged cured.

CASE V.—Carl G., forty-five years of age, had suffered from malarial intermittent fever every summer for several years. Present attack—quotidian type—had already lasted three weeks. Spleen somewhat enlarged, appearance cachectic. Experienced two paroxysms in hospital; these were observed and treated as described in the other cases.

1ST PAROXYSM. No treatment.	2D PAROXYSM. Pilocarpin muriat., gr. 1.5, at 10.15 A.M.
10.30 A.M. . . . T. 102	10.10 A.M. . . . T. 101 $\frac{1}{2}$
11 105	10.40 102 $\frac{1}{2}$
11.30 105 $\frac{1}{2}$	11.10 106
12 M. 105	11.40 106
12.30 P.M. . . . 104 $\frac{1}{2}$	12.10 P.M. . . . 105 $\frac{1}{2}$
1 105	12.40 105 $\frac{1}{2}$

2 107	1.40 104 $\frac{1}{2}$
2.30 106 $\frac{1}{2}$	2.10 101
3 106 $\frac{1}{2}$	2.40 103 $\frac{1}{2}$
3.30 106 $\frac{1}{2}$	3.10 102 $\frac{1}{2}$
4 105 $\frac{1}{2}$	3.40 101
4.30 105 $\frac{1}{2}$	4.10 99 $\frac{1}{2}$
5 105	4.40 99
5.30 104 $\frac{1}{2}$	5.10 99 $\frac{1}{2}$
6 102	5.40 99
6.30 100 $\frac{1}{2}$	6.10 99 $\frac{1}{2}$
7 99	6.40 99

Slight diaphoresis and marked diminution in violence of chill took place in 5 min. 40 sec. after the administration of the pilocarpin. Occasional convulsive twitchings occurred for ten minutes more. The chill stopped entirely sixteen minutes after the hypodermic had been given. The sweating caused by

the pilocarpin was very slight, and lasted only a few minutes. A well-marked hot stage succeeded the chill and terminated at about 2.30 p. m. in a sweat. The paroxysm, therefore, was not aborted; it went through its regular stages, although mitigated and lasting a shorter time. The patient remained in the wards for two weeks without having another chill, and was then discharged cured. No other treatment.

N.B.—The diaphoresis in this case was so slight that I was led to the conclusion that I had not given enough pilocarpin (my patient was a very large man, weighing over two hundred pounds). If he had experienced another chill while in the hospital I should have given him gr. $\frac{3}{4}$ instead of $\frac{1}{2}$. Perhaps a more profuse diaphoresis might have aborted the paroxysm in this case as it did in the others.

CASE VI.—Man with malarial intermittent fever, quotidian type. Chill cut short with pilocarpin. After this were prescribed ten grains of quinine in the morning, five grains at noon and evening. Recovery without another chill.

CASE VII.—Woman with malarial intermittent fever, tertian type. Pilocarpin muriat., gr. $\frac{1}{2}$ given hypodermically at about the time when the paroxysm was due, just before the chill had developed. Chill did not occur. Quinine then ordered, gr. v., t. i. d. Recovery without another chill.

From these cases it seems fair to conclude:

1st. That the muriate of pilocarpin, administered hypodermically, will promptly cut short the chill of malarial intermittent fever.

2d. That in a large proportion of cases so treated the paroxysm aborts, terminating in the sweat caused by the pilocarpin, there being no hot stage.

3d. That such abortion of a paroxysm is in itself sufficient to effect a cure in many cases.

4th. That such abortion of a paroxysm is a valuable adjunct to treatment with quinine during the intervals.

5th. That a dose of pilocarpin sufficient to produce this effect acts gently, without causing exhausting diaphoresis or unpleasant ptyalism.

The promptness with which an adequate dose of pilocarpin interrupts a chill is suggestive of its possible efficacy in cases of pernicious intermittent fever, where prevention of the full development of a paroxysm is often of the first importance.

HYDROPHOBIA.

By C. C. GODDARD, M.D.,

TEXAS.

MEPHITIC INOCULATION.

At 6 A.M., May 26th, was called to see I—W—, set 8, female. Obtained the following history from the father of the patient:

While himself and wife were absent from home, and the child was stopping with his brother's family, she was bitten Murch 15th, while sleeping on the floor of cabin, an upper lid of right eye and cheek immediately below; the latter point being only slightly abraded. She caught and held the intruder down upon the floor, until her uncle could rise from bed, and start to her rescue; she then released her hold upon it, and sprang into bed. Her uncle at the same moment ignited a match and saw it was a "skunk," which was advancing toward him with apparent evil intent; but the light evidently altered its purpose, as it slowly retreated behind a trunk in the room, where Mr. W— shot it as soon as possible.

Upon being shot, the skunk gave out its characteristic odor very strongly, so much so that they had to vacate the house soon afterwards; the odor was still very strong in the house when visited several days subsequently by the child's father.

Mr. W— excised with a knife as well as he could the bitten portion of eyelid within a half-hour after the attack.

He had no caustic to apply to wound, but applied a poultice of cactus, which applications were still being continued three days afterwards when the parents arrived, accompanied by Dr. W—, another brother of child's father.

The child's hands were lacerated somewhat while holding the skunk, but whether any of the abrasions were made by its teeth they were unable to determine definitely; but thought not.

The doctor remained some time with them, and cauterized two or three watery vesicles that made their appearance on the cheek near the eye; but whether these vesicles were produced by the poison or by the cactus-briers, he (the father) was unable to state, but thought the latter, as there were several of same character upon the forehead afterwards, produced evidently by cactus-points.

The wound healed nicely, and after a few days, during which time she was somewhat depressed (knowing her danger), her spirits rose and she appeared in perfect health. This state of things continued until May 24th, when her father, upon returning home after an absence of several days, at once noted a very peculiar expression upon her face, different from anything he had ever observed there before.

Upon investigation he found that she had no appetite, acted depressed, and had been troubled with vomiting, complaining before and after each emesis of a peculiar itching and burning pain around the right eye. She being somewhat constipated they gave her some "salts," hoping that it was merely a "bilious attack."

The salts operated freely during the night, but she appearing no better, they started next morning, May 25th, for this post dreading lest their worst fears were about to be realized.

Upon examination I found the child lying quietly in bed, pulse rather hard and full, skin dry, tongue coated with whitish yellow fur, and a slight stare to the eyes.

She complained of nothing whatever, said she had no pain at present about the eye or head, acted as though she did not care to be disturbed, and was perfectly rational.

Ordered some small pieces of ice to allay any vomiting.

Visited her again at 9 A.M.; found the ice had relieved the vomiting. Prevailing upon her to sit up in a chair, she drooped her head upon her hands, and persistently kept her gaze fixed upon the floor. Said she wanted nothing to eat, although she had then eaten nothing for over forty-eight hours. When offered food she refused, and turned away her head to avoid seeing it. The mother, by my direction, brought some water in a basin to bathe her face and hands. Having stepped out of the room for a moment, I was called, and told that the child complained of pain every time they attempted to touch her with a wet cloth. I told the mother to try again; she did so, but no sooner did the water touch her face than she had a very well-marked, but not severe, convulsion, clutching at her throat and face.

The convulsion was preceded and accompanied by marked redness about the region of the bite, radiating

over the forehead and down upon the cheek. Convulsions were of the clonic type, laryngeal spasm very pronounced.

Attempted to administer ether, but it only made matters worse. Then gave her $\frac{1}{2}$ grain alcoholic ext. Calabar bean hypodermically. The child being unfavorably situated, owing to the house being quite small and the occupants numerous, I ordered her to be taken to the hospital, where a room was assigned to her, and Steward C. W. Croft gave her the closest attention in seeing the treatment carried out, keeping careful notes of treatment and progress of disease, and seeing that everything was done that could be for her comfort.

11 A.M.—Ordered ξ ij. beef-tea per rectum, which was retained nicely. At 12.30 P.M. took small piece of ice on handkerchief with some trouble. Food being offered upon a spoon, for which she expressed desire, she was again seized with convulsions of short duration. Saw her again at 1 P.M.; had several spasms of milder type.

Administered $\frac{1}{2}$ gr. Calabar bean hypodermically.

Pulse 100; temperature $99\frac{3}{10}^{\circ}$ F.

3 P.M.— ξ ij. beef-tea per rectum, but was rejected.

5 P.M.— ξ ij. beef-tea injected and retained.

6 P.M.—Small piece of ice again offered, which brought on spasm, but was finally taken and swallowed with great difficulty.

7.30 P.M.— $\frac{1}{2}$ gr. Calabar bean injected hypodermically.

During the afternoon the patient was more or less delirious. Any one coming into the room excited and threw her into spasms. It worried her to be looked at, and she would shift her position and try to avoid their gaze. She suffered greatly but heroically during the day, but towards evening the agony became so great that she gave frequent expressions to her suffering.

The vomiting, which was allayed for a short time during the morning, again set in and continued until death brought relief. Between the spasms of pain and vomiting she was bathed in a profuse perspiration.

At 8 P.M.—Beef-tea again injected, but immediately thrown off.

8.30 P.M.—Pulse 118; temperature 101° F.

10 P.M.— ξ ij. milk injected per rectum, which produced convulsions of severe type. The last few injections were attended with great difficulty, and were here abandoned, as they only appeared to increase the suffering.

At 1 A.M. $\frac{1}{2}$ gr. morphia sulph., hypodermically, the administration of which brought on the convulsions anew, which assumed at this time a very serious and alarming character, continuing with hardly an intermission for about two hours, requiring at times main force to keep her in the bed. From this time on everything tended to increase her sufferings, a draught of air, opening of a door, touch, look, sight of any glass-ware, all reproduced the seizures.

The countenance expressed great anxiety, excitement, and terror. Had tried several times since the morning to administer ether or chloroform, but every attempt was baffled by such alarming convulsions and laryngeal spasm that it had to be abandoned.

About 3 A.M. the patient became exhausted, with a scarcely perceptible pulse; the convulsions were less in number, but more severe in character. Could not take the temperature, as the thermometer was liable to be broken in the attempt.

At 5 A.M. gave hypodermically $\frac{1}{2}$ gr. morphia sulph., which gave her some slight relief, and she rallied slightly, but only for a short time. She grew rapidly worse, and suffered so much that at 7.30 A.M.

gave another $\frac{1}{2}$ gr. morphia sulph., but with no apparent effect. Nature was being exhausted, and unable to throw off the accumulations of viscid mucus; and when I again saw her a few moments after injection, she was apparently dying from asphyxia, being at the time under the influence of a terrible convulsion. She was pulseless. Respirations labored—four or five per minute; lips and face of a purplish hue. Administered chloroform, the spasm relaxed, pulse reappeared, color returned to face, respirations became easier and more frequent. This condition of improvement lasted probably one-half hour, at which time another and still more severe convulsion seized her, which chloroform possessed no power to alleviate, and lasted until death closed the scene, and her sufferings were ended.

The characteristic frothy mucus was present from the first, and was expelled in great quantities. Horror of water was typical, even ice produced the same effect; solid food, medicine, everything offered her was productive of the same result. Was not able to give her anything by the mouth, excepting the few pieces of ice already mentioned.

This case is of interest, as showing, in so far as one case can, that the assertion advanced by Dr. J. Janeway, U. S. Army, may be incorrect, viz.: "It is a well authenticated fact that rabid skunks are entirely free from the odor so characteristic of these animals, which could not occur if the secretion was not exhausted, and, forgetting its normal timidity, will attack any person or animal he may come in contact with, etc."

In my case the connections of the patient hoped everything from this theory of the skunk *not* being rabid, as it gave off the peculiar odor; and I have found so far that it is a popular belief among pioneers and hunters that none but odorless skunks are dangerous. I must side with Dr. Janeway, that "mephitic inoculation is not necessarily fatal."

I was visited May 26th by —, woodchopper by occupation, who was suffering from acute diarrhoea. During the interview he spoke of some very queer sensations he had been having, principally about the head; but also affecting his whole body more or less.

I asked him if he had received any injury about the head; said not; and the only injury he had had for some time that amounted to anything, was the bite of a skunk some three years before—at the same time showing me a scar upon the forefinger of the right hand; the cicatrix was very well marked, and of a purplish hue. He said it did not worry him any, although it might possibly have something to do with the way he felt; but thought it amounted to nothing, as the animal when killed gave out the peculiar odor.

Mr. W—, father of my patient, who is a very intelligent man, told me of two cases that had been bitten at his ranch during the last year, and neither having any symptoms.

Also of a third who was bitten near his place since his own child was bitten, and who, he thought, was either going to be affected, or else was in great fear of it, judging from the way he acted.

I know also of a well-authenticated case, when, during a scout (year 1877), one colored soldier and two Indians were bitten by one skunk, neither of the three showing any symptom of rabies, so far as is known. The soldier, who was the first attacked, was bitten through the upper lip, and had to choke the animal to make it loosen its hold; he afterward kicked, clubbed, and finally killed it, not the least odor being given off, but the "timid animal" showing fight to the last.

This man is still in the service, and I know has

never had a symptom. In his case poultices of tobacco and whiskey were applied to wound. It may have been the applications that exempted him, or perhaps by going a little farther we might conclude that the negro is impervious to this poison.

I think, after reading Dr. Janeway's cases and looking back upon my own, that it is simply "hydrophobia" as laid down by authors on the latter malady.

FORT ELLIOT, TEXAS.

Reports of Hospitals.

THE CHILDREN'S HOSPITAL, PHILADELPHIA.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

(Prepared for THE MEDICAL RECORD.)

THE HYPERDISTENTION OF ABSCESSSES.

This treatment of abscesses, first tried by Mr. Callender, of London, has been tried with excellent effects at this hospital. The cases were both of them in the service of Dr. H. Lenox Hodge. In the first, that of a large femoral abscess in a child suffering with coxalgia, the abscess was first opened with a bistoury, and a large amount of pus discharged by gentle pressure. A five per cent. solution of carbolic acid in water was then injected through a common syringe, with tube attached, so as to completely fill up the abscess to overflowing. This hyperdistention caused a number of cheesy, shreddy, and fibrous particles to be discharged. No constitutional symptoms followed, and no pus to speak of came out on the carbolized oil-dressing afterward. The injection was repeated thirteen days afterward. At no time after the first injection were more than a few drops of pus exuded.

In the second case the results, though fair, were not so immediate and pronounced as in the first case; the temperature showing a constant tendency to rise and the pus still continuing to be discharged.

SERIOUS BURN FOLLOWED BY CONTRACTION OF TISSUE—CURED BY NITRATE OF SILVER AND PRESSURE CAREFULLY APPLIED BY MEANS OF ROLLERS.

J. T. F., æt. 10, admitted to the hospital on January 14, 1879. This boy was badly burned, both above and below the elbow, and completely around the arm. Before coming to the hospital he had been treated for some six months at his home.

When first seen by the resident surgeon, Dr. J. M. Taylor, the burn was seen to have penetrated the muscles and showed pouting granulations of from two to three inches in diameter encircling the arm. The elbow was much contracted.

When Dr. John Ashhurst first saw the case he thought that amputation would have to be performed. A dressing of oxide of zinc was immediately applied, the discharge of pus at that time being considerable. On the 20th of January, six days after admission, the granulations had very largely diminished under the use of the nitrate of silver, and in some places above the elbow the skin had united, forming narrow patches of healthy epidermis. On January 28th the granulations were all healing rapidly. On February 16th the arm was entirely cured.

The resident surgeon, Dr. Taylor, took great interest in the case, and each day straightened the arm

out carefully as far as it would go, seeking to make it straighter at each visit. The nitrate of silver was applied with great thoroughness and care, and after each application the arm was bound up pretty tightly with turns of the roller over an oakum pad.

RAPID RECOVERY FROM DEPRESSED FRACTURE OF THE FRONTAL BONE.

The following case occurred in the service of Dr. H. Lenox Hodge: T. C., æt. 4, while playing on tow-path of a canal, was caught under his chin by the tow-line, and thrown violently down a bank estimated to be about twelve feet high. His head came in contact with a piece of cinder. This accident occurred at 6 P.M. on June 24th. The child was in the hospital by 8 P.M. Upon examination, a depressed fracture of the frontal bone about three-quarters of an inch above the superciliary ridge upon the outer edge of the frontal eminence was found. The wound extended for some seven lines, and was accompanied by much laceration of the soft parts. The pupils were widely dilated. The breathing was stertorous, and the condition that of general hebetude. The boy was not rendered insensible by the fall, but soon afterward lapsed into a comatose condition, only arousing himself to ask for water.

The treatment consisted in the coaptation of the sides of the wound with adhesive strips, and in placing over this a dressing of simple cerate. An ice-bag was applied to the head and a simple fever mixture given internally. The temperature immediately upon admission was 99° F. The next morning the boy was bright and cheerful; complained of no pain and asked for food. His pupils were contracted. As a precaution a catheter was passed, but its use was not again required.

June 26th.—Bowels not yet opened. A dose of castor-oil given.

June 27th.—Bowels still inactive, but boy very bright and enters readily into conversation on any topic.

June 28th.—Bowels and bladder both acting regularly. Wound healing. Boy takes nap or two during day and sleeps regularly at night. Patient left hospital soon afterward entirely well.

SCARLET FEVER FOLLOWED BY LOSS OF CO-ORDINATED MOVEMENT AND BY INFANTILE PARALYSIS—RED-SORES, ETC.

R. C., æt. 7, admitted August 24, 1878. Never had chorea or any other nervous trouble. Was always healthy and strong until he was about eighteen months of age, when he was attacked with scarlet fever. While convalescing from this disease he caught a cold, which was followed by "sore mouth," etc. At that time also he began to lose power of co-ordination of motion and had to be retaught to walk.

In September, 1877, the paralysis began. There were also at that time severe pains in the abdomen, causing the child to scream repeatedly. These pains continued, and attacked the back of the child's neck and head. Ever since then the child has suffered considerably from headache. On the second day after the first symptoms of loss of co-ordination were manifested there was marked retention of urine. The boy was catheterized and has been incontinent of his urine ever since; the urine constantly dribbling away, much to the patient's annoyance. Phimosi exhibited itself shortly after this; the boy was circumcised on September 3, 1878.

Prior to admission the boy had been treated by blisters to the spine and by electricity. During the

*early part of 1878 there was paralysis of both motion and sensation in the extremities. Since admission the patient was treated with iron, quinia, and ergot. Manipulation of the paralyzed parts was also daily practised. This treatment was followed at once by marked improvement. In October of the same year the patient, while under Dr. Pepper's care, had an attack of bronchitis, which was treated by carbonate of ammonium, cod-liver oil by inunction, quinia, and milk-punch. Though recovering from this attack the patient's general health began to fail and his condition became complicated by numerous bed-sores. These increased to such an alarming extent that at the time of writing the head of the boy's left femur is exposed, and almost the whole length of the spine is bare of skin. The treatment at present is only directed towards maintaining life as long as possible.

TRIANGULAR DECUBITUS AS A RESULT OF TUBERCULAR MENINGITIS.

The patient, when admitted on the 20th of January, 1879, was extremely reduced in strength, and his head presented an enlarged, hydrocephalic appearance. His eyes were fixed and staring. His ears, nose, and the sinuses in his neck were discharging a thick, serofulons pus. His body was much emaciated, and his extremities were constantly in a state of trembling. The decubitus was triangular and very characteristic. Treatment was of no avail. February 4, 1879, the patient was found in his foot-and-head position dead.

Progress of Medical Science.

THE THERAPEUTIC ADMINISTRATION OF LIME-SALTS.—There has been discord between chemists and physicians on the subject of the administration of lime-salts: the chemists denying the possibility of any general action on the system, and practitioners claiming that this action is sufficiently demonstrated by the valuable effects of the prolonged employment of phosphate of lime, or of calcic mineral waters. Perl has endeavored to solve the problem by experiments, which he details in the German *Archives of Pathological Anatomy*. He administered to a female dog a fixed quantity of very dilute chloride of calcium, and minutely analyzed the urine and feces. Without entering into the detail of these difficult experiments, it may be enough to say that the salt administered was decomposed in such fashion that the chlorine appeared in the urine and the lime in the feces. Under the conditions of the experiment, there was a very slight absorption of the lime-salt, which, if accepted, puts an end to the discussion and answers the chemical objections, while it justifies the employment of a method of treatment which, from time immemorial, has been employed by practitioners in rickets and tuberculosis.—*The Practitioner*, July.

EXTIRPATION OF A RETRO-PHARYNGEAL GOITRE.—M. Boeckel, of Strasburg, reports the case of a woman, aged 25 years, who applied to him in November, 1878, for the relief of a voluminous tumor in the right side of the neck, and of a second tumor situated behind the pharynx. The first tumor made its appearance in 1875, but only commenced to grow rapidly in the early part of 1878. The respiration was not impeded. The skin of the neck was tensely stretched, but was of a normal color. The larynx was crowded to the left.

There was neither pain nor fever, but the movements of the head were impeded. A cyst of the thyroid gland was diagnosed and evacuated, but the retro-pharyngeal tumor was not affected by the operation. As the cyst soon filled again, a radical operation was performed in December. An incision, four and a half inches long, was made along the anterior border of the sterno-mastoid muscle under the carbolic spray, and the cyst was punctured with a bistoury, drawn out and removed. Ten ligatures were required to control the hemorrhage. The retro-pharyngeal tumor was removed with the large cyst, and was found to be a cyst connected, but not communicating, with the larger cyst. M. Recklinghausen, who examined the cysts, believed that they were formed at the expense of the thyroid tissue. In January the wound had closed completely, and the patient was discharged cured.—*La France Médicale*, April 12th.

IMPROVEMENT OF AN OLD OPACITY OF THE CORNEA UNDER THE INFLUENCE OF A GONORRHOICAL OPHTHALMIA.—Dr. Chevallereau reports the following case: A man, who presented a large opacity on the right cornea, dating from his childhood, was subject to attacks of subacute blepharitis, which, in accordance with a popular prejudice, he treated by bathing the eye in his own urine. The last time he had occasion to use this treatment he happened to be suffering from gonorrhoea, and the result was a violent attack of gonorrhoeal ophthalmia. This dangerous complication yielded to an energetic treatment, and the patient then found that he could see better than before. Examination showed that the opacity has diminished very markedly, both in size and in density.—*Annales de Dermat. et Syph.*, vol. x., No. 3.

THE ACTION OF SCLEROTINIC ACID ON MEN.—The investigations of Nikitin seemed to demonstrate that sclerotinic acid could be substituted with advantage for ergot, in all cases in which the latter is now employed, but the following *résumé* of the results obtained by Dr. Kobert, of Halle, from an extensive trial of the acid, show that its supposed advantages are, to say the least, exceedingly problematical:

1. In severe pulmonary hemorrhages the remedy, given in doses of three grains five times a day, proved absolutely inert. In the case of a patient who expectedorated daily for two months a small quantity of blood, the effect of the acid was exceedingly doubtful, and by no means so marked as that of ergot. Subcutaneous injections of a grain and a half, both of the free and of the neutralized acid, caused intense pain, and violent inflammation of the skin requiring the constant local use of ice for several days.

2. In a case of chronic multiple hemorrhages into the skin and the mucous membranes, the acid, in doses of fifteen grains *pro die*, proved entirely useless.

3. In two cases of disease of the spinal cord, with spastic manifestations in the lower limbs, the acid was administered for weeks without the slightest improvement in any of the symptoms. At the most, the urine was increased slightly in quantity.

4. In a case of Basedow's disease, the first powder (three grains) caused such restlessness and cardiac anxiety, that the remedy had to be discontinued at once.

5. In the cases of two tabetic patients, as well as of several other persons, to whom the drug was administered for the sake of studying its action on the subjective condition and on the central nervous system, it was given for several weeks without the slightest effect. No person could be persuaded to submit to a continued subcutaneous administration of the drug.

6. A woman, who took the acid continuously for over three weeks, complained on the first day of the fourth week of formication in both great toes, and on the following day in both little fingers also, which rapidly increased to complete numbness of the affected parts. When the drug was discontinued the symptoms disappeared, but they reappeared as soon as the former doses were resumed; smaller doses, however, were borne without difficulty.

To exclude the possibility of failure from impurities in the acid, a fresh preparation was made in Halle, with all possible care. On animals this fresh preparation produced the effects described by Nikitin, but on men it proved as inert as the ordinary drug. In no case did it produce contractions of the intestines, abdominal pains, or diarrhoea; an action on the uterus seemed also wanting.—*Centralblatt für Gynäk.*, May 10th.

NITRITE OF AMYL IN CHLORAL POISONING.—The antagonism between nitrite of amyl and chloral hydrate is well illustrated in the following case of chloral poisoning, related by Dr. Coghill in the *British Medical Journal*, June 28th. A gentleman, aged sixty-two, late in the evening of April 23d, took a large, but unfortunately unascertained dose of his favorite anodyne, chloral. Within a few minutes he became completely insensible. When Dr. Coghill saw him, two hours later, artificial respiration had been kept up for some time, with the effect of inducing feeble, gasping respiration, at the rate of four per minute; surface was cold and deeply cyanosed; pupils strongly contracted; pulse eighty, full, but soft and compressible. Twenty drops of nitrite of amyl were administered by inhalation, which induced an immediate return of warmth and natural color to the surface, even of the extremities. The respirations became deeper, and gradually increased in frequency. The amyl was repeated in a smaller dose in about two hours, with permanent effect. The next morning the general condition had improved, but consciousness had not returned. It was found impossible to administer nourishment by the mouth, and nutritive and stimulant enema were consequently resorted to. After the second enema he became sensible, recognized and spoke to those around him, and swallowed some food with little trouble. He continued to improve until 9 p. m., when he suddenly started up, as if from sleep, and fell back dead.

Dr. Coghill accepts Liebreich's theory of the decomposition of chloral in the system into chloroform and formic acid, attributing its effects to the chloroform. The state of the pupils, he thinks, depends upon the manner of administration: as with chloroform, when an overdose is taken, the respiratory centres are paralyzed, the pupils *contracted*, but the pulse not affected; but when the poisoning is due to too frequent repetition of smaller doses, the cumulative action of the drug is manifested, and we find the heart yielding earlier than the respiration, and the pupils *dilated*. He suggests that nitrite of amyl will be the appropriate remedy, when the drug has been administered in such quantities as to act rapidly on the respiratory centres, *with contracted pupils*, and that strychnia should be given when the drug has acted slowly as a cumulative poison, when the heart has succumbed, *and the pupils are found dilated*.

FARADISM AND SUSPENDED ANIMATION.—Dr. Altman recommends the faradic current as a test for suspended animation. Three hours after death, every trace of farado-muscular irritability is found to have disappeared, and the most powerful current will re-

main absolutely ineffectual; while in suspended animation the muscles respond freely to a current of moderate force.—*The British Medical Journal*, June 28, 1829.

BEEF AND ICE CREAM.—Dr. Tucker recommends a combination of beef and ice cream as an article of diet for invalids. He uses cream, 120 grms.; sugar, 30 grms.; ext. vanilla, 8 grms.; beef-juice, 8 grms. Johnston's beef-juice was generally used, but that squeezed from a beefsteak will answer. Any confectioner can make it, or it can be prepared at home.—*The Chicago Medical Journal and Examiner*, July, 1879.

ETIOLOGY OF ALOPECIA AREATA.—Dr. Hans Büchner contributes his share to this vexed question. His conclusions are as follows:—1. The hypothesis that the loss of hair in alopecia areata is due to faulty innervation of the trophic nerves, is untenable on anatomical and physiological grounds. 2. The theory which attributes the disease to diminished nutrition with lessened growth of the hair is no explanation, but only a description of the affection. 3. The fungus theory is the only one which is justifiable in the present condition of our knowledge. The lack of microscopic proof of the presence of fungi up to the present time does not invalidate this hypothesis, because, under present circumstances, small single-celled non-colonized schizomyces may escape observation. Certainty in this question can only be attained by careful researches in cultivation together with inoculations.—*Philadelphia Medical Times*, July 19, 1879.

QUININE IN GOUT.—Dr. Schoenemann has used quinine to cut short the paroxysms of gout, over which disease it has, in his estimation, as much power as over intermittent fever. From among the half-dozen cases he has treated with this drug he gives the notes of one, a typical case. For two days and nights the patient had suffered so intensely as to be deprived of all sleep. On the third evening Dr. Schoenemann was called in, and endeavored ineffectually to relieve pain and induce sleep by fifteen-minim doses of tinct. opii every half-hour. The next day the joint was painted with tr. iodi., and quinae sulph., grs. xv., with sodæ bicarbonat. ʒij. given in divided doses during the day. Patient slept all night, having only occasional and light darting pains; in the morning he got up, put on his boots and attended to work without suffering any inconvenience.—*Pacific Medical and Surgical Journal*, July, 1879.

EARLY SYPHILITIC AFFECTIONS OF THE NERVOUS CENTRES.—Prof. Mauriac closes a long and able paper on this subject, with the following deductions from the facts and researches at his command:

1. Syphilis may attack the nervous centres at a very early period after the initial lesion.
2. The early cerebro-spinal lesions are those which develop during the virulent period of the malady, that is to say, during the first two or three years.
3. There are degrees in this precocity of the cerebro-spinal syphiloses: the first include those which set in within the first twelve months; the second those which develop in the second or third year of the constitutional malady. Statistics seem to show that those of the first degree are more common than those of the second.
4. Among the early visceral localizations of syphilis, those in the cerebro-spinal system are incomparably the most numerous.
5. They are also the most dangerous. Their gravity does not increase with their diathetic age; those which

develop during the first months of syphilis are as formidable as those which belong to the more advanced stages of the malady.

6. All the forms, all the degrees, all the phenomenal combinations that constitute the symptomatology and the processus of the localizations of syphilis in the neural system, are met with in the early as well as in the late cerebro spinal syphiloses.

7. Certain symptomatic complexes, however, seem to predominate. The most frequent are those which consist in an attack of hemiplegia, involving the whole of one side of the body.

8. Among the attacks of hemiplegia, the syndroma comprising right hemiplegia and aphasia is the most common.

9. The paralytic forms are much more common than the convulsive or epileptic, in the early cerebral syphiloses.

10. In the cerebro-spinal syphiloses the psychical troubles and the inco-ordination of movements are never systematized as they are in mania, general paralysis, and locomotor ataxia.

11. The absence of systematization in the cerebro-spinal syphiloses must be regarded as one of their chief characteristics. The only exception is in the case of the syndroma of right hemiplegia and aphasia.

12. Early localizations of syphilis in the spinal cord are much less common than in the encephalon.

13. The lesions which seem to belong to the early cerebro spinal syphiloses are diffuse or, more frequently, circumscribed hyperplastic effusions into the cortical layer of the brain and the pia mater, and changes in the Sylvian arteries with consecutive ischaemic softening.

14. In some cases of early cerebro-spinal syphiloses that terminated fatally, no lesion was found, but at that time the existence of arterial syphilis had not been recognized. It may be presumed that death had resulted from sudden anemia of the nervous centres that are essential to life.

15. With regard to the etiology of the early cerebro-spinal syphiloses, only very vague conjectures can be advanced. In most of the cases, the initial lesion as well as the consecutive cutaneous and mucous manifestations were very mild in character.

16. The general cause of the constitutional malady is not modified by the appearance of early localizations in the nervous centres. The other manifestations develop before, during, and after the localization in the neural system, without presenting any deviations from their usual forms, degrees, course, or topography.

17. The precocity of the cerebro-spinal syphiloses furnishes no special indication with regard to treatment. Whatever may be the age of the constitutional malady, the localizations in the nervous centres demand the same specific medication. The peculiar conditions of each case furnish the secondary indications relative to the choice, doses, and combinations of the two specific agents.—*Annales de Dermatol. et de Syphilig.*, Vol. X., No. 3.

ON THE TREATMENT OF CHOREA.—Dr. Hayden believes the attack is in most cases directly traceable to fright or other emotional excitement of a depressing character, operating upon a feeble and nervous constitution, at a period of life when the receptive faculties are most sensitive. He therefore concludes that phosphorus and strychnia combined—the former a nerve nutrient of recognized value, and the latter a nerve tonic of great potency—may prove efficacious in the treatment of chorea. As yet his experience of this plan of treatment has been very limited, extending

only to three cases, but so far it has been eminently satisfactory. The strychnia and phosphorus were administered in 3 ℥. doses of the liquor and ethereal tincture, thrice a day, so that the total amount of each drug given was 9 ℥. The patients were children of nine to eleven years of age.—*The Practitioner*, July, 1879.

THE THERAPEUTIC VALUE OF HYDROCYANIC ACID.—Dr. Macdonald calls attention to the value of hydrocyanic acid in arresting the night cough of children. In a case of sixteen months' standing, where the bromides and change of air had been prescribed in vain, relief was afforded in forty-eight hours by the administration of the acid. The good effects of the remedy were especially apparent in the night attacks. It was particularly noticed that, when a paroxysm came on, it ceased suddenly and unexpectedly five minutes after each dose. Within a week a cure had been effected, and the patient is now in the full enjoyment of robust health.—*The Practitioner*, July, 1879.

PREPARATION OF IMITATION KUMYSS.—Fill into a strong champagne bottle good, fresh unboiled cow's milk to such a height, that after the addition of 30 grammes (1 oz.) of sugar, there may still be at least an inch of empty space below the cork. Before corking, add a piece of fresh compressed yeast, or a teaspoonful of good beer yeast. The contents of the bottle must be well shaken repeatedly, and then placed in the cellar, where they are to be turned up and down a few times during the day. The mixture is ready on the fifth day, and may be drunk to about the twentieth. It is best to prepare about six bottles at a time, refilling each after being emptied, so that the treatment once commenced may not be interrupted. Care should be observed in opening the bottles, as the contents are apt to foam over. A good milk-wine, or kumyss, should have a homogeneous appearance and the consistency of thin cream, should effervesce when poured out, and be of an acidulous, agreeably vinous odor and taste; it should not be full of lumps, or taste like buttermilk. At first it produces looseness of the bowels, but this effect soon passes off.—*New Remedies*.

SYPHILITIC POTT'S DISEASE.—M. Verneuil showed at his clinic a child suffering from caries of the spine, which he considered to be of syphilitic origin. The previous history of the case was imperfect, but the evidences of the constitutional taint were convincing. Attention was called to the rarity of, and difficulty of diagnosing this affection, and mention was made of a similar case occurring in the same service. In the last case the happy influence of specific treatment confirmed the diagnosis. Preparations were also shown which demonstrated the gummy infiltration into the vertebral substance. The diagnosis in these cases is always uncertain; some peculiarity in old cicatrices, or in the openings of fistule, or the condition of the glands, is sufficient to call attention to the possibility of the syphilitic diathesis, and is the indication for treatment.—*Annales de Dermatologie*.

CHICAGO MEDICAL JOURNAL AND EXAMINER.—Drs. F. C. Hotz and E. F. Ingals have retired from the editorial staff of the above journal. Their places are filled by Dr. N. S. Davis, Dean of the Faculty of the Chicago Medical College, and by Dr. D. R. Brower, one of the Faculty of the Woman's Hospital Medical College of Chicago.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, August 16, 1879.

LITHOTRITY WITH EVACUATION OF THE FRAGMENTS.

I. THE DEVELOPMENT AND PRINCIPLES OF THE OPERATION.

THE recent modification in the method of treating stone in the bladder by lithotripsy, with which the name of Professor Bigelow is so prominently associated, bids fair to make lithotomy a rare operation by notably restricting its field of application, and to diminish the proportion of cases in which patients return with a second stone developed about an unremoved fragment of the first. The great objection to lithotripsy as heretofore practised—that is, by repeated crushings of short duration, at intervals of a few days, with unaided escape of the fragments through the urethra—lay in the fact that the large sharp fragments retained in the bladder sometimes tore and bruised it to an extent which not only aggravated the pain and distress of the accompanying cystitis, but actually imperilled the life of the patient. Lithotomy, while free from this objection, involved the risks incident to an extensive incision through important parts. The new method of lithotripsy happily avoids the risks of the old method and of lithotomy, by removing the stone at a single sitting without the aid of the knife. Its field, therefore, embraces all the cases which could be properly treated by the old method, and in addition many of those which it was formerly considered safer to treat by lithotomy. It seems probable that the latter operation must now be restricted to cases presenting some important urethral or prostatic complication, and to the removal of very large hard stones and of stones in infants and youths whose urethras are too small or too sensitive to allow of prolonged instrumentation. Fortunately, this latter class is the largest of the three, is the one in which the risks of lithotomy are lowest, and is that in which the rate of mortality is very small. As the supra-

pubic operation has been considered the safest for exceptionally large stones, the rule of treatment, according to our present knowledge, is: perineal lithotomy for the young and some specially complicated cases; supra-pubic lithotomy for exceptionally large hard stones; rapid lithotripsy, with evacuation, for all others. The outcome of Prof. Bigelow's modification then, is to enlarge the field and diminish the risks of lithotripsy. Let us see in what the modification consists, and how it has been brought about.

The rule of practice in lithotomy was to retain the lithotrite in the bladder for not more than two or three minutes, during which time the stone was to be caught and crushed as frequently as possible. Then, after an interval of a few days, during which the patient passed unaided, and with more or less pain and anxiety, such fragments as might be carried through his urethra by the stream of urine, another short crushing, and so on until all was removed. The first formal step in the road which has led to the present mode of operation was made about fifteen years ago by Mr. Clover, and was an attempt to remove the fragments through a catheter immediately after each crushing. He devised a rubber ball and glass attachment to be filled with water and fitted over the end of the catheter in such manner that by alternately compressing and relaxing its sides, the water could be forced into the bladder and sucked out again, bringing with it the fragments. The idea—an old one, moreover—was essentially the same as that of the washing-bottles now in use, but the instrument was inferior to them in not properly preventing the return of fragments into the bladder after they had been once drawn out. The catheter entered at the most dependent portion of the bulb, and although its end projected one or two inches into the bulb, the adjoining portion of the latter was so narrow, and the currents so vigorous, that this was an insufficient protection. Nélaton substituted a metallic pump for the rubber bulb, increasing the already too great suction of Clover's stiff ball, and Tillaux hung a perforated valve over the end of the catheter to remedy a minor defect, but the instrument remained generally ignored and unsatisfactory, not simply because it did not properly do the work expected of it, but because that work was relatively insignificant and unimportant. It was practically valueless because it was not associated with immediate and complete fragmentation of the stone. Moreover, it contained no new and important principle, and was a commonplace adaptation of common mechanical means to obtain a result which could be, and was, equally well obtained by the use of a catheter and syringe, with or without pressure upon the abdomen during the escape of the injected water.

The next modification was an attempt to shorten and dilate the route to the bladder, and remove the stone at a single sitting by the use of powerful litho-

clasts. This modification was Dolbeau's *perineal lithotripsy*. He cut through the perineum to the membranous urethra, dilated the prostatic portion of that canal, crushed the stone, and washed out the fragments. This met the indication of removing the stone at a single sitting, but it involved an incision and violence to the neck of the bladder, which were only somewhat less severe than those incidental to lithotomy. It was, in fact, a modification rather of lithotomy than of lithotripsy, and, notwithstanding its ardent support by Dolbeau, it was received but coldly.

The final step was taken by Prof. Bigelow, and it is interesting to note how in this case, as in so many others, men have played about a great fact until at last one of them fairly stumbles upon it in his search for something else. In using this expression we do not mean to detract in any manner from the credit which belongs to Prof. Bigelow. He saw the fact, recognized it, and promptly made use of it. The fact was the tolerance of the bladder to the use of instruments within it. This tolerance, the fact that a lithotrite can be worked for an hour or two in the bladder without inflicting serious injury upon it, is the centre upon which the new method rests; and beside it, all modifications in the jaws and handles of lithotrites, and in the shape of washing-bottles, are matters of minor importance. That this tolerance should have remained so long ignored is to be explained only by the benumbing effects of authority and tradition. The teachers said: "Never retain a lithotrite more than three minutes in the bladder," and that dictum ruled lithotripsy so nearly to its ruin that Sir Henry Thompson, less than eighteen months ago, declared in the discussion in the Royal Medico-Chirurgical Society, following his report of 500 cases of stone, that it should be restricted to the treatment of such stones as could be removed in two or three crushings; and Sir James Paget, in the same discussion, said the rule should be lithotomy, lithotripsy the exception.

Many lithotritists went beyond the three-minute rule, but they did it only occasionally and, as it were, under protest; lithotomists spent half an hour sometimes in the search for fragments; perineal lithotritists spent even more in crushing and washing; general surgeons tied catheters into the bladder, and all physicians were familiar with the fact that a stone might lie in the bladder for months without giving rise to cystitis, and yet no one, until Prof. Bigelow, drew what seems now such a palpable inference. Sir Henry Thompson claims that he did so; but, so far as we can judge, he did no more than many others; that is, he departed, in exceptional cases, from the rule of short sittings, and was perhaps drifting slowly, as were also others, toward more prolonged crushings under ether; but it was only a drift, and was very different from Prof. Bigelow's sudden recognition of a principle of general application.

Prof. Bigelow, feeling the necessity for removing

the fragments after a crushing, set himself to improving the washing apparatus, and did it in the very efficient manner to be hereafter described. In his first case there were three sittings at intervals of seven and twelve days. At the first sitting he crushed and did not wash; at the second he crushed under ether and washed, removing "a large mass of fragments;" at the third he crushed again, apparently, and washed, removing "a few fragments." Up to this moment he had done only what he and others had done before in exceptional cases, he had largely overstepped the rule of short sittings, and, in addition, he had washed with an effective apparatus. But in doing this he had encountered and recognized the fact of the bladder's tolerance, and he profited by it to remove the stone in his next case, five months afterward, at a single sitting. He had then enunciated the principle; he had put lithotripsy upon a new basis; he had *fait école*.

It is singular, in view of the paramount importance of this principle, to see Prof. Bigelow insist so strongly upon the merits of certain of his instrumental details and modifications, an insistence which only draws attention away from the principal and most meritorious point. What earthly difference can it make to him whether it is generally considered easier to lock the lithotrite by a turn of the wrist or by a movement of the thumb, when both are so easy? or whether others use a male jaw with lateral grooves, or a female jaw with a large fenestra, provided neither becomes impacted? These are matters of individual appreciation or preference which he can certainly afford to disregard.

In like manner, the attempt to give the operation a new name conveys a doubt of its ability to force recognition of what is original in it, and implies a failure to appreciate its real position. The right of the *method*, which includes all the various *procedures* for crushing a stone, to the name lithotripsy is established by the baptism of its originator and the acceptance of all surgeons, and this latest modification, which departs in no manner from its central idea, but only perfects its processes and enlarges its field of usefulness, is the natural heir to the title and to the honors of its predecessor. There can be no question but that in due time when "lithotripsy" is spoken of, the removal of a stone at a single sitting will be meant, and Prof. Bigelow's connection with it does not need to be fortified by the substitution of a new name for the old one. Indeed, the new name seems to have been an afterthought, inspired five months after the publication of Prof. Bigelow's article by a case in which he removed a large number of small calculi without crushing them, an operation for which, if a new name is needed, *litholapaxy* (evacuation of stone) is certainly well chosen.

It is too soon to speak of the mortality of the new method except from a theoretical standpoint. Bigelow has reported only eight or ten operations; Van Buren

and Keyes twelve or thirteen. All of these, with one exception, we believe, were successful. The most that can now be said is that as the operation inflicts the minimum of violence, and, by removing the stone at once and completely, places the bladder immediately in the most favorable condition for recovery, it avoids the most important dangers of the previous methods. It will diminish the mortality in the cases heretofore treated by lithotripsy, because it will save those in which a fatal issue is the consequence of the irritation caused by the sharp fragments; and it will save many of those cases which would have died under lithotomy from loss of blood, shock, or pyemia. The theoretical reasons for believing in its value were authoritatively presented in the very able and interesting paper upon this subject which Prof. Van Buren contributed to *THE RECORD* about a year ago, and in which, referring also to the above-mentioned opinions of Sir James Paget and Sir Henry Thompson, he showed how extensively they would require to be modified in view of the advantages offered by the new method of lithotripsy.

Sir Henry Thompson's open letter to Dr. Van Buren, published in *THE RECORD*, May 24, 1879, shows how thoroughly he appreciates these advantages, and his claim to a share in the credit of the introduction of the method is a none the less sincere compliment for being, in our judgment, unallowable. The credit belongs to Prof. Bigelow and to America, and it gives us much pleasure to mention in this connection the hearty and generous reception of the new method by the lithotritists of our own city.

We propose to consider at another time the different instruments employed in the operation.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 28, 1879.

DR. JOSEPH W. HOWE, VICE-PRESIDENT, IN THE CHAIR.

RENAL CALCULI OBTAINED FROM CAMELS.

DR. LIAUTARD presented specimens of renal calculi which he had removed from the kidneys of camels.

IRREDUCIBLE DISLOCATION OF INDEX PHALANX.

DR. FRED LANGE presented a patient on whom he had performed, for an irreducible dislocation of the first phalanx of the index upon the dorsum of the metacarpus, the operation of opening the joint and lifting the interposed capsule. The smallest possible cord of the capsule, which was torn from its attachment to the metacarpus, had interposed itself like an apron between the dorsum of the metacarpus and the border of the articular plane of the phalanx, doubtless in consequence of a strong hyperextension. The boy had received a kick against the top of the index from a foot of one of his comrades. The incision of the torn part of the capsule did not allow of the re-

position of the bones. As previously, in a similar dislocation on the thumb, he was obliged to incise and draw outward the light lateral parts of the capsule, when reduction of the dislocation was effected without difficulty. A fair result was obtained. Experience had proved that the same operation to fulfil the same indication could be performed upon the largest joints if strict antiseptic treatment was used.

GUNSHOT WOUND OF THE INDEX FINGER—EXCISION OF PHALANGES.

Dr. Lange also presented a small and somewhat interesting specimen taken from a patient, who, in the end of last year, shot himself with a revolver in the region of the head of the first phalanx of the left index. He was treated in one of the New York dispensaries, and the wound healed, as he says, almost without discharge, in a fortnight. Thus the projectile was healed aseptically. The joint remained stiff, grew more painful, the bones became thickened, and the patient was obliged to give up his professional occupation as an engraver. Some months after the injury, and about two and a half months ago, when the patient applied to the German Dispensary, Dr. Lange performed excision of the joint, and in spite of the comparatively extensive and intense injury, the latter originally had not caused any suppuration. In the almost obliterated articular cavity there was only a minimum quantity of a lead-colored fluid, of about the consistency of synovia. That color pervaded at the same time the diploë of the bones, and he removed the whole of the second and a part of the first phalanx. Perhaps in consequence of too much precaution the operation grew somewhat extensive. The wound healed quickly, and after the second week the patient, by means of an articulated splint, had practised active and passive movements. The finger was considerably shortened, but it was useful and of much value to him in his professional occupation. The last phalanx had a small amount of active movability. The new formation of bone was a defective one, and he had the impression that there was somewhat like a small meniscus between the first and last phalanx. The subperiosteal excision, because of the lightness of the periosteum, was not made without trouble, all the more as he had, instead of an elevator, only the blade of a pair of scissors at his disposal. Perhaps, especially in this location, the removal of the periosteum, including the thin layer of the bony surface, after the suggestion of Prof. Voigt, would be suitable, in order to surely include the layer of bone-forming cellules, the so-called osteoblasts.

EXCISION OF THE LOWER END OF THE HUMERUS.

Dr. Lange also exhibited a patient on whom, just five months ago, he had performed excision of the lower end of the humerus for the following injury:

The boy, while standing on an elevator, had put his elbow upon the baluster. In mounting to a higher floor the elbow was squeezed between the baluster and a prominent beam. We saw the patient in consultation with Dr. Buedder about three hours later, and found the following injury: The dorsal side of the joint occupied by a large lacerated and contused wound. Skin and muscles ecchymosed to a large extent, the joint widely opened, the epiphysis humeri entirely separated from the diaphysis and was torn out from the joint, so that its articular surface looked forward. The only connection was with the internal epicondyle. The tendon of the triceps was saved, the articular parts of the forearm, though contused, were not fractured. In spite of the skin being lacerated in

the whole circumference of the joint, except a narrow bridge, no large vessels or nerves seemed to have been injured; and this induced him, confiding in antiseptics, to propose a conservative treatment, to which his colleague agreed. He removed the epiphysis and the lower prominent part of the diaphysis, which was contused, the canaliculi Haversiani being filled with extravasations. He drained the periosteal cylinder at the lowest point, made several counter-incisions at the boundaries of the loosened skin, and treated the case antiseptically as strictly as possible. Immobilization was effected by a dorsal plaster-of-Paris splint with shoulder-cap, at which a slight extension was exercised in order to prevent its slipping above and causing strangulation in the axilla by pressure of the bandages.

The discharge was very abundant; a large portion of skin, connective tissue, and of muscle sloughed, and the first ten days he was obliged to dress the limb every day. A part of the skin mummified completely upon the wound, and was lifted up after a fortnight by strong and healthy granulations. In the fourth week he made transplantations upon the extensive but now superficial wound, in order to hasten healing and thus allow orthopedic after-treatment as soon as possible. In the sixth week an immovable silicate dressing was applied, and passive movements were made methodically. Those movements were continued after the third week, at every dressing. In the third month cicatrization was perfect and some activity existed, and the result showed that the boy had regained nearly the normal use of his arm. The excision was at least 90 degrees. The articular part of the humerus had developed almost in its normal shape, and there was no preternatural mobility of the joint, of which one could be convinced by the fact that the patient was able to keep his arm elevated, at the same time flexed in the elbow-joint, while pronating the hand.

While patients with new elbow-joints could often expend some strength, keeping the elbow close to the trunk, turning the volar surface of the joint in front, and supinating the hand, they might not be able in the opposite positions even to stand the weight of the forearm; and if so, often a slight tap with the finger was sufficient to make the arm fall down with a feeling of complete weakness, probably because in that position the bones of the forearm lost their lever power which normally was secured by the ginglymoid shape of the joint, the normal bony obstructions, and the tension of the ligaments. He omitted those cases of undue mobility of the joint in which a good fulcrum did not exist in almost any position of the arm. Those cases almost never occurred if the excision was made strictly subperiosteal, but he called attention to those cases of slightly increased mobility of the joint, which give a certain amount of use and power in the new joint, and, according to his experience, occurred rather frequently in excisions for scrofulous affections of bones and joints in adults. In those cases at the same time there hardly ever existed the possibility of pro- and supination in the regular form. Still those patients made pro- and supination, but by displacing both bones, radius and ulna, from the articular part of the humerus. In the case presented there existed some motion of the head of the radius in the ulno-radial joint, which probably would be more extensive if the head was not fixed by the tightly adherent cicatrix.

The experience gave the practical indication to keep the new bones in a certain amount of contact from a certain stage of their development, in order to

secure as large a joint surface as possible, as short ligaments as possible, and that in as early a stage as possible, especially in those cases in which an extensive formation of new bone was not expected.

The apparatus worn was regarded as of some usefulness, because it perfectly fulfilled one indication of great importance in the after-treatment of elbow resections, by taking off from the joint the weight of the forearm, and by keeping the forearm, as a rule, in a bent position. He considered that point as an important one, because only in that position the articular surface of the ulna faced the cross end of the humerus. From that position he had made a kind of passive extension by causing the patient to lift such heavy weights that the power of the rubber strips, and of the muscular resistance was overcome to a slight degree. The flexion to an acute angle was left to be brought about by muscular activity. An articulated silicate dress, ending at the upper arm, has newly been recommended by Dr. Genzmer, in Halle. Those lower rubber strips he tried first, when assistant of Prof. Esmarch, by his recommendation, in combination with the well-known apparatus of Bidder. They were, however, not so strong that the arm was kept in a right angular position, and they had only to support the muscular power of that patient, who, in consequence of constriction for bloodless operation, had got a perfect and very obstinate paralysis of the plexus brachialis. The only case of such an accident he saw in Kiel.

Furthermore, he emphasized that the shell for the upper arm ought not to be applied tightly. The upper strips prevent it very well from slipping down, and mediate very sure the transposition of the weight of the forearm to the shoulder. If we would dispense with the shoulder part and transfer the weight to the upper arm only, the shell would have to be applied tightly, and this easily gives rise to troubles of the circulation, especially in the beginning, at which time the circulation was still a weak one, or even wounds existed.

With reference to the elbow-joint,

Dr. BRIDGON doubted the propriety of subperiosteal excision, because by so operating it was much more difficult to obtain a mobile articulation than by the old-fashioned method of resection. There was an exuberance of bony growth that interfered with subsequent motion. With regard to the flail-like joint, it was probably much more useful than patients usually supposed.

He then referred to a case in which the forearm could be swung about and made to assume almost any position. A stiff angular splint was applied, and, by the aid of that, the patient was able to perform considerable labor. A few months afterwards the patient discovered that she could perform her work without the splint, and from that time she continued to use her arm without any artificial support. He thought the usefulness of the arm was greater than it would have been had a less amount of bone been removed, and more limited motion obtained. He believed that surgeons many times failed by reason of removing too little bone. The result in Dr. Lange's case was remarkable in view of the extent of the injury.

Dr. LANGE remarked that after subperiosteal excision there was a greater indication for early passive motion than after the other operations.

MICROSCOPICAL STUDIES ON ABSCESS OF LIVER.

Dr. C. HEITZMANN exhibited microscopic specimens illustrative of suppuration of the liver, which subject

had been studied in his laboratory by Dr. J. C. Davis. Dr. Davis had found clinically that, with the exception of traumatic suppuration and that caused by parasites, in all probability abscess of liver was always due to embolism, mainly of the portal veins. The inflammation started invariably in the interstitial connective tissue, and consecutively a part of, or a whole lobule, or even a number of neighboring lobules, might be engaged in the formation of an abscess. In the interstitial connective tissue, the living matter, both in the protoplasmic bodies and in the basis substance, was considerably augmented, and appeared in the shape of coarse, shining, homogeneous granules, which themselves were transformed into inflammatory or medullary elements. The elements were at first uninterruptedly connected with each other by means of delicate threads of living matter, and only after rupture of these threads had taken place the medullary elements became isolated, and then represented pus-corpuses. The liver epithelia first exhibited a coarse granulation and augmented nuclei from the increase of living matter. A number of them might be fused together and divided again into medullary elements, which, if isolated, also shared in the production of pus-corpuses. No emigration of colorless blood-corpuses could be made out. Around an abscess of longer standing, a connective tissue capsule was formed by the medullary elements, which in that instance remained connected, became spindle-shaped, and were partly transformed into a striated or homogeneous basis substance.

FATTY DEGENERATION OF THE PLACENTA.

DR. PUTNAM-JACOBI presented a placenta for the purpose of obtaining further knowledge regarding the now mooted question of fatty degeneration of that organ.

A woman who had been married five years, and, to her knowledge, had never been pregnant, ceased to menstruate six months ago. At the first two menstrual epochs succeeding the cessation of menstruation she suffered from violent attacks of sick-headache. Except for that, her general health was good, and she gave none of the usual signs of pregnancy. In the fourth month after the cessation of menstruation she sustained a fall. It was not severe, but was followed by a sensation "as if something had been torn away from the inside." She, however, experienced no special pain, and had no special symptoms otherwise. She had a moderate enlargement of the abdomen, which she had noticed for only about three months after the cessation of menstruation. On examination, a tumor was found in the abdomen, at least two fingers' breadth below the umbilicus, and corresponding in size to a uterine tumor at the fourth month of utero-gestation. Placental souffle could be distinguished, but the fetal heart was not heard, nor had she felt anything like fetal movement. Dating from the cessation of menstruation, the presumption was that the fœtus was destroyed about the fourth month of intra-uterine life, and the size of the tumor corresponded with that view. That diagnosis was confirmed a few weeks later, when miscarriage occurred, which resulted in the delivery of a macerated fœtus of about four months. The point of special interest in the case was the condition of the placenta. It was delivered almost immediately with the fœtus. It was small, the blood-vessels were shrivelled, there was no large apoplectic clot, but through it were disseminated very small points of apoplexy. About three-fourths of the placenta was converted into a yellow and apparently fatty mass.

DR. HEITZMANN remarked that the specimen, like others which he had examined, presented the gross appearances of fatty degeneration; but the microscope had revealed the fact that it was an amyloid change.

He had the day before examined the seventh specimen of so-called fatty degeneration of the placenta removed by miscarriage at the seventh month, and it was found to be the seat chiefly of waxy degeneration, with only a slight amount of fatty change.

FALLOPIAN PREGNANCY WITH CORPUS LUTEUM IN THE OVARY UPON THE OPPOSITE SIDE.

DR. E. G. JANEWAY presented a specimen that illustrated extra-uterine fetation occurring with the fœtus in the Fallopian tube opposite to the ovary in which corpus luteum existed. The uterus, with its appendages, was taken from the body of a woman thirty-two years of age, who had been sick about fifteen hours, the chief symptom being pain in the abdomen. She died in a state of collapse.

At autopsy about two quarts of blood were found in the abdominal cavity, partially coagulated, the coagulation being most marked in the portion contained in the pelvis. In the left Fallopian tube, at its anterior border, was seen a small linear rupture, not more than one-eighth of an inch in length, from which the blood escaped.

The embryo was not more than one-eighth of an inch in length, and was simply a small, whitish mass upon the alantoid vesicle. The entire sac was about an inch in length, and laid in a distended Fallopian tube, which was a trifle larger, and contained some blood-clots in its interior.

The explanation offered in many of these cases had been that the ovum escaped, and, wandering about in the abdominal cavity, finally entered the Fallopian tube upon the opposite side. That explanation was not admissible in the present case, because, as a result of former pelvic peritonitis, each tube was bound to its corresponding ovary, leaving no opening through which an ovum could enter. Another explanation which some had accepted, was that the ovum, finding its way into the cavity of the uterus, passed across and entered the opposite Fallopian tube. That explanation, however, Dr. Janeway believed should be taken *cum grano salis*. In the present case he thought we were restricted to the explanation that an ovum escaped from each ovary, and that a corpus luteum developed only in the ovary opposite to the one which furnished the impregnated ovum, as in that ovary there was found a sac, about one-half inch in diameter, which was filled with a pulpy blood-clot, evidently of about the same age as the corpus luteum found in the opposite ovary. That blood, when examined under the microscope, showed no hæmatoidine, hence it was probably not more than seventeen or eighteen days old.

In the opposite ovary there was found a beautifully developed corpus luteum, with bright yellow convoluted wall and fresh red blood-clot in the centre, and corresponded in size to the corpus luteum about three weeks after menstruation.

COMPOUND DISLOCATION AND FRACTURE OF THE ANKLE-JOINT—RECOVERY WITH GOOD MOTION.

DR. J. W. HOWE presented a patient who had sustained a compound dislocation and fracture of the ankle-joint. On the 13th of February, 1879, a large mass of timber fell upon the man, striking him above the knees, and producing a simple fracture of the tibia and fibula of the left leg, and a compound fracture and dislocation at the right ankle-joint. The

joint was opened by the injury; the lower portion of the tibia was broken into two pieces, and the upper fragment protruded from the wound. The man was admitted to the St. Francis Hospital, the limb was treated antiseptically, and the only rise in temperature occurred the next day after admission. He suffered no pain, was able to leave his bed at the end of eight weeks from the time the injury was received, and walked about the ward. The case terminated without synovitis or ankylosis, and the joint movements were free. In the early part of the treatment the limb was kept in a simple fracture-box.

Dr. BRIDGON remarked that before the days of antiseptic treatment according to Lister, it was regarded as good treatment in such cases to excise the ends of the bones. He had not seen a patient who exhibited so good a recovery in so short a period of time as in the case presented. Probably the Lister plan should be credited for much of the result, but at the same time the favoring influence of the man's vigorous constitution must be taken into consideration. If, for any reason, the Lister plan could not be made available, he should, in these cases, excise the ends of the bones.

The Society then went into Executive Session.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, June 23, 1879.

DR. A. E. M. PURDY, VICE-PRESIDENT, IN THE CHAIR.

A REMOVABLE PAPER BRACE FOR THE TREATMENT OF POTT'S DISEASE AND LATERAL CURVATURE.

DR. A. M. VANCE read a paper on the above subject, which has been published in the RECORD. (See vol. xv., No. 25.)

The paper being before the Society for discussion,

DR. F. H. HAMILTON remarked that he had had the pleasure of examining the apparatus, and his opinion was that it was an excellent apparel, that Dr. Vance was working in the right direction, and that it was doing away with some of the disadvantages of the excellent apparel plaster-of-Paris. Plaster-of-Paris had in its favor exceeding simplicity and facility with which it could be applied. Exceptionally, almost any man could learn to apply it, but it was liable to break down a little more so than was desirable, and covered the parts so thoroughly that we could not tell what was going on beneath it.

Another objection to the plaster-of-Paris jacket was that it was to be constantly worn. Perhaps Dr. Sayre would regard that as an advantage, and he did not wish to speak contradictory to his experience; but it was his (Dr. H.) opinion that it was better to occasionally remove the apparel, in order to avoid complete atrophy of the muscles. That had really been the great reason why surgeons had looked in another direction for immovable supports which were to be applied to the spinal column and to other parts of the body, in order that the muscles should retain their power.

But such appliances also possessed their disadvantages. His impression was that, beginning with the plaster-of-Paris, we were working in the right direction, because it gave us an apparel which enclosed the entire body, and consequently had many points of support. An apparel that had only a few points of support was liable to give rise to discom-

fort, sometimes to ulcers, and he thought that ordinarily they did not give so much support as those which encircled the body completely. That was why he commonly used a movable corset, an apparel designed by the late Dr. Jacob A. Wood.

Dr. Hamilton thought it was in that direction that we were to look for proper support for the spinal column. If an apparatus could be perfected which was simple, and could be adjusted by everybody, we would have attained a very great desideratum. As it was, physicians were compelled to send their patients to specialists. He commended Dr. Vance's apparel as a work in the right direction. It was somewhat more complex than the plaster-of-Paris, but much more easily made than those forms of apparel which were chiefly composed of metals, and only made by mechanics and expert specialists.

DR. LEWIS A. SAYRE remarked that he had applied the plaster-of-Paris jacket hundreds, if not thousands, of times, and he had yet to see an excoriation produced by it, or a breaking down of the apparatus, as referred to by Dr. Vance. He was always careful to use good plaster and a certain kind of shirt, a knit garment, one which could be applied with skin-fitting accuracy. He was so much pleased to see this step in the right direction, and recognized in it so much improvement upon the iron brace, the "crib," as he had called it, employed in the institution with which Dr. Vance was connected, that he felt almost like giving it his entire commendation. But, in justice to himself and to the plan which he had suggested, it seemed necessary to say a few words. Dr. Hamilton had very justly remarked that the great desideratum in the treatment of spinal disease was to get something which properly fulfilled the indications, and at the same time was so simple that medical men in all parts of the world could use it without being compelled to consult mechanics or specialists. Dr. Sayre believed that the plan of treatment which he urged was such that, if any medical man would follow out his instructions minutely to the letter he could not fail of obtaining success. For it had given the most satisfactory results, not only in his own, but in the hands of many others, and therefore, inasmuch as it had acted so favorably, he did not see any necessity for complicating it by Dr. Vance's apparatus. It was perhaps true that Dr. Vance's apparatus was lighter than the plaster-of-Paris jacket, but in all other respects it had no special advantages over it. In order to make the paper brace, it was first necessary to learn to apply the plaster-of-Paris jacket properly, to secure an accurate fit before commencing to build the brace, and when that was done, what more could be wished for? For, when the first good-fitting jacket was obtained, it was better than any other that could be produced.

Dr. Sayre then described what he meant by a properly fitting jacket, and it was one that was *smoothly adjusted to every inequality on the surface of the body*. In order to obtain such a jacket it was necessary to merely unroll the bandage with one hand, while with the other it was moulded over each inequality, over this elevation and into that depression, and when applied in that manner it could not irritate the skin. It was the pressure on the *summits* of the little elevations all over the body that very commonly gave rise to excoriations, but such pressure was the result of improper application of the bandage. For example, if a roller was drawn over the knuckles, it would only touch their summits, and therefore make undue pressure upon four points; whereas, if the roller was simply *laid* over them, and then *moulded* into the de-

pressions and over the elevations, the pressure would be evenly distributed, the support would be greater, and the tendency to produce excoriations avoided. When excoriations occurred, they were simply the result of improper application of the jacket. Dr. Vance had stated that he scraped off the inequalities on the inside of the model, preparatory to making the paper brace, and he (Dr. S.) regarded that as the worst thing that could be done, for the very inequalities were among the essentials to a properly fitting and supporting jacket. Dr. Sayre, therefore, believed that it was wiser to allow the first accurately fitting jacket to remain than to take the additional trouble of removing it for the sake of the risk of obtaining one which possibly might not fit. Besides there was a loss of time and money in making the exchange.

Again, Dr. Vance had spoken of the advantage arising from the fact that his apparatus could be removed and reapplied at any time without much trouble. That was true, but the very fact that apparatus in general, designed for treatment of spinal disease, was *movable*, was one of the strongest objections to it. The very fact that the plaster-jacket encircled the trunk entirely, and, when properly applied, could be worn with comfort for months, thereby giving absolute quiescence to the diseased parts and an opportunity to get well, was one of the greatest advantages the apparatus possessed.

Dr. Sayre then read from Dr. Golding Bird's writings, in which he stated that from personal experience in forty cases he had not seen any ill effects produced by the plaster-jacket; that sore backs and chafes from the jacket were due to fault in putting it on; that out of seventy jackets he had seldom seen the skin irritated; that the jacket should not be removed; that it was the integrity of the plaster which constituted its perfection; and that as soon as cut up it became but little better than old apparatus.

From the *Berliner klinische Wochenschrift* for May 12th and 19th, 1879, Dr. Sayre also read the statements of Walzburg to the effect that the condition of the skin testified that it was not materially injured by the plaster-jacket, and that a movable jacket in the treatment of kyphosis should not be recommended.

Dr. JOHN A. WYETH thought Dr. Vance's apparatus was a step in the right direction, but he was not disposed to accept any one device as the *ne plus ultra* in the treatment of Pott's disease. He thought that all cases of the disease occurring above the fourth dorsal vertebra required for successful treatment some form of head-suspension. Cases in which the disease occurred between the fourth and the eleventh dorsal, could be best treated by some apparatus that fixed the thorax. He thought Dr. Vance's brace would succeed in that class of cases, and it had the advantage of being lighter than the solid plaster-of-Paris jacket, which would do the same thing, but had the disadvantages he had discussed upon another occasion. [See RECORD, vol. xv., No. 6.]

Dr. Wyeth objected to the term absolute quiescence, for he did not believe that any apparatus could be applied to the human trunk and be worn and give absolute quiescence. If, therefore, there was not absolute quiescence, there was danger from friction incident to the movements of respiration. It was there that the great danger attending the use of Dr. Sayre's jacket rested. He did not wish to detract from the value of the apparatus in the least, for it had already done and would do, great good, but it was not every one who knew how to use it properly.

The cases in which the disease was from the eleventh dorsal vertebra below, he believed could be best treated by means of his own apparatus.

Dr. A. C. POST remarked that a case in which the plaster-of-Paris jacket occasioned excoriations occurred under his own observation. The child had considerable deformity, and the mother stated that the jacket had been applied at Bellevue Hospital, but that the child could not wear it because it made the back sore. Dr. Post induced her to take the child to Dr. Sayre's office, where a jacket was applied which not only occasioned no distress, but was worn with great comfort. There was undoubtedly a lack of skill which gave rise to these inconveniences.

The mixture of glue and oxide of zinc, suggested by Dr. Vance, was the same as recommended by Dr. Hayes Agnew, of Philadelphia, at the meeting of the International Medical Congress in 1876.

Dr. V. P. GIBNEY remarked that, so far as his experience went, Dr. Vance's brace was an improvement on the plaster-of-Paris jacket, in that it could be easily removed and reapplied. He thought Dr. Sayre did not mean to say exactly that he wished to have the plaster-of-Paris get into every inequality on the surface of the trunk, for if so the ribs could not act in the physiological processes of respiration. During the last two or three years he had taken pains to inquire who put the plaster-jacket on when a patient came to the Hospital for Ruptured and Crippled, and complaint was made that it could not be worn. So far as his experience went he had found a number of cases in which excoriations had been made when the jacket had been applied by men whom Dr. Sayre would regard as experts.

As to the excoriations produced by the steel brace referred to, he did not wish to discuss that question that evening. Testifying cases could be found for every kind of apparatus, but for it he could say that it was an instrument well adapted to meet the wants of the general practitioner in every part of the country. Dr. Vance's apparatus also met the main indication in the treatment of all bony diseases of the spine, namely, fixation, and there was one objection to the plaster-of-Paris which was obviated by its use. He knew of one case in which the plaster-of-Paris jacket had been worn five years, and if it was now removed the child could not walk at all. For such a case an apparatus that could be easily removed and reapplied was preferable to an immovable apparatus.

Dr. SAYRE remarked with regard to the plaster-of-Paris filling the intercostal spaces and thus preventing motion of the ribs, consequently interference with respiration, that if any one would study Hilton on Rest, they would there find a case reported in which diaphragmatic respiration was carried on for years without special inconvenience to the person; there was complete consolidation of the ribs with the spinal column, allowing of no motion whatever.

If it was desirable to have an apparatus that could be removed and reapplied, the plaster-of-Paris jacket could be cut down, its edges bound, eyelets adjusted, and then it was as convenient as the removable paper brace.

Dr. HAMILTON remarked that he did not think it possible that any form of apparel which grasped the ribs, movable as they were, even if not used further than for purposes of suspension, could be constructed which, having its prehension upon the circumference of the chest, would uplift the spinal column. He suspected the error in the principle of the apparel was, that it pushed, although it pushed equally upon all sides of the body, but it did not uplift. So far he did

not agree with Dr. Golding Bird in his view of the action of the plaster-of-Paris.

DR. SAYRE remarked that the plaster-jacket neither lifted nor pulled. The patient was simply suspended until he felt comfortable, and then the apparatus was applied to fix him in his improved position—it was simply fixing the position given to the patient before the jacket was put on, the apparatus neither shrinking nor stretching.

DR. WYETH asked Dr. Sayre if he believed the spinal column could be extended.

DR. SAYRE replied that he not only believed, but that he knew it.

DR. WYETH asked why suspend the patient before applying the plaster-of-Paris jacket?

DR. SAYRE said because it relieved the diseased parts from pressure, and made the patient more comfortable, and when in that relieving position he applied the jacket, which prolonged his comfort.

DR. WYETH remarked that since one-fifth of the entire length of the vertebral column was composed of intervertebral (elastic) fibro-cartilage; since the articular processes were surrounded by capsular ligaments (which anatomically implied free motion) lined by synovial membrane; since the length of the body was increased in the recumbent posture (the superincumbent weight removed, he must maintain the spinal column was susceptible of being extended or shortened by applying the proper force.

DR. VANCE, in closing the discussion, remarked that he had not seen a close fitting of the intercostal spaces by the plaster-of-Paris jacket. Besides, suspension raised the hump, and when the suspension was removed the lower part of the hump at once impinged against the plaster, and it was just there that excoriation was most liable to occur. He then referred to what he conceived to be the difficulties attending the application of the plaster-of-Paris jacket with the aid of suspension.

The Society then adjourned.

Correspondence.

PARONYCHIA—RESTORATION OF TERMINAL PHALANX.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In the RECORD, No. 439, April 5, 1879, p. 334, in your report of the Surgical Section of the New York Academy of Medicine, under "Paronychia—Restoration of Terminal Phalanx," the question was raised, Would a new phalanx be formed? (*vide* report). Soon after the publication of the report I received from Prof. Frank H. Hamilton, one of the distinguished surgeons of our profession, this communication, which I appreciate most highly: "Dear doctor, if you will call upon me I will refer you to a number of published cases of restoration of the last phalanx, after opening a felon." I called the following week, when Prof. Hamilton gave me the following references:

First. In the *Buffalo Medical Journal*, Vol. V., 1850, p. 710, a case reported by him, in which there was reconstruction of the entire terminal phalanx of the thumb. In this report he gives to the late Prof. Dudley, of Lexington, Ky., the credit of priority.

Second. In the same journal, Vol. XI., 1855, p. 257, an article entitled, "An Analysis of Cases of Paronychia, by Austin Flint, Jr., Buffalo, N. Y." These are

taken from the private records of Prof. Hamilton, eighty-one cases of paronychia benigna, and seven of paronychia maligna. This analysis does great credit to the undergraduate Flint (his graduation is recorded 1857), and is well worthy of careful perusal at the present day. A partial epitome may not be out of place. He discusses sex, occupation, causes, hand and finger affected, age, health, suppuration, time of opening. His concluding remarks are as follows: "These facts show the importance of opening the finger at least as early as the tenth day, and it would appear proper to do so as soon as the disease has become established, even before pus has been formed."

Third. In the *New York Journal of Medicine*, Vol. IV., 1850, New Series, p. 139 (edited by Dr. S. S. Purple), at the close of the first article in the surgical department is a selection from the *Transylvania Medical Journal* for December, 1849, on the treatment of gunshot wounds, by Prof. B. W. Dudley, where he states that after removal of the dead phalanx, the result of bone-felon, in very many instances, he assisted nature in the complete restoration of a new phalanx by the roller: "I have within the last quarter of a century, in very many instances after the extraction of an entire dead bone, caused the construction of a new one in its place, of equal dimensions, by the aid of the roller, which suspended muscular movement, subdued swelling and inflammation, and thereby left nature free to reconstruct the lost bone. The dead phalanx, in cases of bone-felon, is here referred to."

Fourth. The *Peninsular Journal*, Vol. V., p. 372, January, 1858. This journal I have been unable to consult. I regard the act of Prof. Hamilton as one tending to cement the profession, and worthy of commendation and imitation, for by it my knowledge of the results and the treatment of paronychia has been better established.

In a practice of about twenty-five years I have had considerable experience in the treatment of paronychia, but the case to which I have referred is the first in which I have had occasion to remove dead bone.

Although my plan of treatment was original with me, being guided solely by my judgment in obtaining as good result as possible, thereby having "a good little hand" (the name I heard the renowned Dr. Valentine Mott give the thumb), I discover similar treatment was used over a half-century ago by the late Prof. Dudley.

How often in emergencies we think we are geniuses, viz.: we invent an instrument, and with the kind aid of the instrument-maker it is made presentable, but at the same time he may inform us that our invention was presented years ago.

The very estimable analytical paper on paronychias by the undergraduate Flint was a forerunner of his brilliant analytical career as a physiologist. Of Prof. Dudley it may be said, "though dead, he yet lives."

From the references given to me by Prof. Hamilton I have derived benefit, and therefore wish, through the columns of your valuable journal, with its wide circulation, to extend the information to others.

Yours very respectfully,

FRANCIS V. WHITE.

NEW YORK, July 28, 1879.

THE LONDON TEMPERANCE HOSPITAL.—This is an institution which treats its patients without alcohol. Its sixth annual report is just out, and claims that the hospital is very successful in carrying out its peculiar methods. We find no statistics or details given, however.

THE TREATMENT OF YELLOW FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Notwithstanding the sanitary precautions taken by the various "Boards of Health," yellow fever seems determined to push its way into southern society. The experience of last year is sufficient evidence of the helplessness of physicians (with those means already used) to check its progress. The "cold-water" treatment was the last resort. In some cases it appeared to operate finely; in others disastrous results followed its employment.

In all the articles, statements, etc., I have read in regard to the successful administration of cold in yellow fever, improvement dates from profuse perspiration. Some claim that to the direct refrigerant action of cold the benefit is to be traced; but practical experience indicates the first statement to be correct. Assuming this to be the fact, the question arises whether there are no safer means at our command to bring about the same results. Unquestionably there is such a remedy in the proper and energetic application of external heat. By this, no reference is made to the wrapping of a patient in a blanket or two, and the induction of a mild perspiration; but to the vigorous and thorough administration of heat, such as is found in the Turkish bath, etc., where the temperature varies from 120° to 220° Fahr., and *excessive* sweating is produced. Let us briefly analyze the action of cold and heat upon the system. The first effect produced by the former is a shock, which for the time being paralyzes the nerves controlling the cutaneous pores, throws the blood to the visceral, and increases their congestion. In a short time a reaction *generally* sets in, the blood flows to the surface and relieves visceral congestion, the pores of the skin are opened and sweating ensues.

Upon the application of heat the blood leaves the visceral and seeks the surface. The pores are opened, sweating ensues. The same result may be reached in each case, but which is safer? With cold, the patient is liable never to recover from the shock, in which case death occurs. With heat, there is no shock from which to recover.

Pathological investigation in yellow fever last year showed excessive visceral congestion. The liver, spleen, brain, choroid, etc., were in an extremely inflamed condition, and the kidneys so filled with albuminous tube-casts as to almost, if not quite, prevent any secretion of urine whatever. Is it justifiable in this condition to submit a patient to any procedure which further induces, if only for a short time, congestion? If reaction sets in upon the administration of cold all may be well, but if the contrary occurs (and this is often the case), a fatal result may with safety be predicted. The "cold-water" treatment of fever is losing favor. The splendid results anticipated from its adoption have not been fulfilled, and statistics from various hospitals do not in many instances compare favorably with even expectant treatment. I read with pleasure an article in the RECORD of May 31, 1879, by Dr. Peters, of Cohoes, N. Y. To this article I would refer those interested in the subject under consideration. The statistics he has compiled derogatory to the "cold-water" treatment are very valuable, and show clearly that this remedy is not realizing the expectations of its advocates.

If the pathological condition of yellow fever is congestion, clearly any remedy capable of relieving this condition would be at least valuable and worthy a fair trial. If space allowed, many proofs of the effi-

caety of heat in this particular might be adduced. I will, however, cite but one instance, which seems most scientific and satisfactory.

Dr. Leared, of England, relates the following: "Having found that persons affected with fulness and congestion of the head were often much benefited by the Turkish bath, he thought that the readiest mode of ascertaining the effect of the latter upon the cerebral circulation would be by observing its influence upon the blood-vessels of the retina. Mr. Wordsworth therefore examined Dr. Leared's eyes with the ophthalmoscope, just prior to his entering the bath, and again after he had remained in the hottest chamber (196° Fahr.) for a quarter of an hour, and then found a decided and marked paleness of the optic nerve and a diminution in the size of the retinal vessels. The same effect was noticed in four persons employed in the bath (a negro, an East Indian, an Englishman, and a German), under a temperature of 120° Fahr., who were examined at the same time by Mr. Wordsworth." These experiments I have verified in a patient (F. E., male, aged 24 years, Sycamore, Ill.) under my care for congestion of the brain. A Turkish bath not being convenient, an alcohol and water-vapor bath was substituted. The optic nerve and retina being noticed before and after profuse perspiration, apparently the same effects were produced as in Dr. Leared's case. If the fever becomes epidemic this year, I would strongly advocate the adoption of the external application of heat as the main feature in its treatment. The erection of a chief building, where the principles of the Turkish bath, viz., sufficient heat and ventilation, could be administered, or in lieu of this, the application at home of heat in the way of "corn sweats," "alcohol sweats," etc., would answer a good purpose, provided they were given often enough and with sufficient vigor. If Turkish bath buildings should be adopted, it would be advisable to have physicians in charge who understand its principles and practical application.

The past has not been productive of good results in the management of yellow fever. It appears, therefore, that any remedy indicating better issues should receive attention and a fair trial. One fact, however, must be borne in mind in order to obtain good results: the remedy must be administered *very thoroughly*, and not by the occasional induction of a mild perspiration.

FRANK ALLPORT, M.D.

SYCAMORE, ILL.

ELECTRO-THERAPEUTICS AND THE AMERICAN NEUROLOGICAL ASSOCIATION.

REPLY TO DR. J. D. S. SMITH.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The strictures made by Dr. Smith in his letter concerning Electro-therapeutics and the American Neurological Association were not altogether unjust. It cannot be denied that the whole discussion on current direction and polar influence, as reported, tends to convey the impression that there are no well established differential indications for their use. Since of all remedies electricity is used with the least understanding by the many, I think it peculiarly unfortunate that in this discussion there was such a wide difference of opinion; and as my conviction in relation to this question is very positive, I very gladly take this opportunity to repeat and emphasize it. I then stated that in most cases where a

sedative influence was to be desired, and for the relief of pain associated with true neuralgia, as defined by Anstie, the descending current was far preferable, and that in numerous cases the ascending current was not only valueless, but actually aggravated symptoms which yielded readily to an opposite direction of current. My own experimental attempts, which I published years ago, were sufficiently convincing to me, and afforded a basis on which I have since satisfactorily acted.

In a number of cases which I tested, I was enabled, after obtaining good results from the descending current, to increase the pain temporarily by changing its direction. In the first case my observation was accidental, for, having under my care a severe case of facial neuralgia, which was slowly recovering under descending currents, I changed the position of the poles, hoping in this way to hasten the results. The effects were disastrous, for the pain instantly returned with increased severity. Whether such results, both good and bad are due mainly to polarization or current-direction is open to question. According to the well-known contraction laws of Pflüger, we might well believe that polar influence is the important factor; and yet the French school, and notably Legros and Onimus, deny the efficacy of polar influence in exciting physiological phenomena, ascribing them chiefly to current direction. They ascribe anelectrotonic effects to electrolytic action, and to the induction of currents of polarization. Whatever the truth may be, however, in regard to this, I have no more doubt about the different therapeutic effect of opposite directions of current than I have of the difference between the two forms of current.

A. D. ROCKWELL, M.D.

NEW YORK.

New Instruments.

NEW OPERATION IN CASES OF PROLAPSUS RECTI AND EXTERNAL HEMORRHOIDS.

By SIMEON N. LEO, M.D.,

NEW YORK.

THAT there are certain painful and serious affections of the lower portion of the rectum amenable to surgical treatment and interference is pretty well understood, and the attention of late bestowed on the practice of this now almost so-termed specialty has given rise to a series of suggestions and operative procedure, all well in their way, though some of them, in skilful hands, are entitled to a preference, bearing in mind the fact that modifications must be made to meet the requirements of any particular exigency. Without, therefore, entering into a discussion of rival claimants as to whether the clamp and cautery, caustic, cutting, or ligature are more desirable, I briefly beg to recall to mind the anatomical structure and relation which the outlet of the lower gut bears to other parts in the male and female organism, especially that portion most frequently invaded by the two varieties of external piles appropriately described—firstly, as hypertrophies or excrescences of the skin; secondly, as sanguineous or venous tumors; and suggest that in view of danger from cutting and other operations, which often give rise to troublesome hemorrhage and tetanus, that the ligature is preferable, as safer, while yielding the best result, and less likely to provoke some of those disagreeable sequences which surgeons

who have given the various methods referred to a trial are more or less familiar with.

Having resolved, then, to remove such growth or extruded part by ligature, it is well to consider some of the more important features associated even with this simple operation, which in some respects I believe can be so modified as to suit both patient and surgeon, affording the former greater ease and comfort in its performance, and the latter the satisfaction of having discharged his task in the most acceptable manner possible, requiring but little time and inducing many considerations, to which the brevity of this article simply allows allusion. I suggest the use of the little instrument two inches and a half in length, one inch

and a half in width, illustrated by the woodcut, bearing in mind the following directions in its application:

Firstly, the person to be operated on should be careful to have the gut well washed out with an enema of warm water, and while evacuating same protrude the parts to be taken off. Then placed upon a bed or lounge, resting on the right side, with the knees flexed up and directed to bear down, it is well then to have the upper buttock raised, if an assistant is present, by him, otherwise supporting it with a doubled pillow; then seize the hemorrhoids with a forceps, serrated hook, or vulsellum, and pulling the mass gently out see if the piles be surrounded with much submucous or muscular tissue; if so, separate each pile with a stout scissors, being careful not to wound any of the vessels, cutting parallel with the bowel for a short distance only; then insert the tube, well oiled or greased, at A, its sharp point, and directing the assistant to make gentle traction and pull forward on the projecting parts. With a catgut ligature proceed to tie firmly the mass in the grooves, B, C, and D, according to their length.

It is well to put a tight, double ligature at the groove, B, so as to strangle the extraneous parts. The operation is then concluded. A thin probe should be inserted at F to free the tube, after which a sedative opiate injection may be used to allay pain; while at the time it is advisable to administer an astringent pill or draught for the purpose of confining the bowels.

The tube being hollow allows the flatus to escape from the canal, permits local medication, sedative and antiseptic; and the gentle pressure exerted on the sphincter muscles being rather soothing and supporting than otherwise.

The instrument should be so entered that the two flanges are placed transversely to the median line. The surrounding parts, as a rule, heal rapidly, and the sloughing, which occurs in a few days, generally releases that which it is desired to remove.

A prolapsus of the rectum may be treated on pretty much the same general principles, and I believe will yield equally satisfactory results.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 3 to August 9, 1879.

WEBSTER, WARREN, Major and Surgeon. Granted leave of absence for three months. S. O. 181, A. G. O., August 5, 1879.

HARVEY, P. F., Capt. and Asst. Surgeon. Relieved from duty at Ft. Buford and assigned to duty at Ft. Randall, D. T., relieving Asst. Surgeon L. Crampton. S. O. 84, Dept. of Dakota, August 2, 1879.

CRAMPTON, L. W., 1st Lieut. and Asst. Surgeon. When relieved from duty at Ft. Randall, to proceed to Ft. Buford, D. T., and report to the Post Commander for duty at that post. S. O. 84, C. S., Dept. of Dakota.

RICHMOND, CHAS., 1st Lieutenant and Asst. Surgeon. Having reported in person at these headquarters, assigned to temporary duty at Ft. Buford, D. T. S. O. 83, Dept. of Dakota, July 30, 1879.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending August 9, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Aug. 2, 1879.	0	5	34	3	44	19	1	0
Aug. 9, 1879.	0	7	40	2	25	17	1	0

THE YELLOW FEVER.—From August 6th to August 12th, inclusive, the number of new cases of yellow fever in the city of Memphis was 161, and the number of deaths 32. The whole number of cases for this year to August 13th is 422, and the whole number of deaths 106.

By order of the Secretary of War, 500 army tents have been forwarded for the use of fever refugees in camp.

The disease has extended beyond the immediate neighborhood where the first cases developed in July, and cases have been reported and deaths have occurred in so many different localities in the city, that the Board of Health, on August 9th, made a formal declaration of a general epidemic.

In this port (New York) a few new cases have been received at the hospital on Dix' Island. August 12. All the patients have been discharged.

One fatal case has occurred in the city of Brooklyn. Dr. White, Sanitary Inspector for the city of New Orleans, reports that the city is enjoying the highest possible health.

A very severe epidemic is reported from Tampico, Mexico.

VOLUNTEER SURGEONS FOR YELLOW FEVER SERVICE.—The order which assigned Surgeons Thomas Hiland and Walker K. Schofield to duty as volunteer surgeons for yellow fever service, under the direction of the National Board of Health, has been revoked, neither having had the fever. Medical Inspector Somerset Robinson, of the Navy, and Dr. Daniel M. Burgess, a resident of Havana, have been assigned to duty at Matanzas and Havana respectively, to perform the duties of inspectors.

THE TREATMENT OF CHOLERA-INFANTUM.—Dr. Charles H. Avery, of New York, writes that he has adopted the following treatment in cholera-infantum with very great success: He first directs that a poultice be made as follows, and applied over the stomach: Take of pounded cloves, cinnamon, and ginger, each, one teaspoonful, add a small quantity of flour, and then moisten the whole with brandy. Spread the mixture on and cover with thin flannel, and so fasten it that it will be kept in position. Occasionally moisten the poultice with brandy, which can be done without removing it. One teaspoonful of the following mixture is then ordered every two hours for children over three months old.

- B. Acid. carbol.....gr. xxiv.
- Spts. vini.....gtt. xxiv.
- Aq. menth pip..... $\frac{3}{4}$ iss.
- Mucil. acac..... $\frac{5}{8}$ vi.
- Syr. papaver..... $\frac{5}{8}$ vi.
- Tr. opii.....gtt. x. M.

As a rule the vomiting ceases before the hour arrives for the administration of the third dose; frequently before the second dose is given.

The passages from the bowels are not arrested by the medicine, but within twenty-four or forty-eight hours they begin to change in character, soon diminish in frequency, and afterwards cease altogether. The diet of the child is restricted to barley-water and milk. If it is a nursing child, barley-water is administered before it is allowed to take the breast.

If the vomiting is severe, the child is *not allowed to take anything*, except the medicine, for three hours.

If there is marked evidence of acidity of the digestive tract, teaspoonful doses of the following mixture are given every ten or fifteen minutes for two or three hours:

- B. Mistura cretae..... $\frac{5}{8}$ ij.
- Syr. rhei..... $\frac{5}{8}$ i. M.

To this he sometimes adds fifteen grains of hydrarg. cum creta.

As a substitute for the above antacid mixture, he sometimes gives ten grains of subnitrate of bismuth, and five grains of pepsin three times a day.

The leading features of the plan which he recommends are: the spice poultice, the barley-water and milk diet, and the medicines according to the first prescription.

HONOR TO DR. CRAWFORD W. LONG.—Mr. F. B. Carpenter, of New York, has just finished a nearly full-length portrait of Dr. Crawford W. Long, late of Athens, Ga., which is to be placed in the State Capitol at Atlanta, Ga., at the order of the alumni of the Georgia University. It is in honor of the discovery made by Dr. Long, March 30, 1842, that inhalation of sulphuric ether renders a patient insensible to the pain attending a surgical operation. It will be received and presented to the Georgia legislature by United States Senator Gordon.

Original Lectures.

RETENTION OF URINE IN ELDERLY MEN.

CLINICAL LECTURES DELIVERED IN BELLEVUE HOSPITAL,

By J. W. S. GOULEY, M.D.,

PROFESSOR OF DISEASES OF THE GENITO-URINARY SYSTEM, MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Reported for THE MEDICAL RECORD.)

LECTURE I.

ACUTE RETENTION OF URINE.

GENTLEMEN:—I propose, in a few short lessons, to speak to you on the subject of retention of urine as it sometimes occurs in elderly men, for I have already, on previous occasions, said much concerning the occurrence of this distressing trouble in the young and middle-aged.

The class of cases to which I now invite your attention may be illustrated by the following, and not infrequent history. I might give twenty or more examples, but for the present a single typical case will suffice.

On an unusually cool evening in August, 1878, a gentleman, 54 years old, in fair health, clad in thin summer garments, sat for several hours upon the piazza of his house near the shore of one of our lakes. Before retiring he experienced a sensation of general coldness, which was not, however, followed by an absolute chill. On the next morning he suffered the greatest distress from inability to pass a single drop of urine, and ever since that moment he has not been able to void his urine without the aid of a catheter, though he had never, before this attack, had the slightest difficulty in relieving his bladder naturally. This patient was then suffering from what has been properly called acute retention of urine, which should not be confounded with the more gradual and insidious accumulation of urine known as chronic retention.

In the clinical study of a case of acute retention of urine the following are the points to be considered: An elderly man, otherwise healthy, having never had any symptoms of trouble with his genito-urinary apparatus, is, after exposure to cold in the way just described, or after a debauch—especially if followed by coitus—unable to relieve his bladder and suffers great pain from distention, though at the outset of the retention he may have been able, by much straining, to expel now and then a few drops. The first question that, I am sure, arises in your minds is, what may be the mechanism of such retention? This stoppage of urine is not the consequence of closure of the canal by a stricture, for there are no strictures of the prostatic portion of the urethra or of the urethro-vesical orifice, and it is easy to exclude impacted calculi, or other foreign bodies, by a simple exploration, and also by further inquiry into the antecedents of the case. The condition in question is similar to that which occurs in young men who, towards the decline of an attack of gonorrhœa, have suffered exposure to cold, and consists in complete occlusion of the urethro-vesical orifice and prostatic sinus, owing to tumefaction of the surrounding tissues. In a man who has even very slight general enlargement, or the beginning of centric hypertrophy of the prostate, with a "third

lobe" so small as to cause no obstruction, an exposure to cold, or over-indulgence in the pleasures of the table, or in venery, will cause sudden engorgement of the pelvic vessels, which will give rise to such increase in bulk of the whole prostate, partly by serous infiltration, as to completely close the urethro-vesical orifice, and of course to retention of urine. And you may ask why should sudden increase of the prostate cause obstruction to the flow of urine, when it is known that many patients who have enormous prostates are able not only to urinate but to empty their bladders? I answer that there is a very great difference between sudden engorgement and chronic enlargement. In the former the resisting fibrous capsule of the prostate will not yield to sudden pressure, and the consequence is that the third lobe, "being unprotected by the capsule and free at its summit, rapidly swells; the sides of the prostatic sinus are likewise tumefied, and the urethro-vesical orifice and prostatic urethra are finally thus blocked up, and this is usually the work of a few hours, as it is for example in œdema of the glottis; whereas in the latter, the slow hypertrophic process permits the capsule gradually, month after month or year after year, to accommodate itself to the steadily increasing gland, leaving room for the escape of urine. I scarcely need tell you that those very patients with great general hypertrophy of the prostate, who ordinarily empty their bladders without artificial means, are extremely liable to acute retention of urine from the same causes as the others, and that often after this accident the obstruction is not removed, and they are never again able to pass urine without the aid of a catheter. The patient who is now before you is a good example of this variety of cases.

The symptoms and progress of acute retention of urine are: for an hour or two, dysuria, the first efforts at urination giving issue to short jets of urine which cause such severe scalding, burning pains in the deep urethra, that the patient instinctively represses the flow; then follows strangury, with the escape, at times, of drops of blood or bloody mucus, alternating with the drops of urine; this may continue also an hour or two; and at last comes ischuria, or inability to discharge a single drop of urine in spite of the violent straining efforts which will often cause the escape of feces, or even prolapse of the rectum. If the case be left to itself, the urine will accumulate until the bladder bursts or becomes atonic and distended to the point of containing six or eight pints or even more, when urine will begin to dribble away involuntarily. During these distressing stages of the complaint there is great general neurosis, much agitation, marked febrile reaction, thirst, facial congestion, accumulation of gas in the intestines, much pain, with an almost insupportable sense of distention in the hypogastric and lumbar regions, dryness of the skin, then profuse perspiration with urinous odor, muttering delirium, oliguria, then anuria or complete suppression of urine, and if the patient does not die in consequence, polyuria is very apt to follow.

During the first twenty-four hours the patient suffers the greatest torture from increasing distention of the bladder, and from constant, irrepressible straining. So far, the accumulation may not have exceeded three pints, but in the meantime the poor sufferer has taken a little of everything that may have been suggested—nauseous decoctions of all sorts, diuretics innumerable—all serving only to increase his troubles. Suppose the case to occur in the country, and the wretched patient to be in the hands of the old women of the neighborhood. After every imagin-

able local application has been suggested, and several of the most filthy tried, they begin with teas: linseed, slippery elm, comfrey, etc., with a liberal allowance of nitre in each cup; but all these potions have failed, when finally, at the expiration of forty-eight hours, in comes an old friend with a bottle of gin which he boldly asserts never fails to cure all his own ailments. He speaks so confidently of the wonderful effects of his panacea in urinary troubles, and of its general harmlessness, that the patient, now in utter despair and ready to grasp at any straw for relief, consents to take a gin julep. It is nearly time, as you know, for the beginning of dribbling from overflow, and for the pain and straining to lessen; in other words, for the bladder to lose its contractile power. Within an hour, while he is waiting for the effect of this never-failing remedy, the urine has begun to flow drop by drop. He could not have selected a more favorable moment for the display of his wisdom, as on the first day he would have been sadly disappointed. Now imagine the triumphant air, attitude, and gesture of the prescriber, when he exclaims, "I told you that the gin would do it, never has it been known to fail!" . . . All of course concur with him in ascribing this marvellous result to the drink of gin, and insist that the patient shall take more, and he does take more. The urine flows continuously, in very small quantity for hours, but by and by some one suggests that the patient is making too much water, and that means must be taken to repress the flow. How to accomplish this none can tell; so they decide to consult a doctor, who is at length sent for to stop this constant and, as it is thought, injurious flow of urine. The doctor comes promptly, learns what has been done, inspects the abdomen, makes percussion, finds the bladder greatly distended, at once introduces a catheter, and to the amazement of the bystanders draws off slowly, in the course of two hours, three or four pints of urine, withdraws the instrument, and makes the startling statement that he has only half emptied the bladder.

You will occasionally be called to precisely such cases, and I hope you will do precisely what the doctor has done. You will forthwith proceed to remove slowly and gradually only a part of the contents of the bladder.

Why forthwith? Because to temporize in such cases is criminal stupidity; it is worthy of the senseless and meddlesome neighbors, who are to be found everywhere, and who are usually the enemies of truth, reason, and common sense. However, they are not the only people who have been known to temporize in cases of retention of urine. In this very city of New York, how often, not many years ago, certain medical men treated cases of acute retention of urine by embrocations, hip-baths, diuretics, and especially free doses of tincture of the chloride of iron, for days, when the catheter would have done the work so promptly and effectually. One of the believers in this expectant treatment, who was asked why he would not use the catheter, said it was because the tincture of iron "always *in time* makes them urinate." This sort of management, I repeat, which excludes the catheter when its use is so clearly indicated, is worse than stupid, it is criminal.

Why should you withdraw only a part of the urine from an over-distended bladder? Why slowly and gradually? Because experience has taught careful observers that when the contents of a largely distended cavity in the body are suddenly evacuated, the consequences are usually hurtful. For instance, in tapping for ordinary abdominal dropsy, neglect

during the operation to use compression with a proper bandage, or the too precipitate withdrawal of the serum, has been followed by the most untoward results, such as syncope, hemorrhage in the peritoneal cavity, and even fatal peritonitis. Profuse hemorrhage also sometimes follows the sudden emptying of large abscesses, of thyroid and other cysts, and of those long-neglected enormous hydroceles of the tunica vaginalis testis. The same almost always occurs when a greatly distended bladder (in an elderly man) is completely relieved of its contents with too much precipitation. Let me now give you what I conceive to be the correct explanation of such a hemorrhage in the bladder. So long as the bladder remains distended there is no bleeding; but as soon as the urine is drawn hemorrhage begins. The vesical parietes, from having been in a state of extreme tension, in an instant become flaccid, the capillaries of the mucous membrane, from having been greatly stretched and almost emptied, are suddenly gorged with blood, and being deprived of the hydraulic support of the urine which but a moment before braced them up, their delicate walls, unable to resist the increased internal pressure exerted by the circulating blood, give way, and the blood oozes from thousands of little rents on the surface of the vesical mucous membrane. These vesical hemorrhages are often abundant, and have been known to last two and three weeks, but they very seldom prove fatal directly, that is, from the amount of blood lost; the danger lies mainly in the consecutive general cystitis which cannot always be controlled. A septuagenarian suffering from prostatic hypertrophy died from this cause several years ago. The patient had acute retention of urine, with great distention of the bladder, which was suddenly emptied with the aid of a catheter introduced by his surgeon. Within a few hours the bladder was again distended, this time not with clear urine but mainly with blood. Each subsequent catheterism brought a great amount of blood, and the old gentleman grew gradually worse, with symptoms of acute general cystitis, and died within ten days.

About four years ago I saw, in consultation, a similar case, which however terminated favorably. The patient was 63 years of age, and had some prostatic hypertrophy, but had not been obliged to use the catheter. He was, on the morning after an exposure to cold, seized with acute retention of urine, which he had had on several former occasions, and after some delay summoned his physician, who at once introduced a catheter and withdrew three pints of clear urine. A second catheterism on the same day gave issue to bloody urine, and from that time all the urine drawn off was highly charged with blood, clots of which at times became impacted in the catheter. I saw the patient nine days after the first catheterism, and drew off a pint and a half of fetid, thick, alkaline, tarry fluid, consisting of about an equal amount of blood and urine. The catheter was left in for twenty-four hours and the bladder thoroughly drained, while an occasional irrigation with an astringent solution was used. Afterwards the urine was drawn off every three hours and the bladder duly irrigated. No more hemorrhage occurred after complete drainage was effected, and the cystitis was easily managed.

A safe rule, therefore, for your guidance in the management of cases of acute retention of urine of forty-eight hours' duration, is never to draw off more than one-third of the contents of the bladder, and to do this very slowly by half closing the distal end of

the catheter, so that the urine will flow in a very small stream. Having collected half a pint, close the catheter for a quarter of an hour, then let another half-pint flow, and so on, until the required quantity has been obtained. In two hours repeat the catheterism if the first has been easy—otherwise the catheter should be closed, and left in for twenty-four hours—and remove again the same quantity very gradually, and at the expiration of another period of two hours you may completely empty the bladder, always slowly; and in this way you will have taken the necessary precautions to avoid both cystorrhagia and polyuria. Every three hours after the last catheterism the urine should be drawn off until the patient can pass it spontaneously; if he cannot do so, of course the catheter will have to be resorted to at such intervals as may be found necessary. You will also have to treat the existing vesical inflammation and atony. For general medication I would recommend the tincture of chloride of iron in five-minim doses three times daily, and also diluent drinks, such as thirty grains of citrate of soda or potash in half a glass of water three times daily, and in a few days, for a change, dog-grass tea, etc. Topically, lumps of ice the size of the last joint of the thumb should be introduced into the rectum in rapid succession as fast as they melt, for an hour night and morning. A bag of ice may be afterwards applied alternately to the perinæum and hypogastrium for an hour or more. Each time the bladder is emptied by the catheter, a couple of ounces of cold borax solution, from five to ten grains to the ounce, should be thrown in and allowed to run out slowly, then two more, and two more ounces which should be left in and the catheter withdrawn; this can be accomplished in five minutes. No preparation gives me more satisfaction than the borax solution for cleansing bladders which contain offensive purulent urine. It is as well to have in readiness a strong solution of borax in glycerine; one ounce of the bichlorate of soda will be readily dissolved by six ounces of glycerine, each drachm of such a solution being equal to ten grains of bichlorate. In a week or thereabouts, if the case should progress well, the irrigations may be diminished in number until only one is used each day. In some cases a mild faradic current is serviceable.

Besides hemorrhage, polyuria, as I have already said, is very apt to follow the sudden evacuation of an overdistended bladder, and you will generally prevent its occurrence by observing the caution that has just been given. I know of a case of polyuria which followed the withdrawal of three pints of urine in the course of one hour, one pint at a time, the third pint completely emptying the bladder. The catheter was left in, and every hour for twenty-seven consecutive hours one pint of urine was drawn. After this the amount of urine gradually diminished, until only six pints were removed each twenty-four hours. At the end of three months it was reduced to four pints daily.

The case just cited is exceptional, for ordinarily it is safe to empty the bladder—slowly of course—at one catheterism, when the patient is seen during the first twenty-four hours of an attack of acute retention.

RETENTION OF URINE IN CASES OF CONTRACTED BLADDER.

Let me now, in a few words, direct your attention to those cases in which there is chronic cystitis with diminished capacity of the bladder, and in which the accumulation of even four ounces constitutes retention

of urine with its most distressing symptoms. A patient suffering from chronic cystitis, who for a long time has been obliged to urinate every hour, half-hour, or even more frequently, is suddenly unable to relieve himself. For the next two or three hours he is in the most intense pain, and in the condition of an ordinary case of acute retention of twenty-four hours' standing.

A catheter is introduced, and any young surgeon unacquainted with like cases will be surprised that only four or five ounces of urine have come away, but the patient experiences quite as much relief as another from whom two or three pints of urine may have been drawn. The early recognition of the nature of such cases will be to you of the utmost importance, and their management will require your best skill and judgment. The catheter should be used promptly and with the same care as in the other cases, but more frequently, especially when cystorrhagia or polyuria supervenes, as the pain and vesical spasms may be such as to forbid the retention of the instrument beyond a few minutes.

THE HISTORY OF MASSAGE.*

By DOUGLAS GRAHAM, M.D.,

BOSTON, MASS.

PART II.

The third historical division of massage, or what is found recorded about it in more recent times, has been styled its period of improvement. To Peter Henrik Ling, of Sweden, is given the credit of having instituted, in 1813, what is so well known as the "Swedish Movement Cure." Some even regard him as the inventor of this system of treating certain diseases, while others consider that he only made rational that which had been in practice for many centuries among the Chinese and other eastern nations. The latter is the more correct view, and the one which Ling himself doubtless held; for Dr. Roth, a disciple of his, states that Ling thought not, like his predecessors, of merely imitating the gymnastic treatment of the ancients, but he aimed at its reformation and improvement. From the following remarks of M. Georgii, one of Ling's pupils, it has been thought by M. Estradère (Du Massage, 1863) that Ling claimed to have invented the movement and manipulation treatment of disease. "Let us speak of the series of movements invented and determined by Ling. Here the influence comes solely from without, and the patient submits to the mechanical impression. Ling means by passive movements all communicated movements, such as pressures, frictions, percussions, *frottement* (manipulation of the skin and subcutaneous cellular tissue), etc., motions and attitudes suitable to produce temporary or artificial congestion in an organ." Hereafter Estradère disputes somewhat bitterly the honor thus given to Ling, and adduces abundant and interesting testimony to show that "Ling's entire system was but a compilation of all the exercises, frictions, and manipulations which had been practised before him among many nations. The method of Ling is that of the Brahmins of India; it is that of the

* Concluded from page 156.

Egyptian priests; it is that of Asclepiades, of Pythagoras and of Herodius, one of the masters of Hippocrates; it is that of which Hippocrates, Celsus, Galen, Rufus of Ephesus, and other physicians, Greek and Roman, have preserved fragments for us. All the movements which Ling has indicated are described in the *Cong-Fou* of the *Tao-Ssé*." However the genius of Ling, and the claims of priority made for him, may have been disputed, there seems to be no doubt as to the merits of the system which he rescued from oblivion, and to all accounts put upon a scientific basis. "In the rooms of the central establishment at Stockholm persons of every condition and age, the healthy as well as the sick, executed or were subject to the prescribed movements. The number of those who adopted the use of the therapeutic movements increased every year, and among them were even physicians who, in the beginning, had been the most opposed to Ling." In 1844 the Supreme Medical Board of Russia appointed two members of the Medical Council to inquire into the merits of the movement and manipulation treatment as practised by M. de Ron, one of Ling's disciples, at St. Petersburg. He had then been using it there for a period of twelve years, and from the highly commendatory report of the Councillors we quote the following:

"All passive movements (those which are executed by an external agent upon the patient), as well as active ones (produced by the effort of the voluntary muscles), and the different positions, with the aid of apparatus or without it, are practised according to a strictly defined method, and conducted rationally, since they are based upon mechanical as well as anatomical and physiological principles. *Experience teaches us the usefulness of the institution, as many persons thus treated have recovered their health after having suffered from diseases which could not be cured by the ordinary remedies.* We must also mention the testimony of Dr. Bogoslawsky, who himself, after having been cured in that institution of a chronic disease, has practised diligently these movements (including friction, manipulation, etc.), and who, being appointed consulting physician to that institution, has since then had opportunities enough of observing and witnessing numerous cures."*

In Sir John Sinclair's Code of Health and Longevity we are told that Admiral Henry cured himself of rheumatism by means of friction and percussion with instruments made of bone polished smooth, cork hammers, and the bottom ends of glass vials. He was at that time, 1810, seventy-nine years of age, and had suffered from rheumatism for twenty-eight years. There were swellings in his knees, ankles, and insteps which made him quite a cripple, so that he could only crawl about. He persevered in the frictions and percussions night and morning for three years, at the end of which, it is said, he had completely succeeded in removing the swellings, and had restored himself to the use of his limbs. The fingers of one hand were swollen and contracted, it was thought from gout, but by the persistent use of his instruments they became quite flexible. Many of these operations of deep rubbing and percussing the admiral described as being at first painful; but they ceased to be so after having been persevered in for a little while, and became even pleasant and so useful that, after having gone through with them in the morning, he felt better all day. "If regularly done for some time," says the admiral, "the muscles become so sound and firm that neither pinching nor beating with violence gives any

pain, while with the improvement of the frame the mind becomes stronger, the spirits improve, and the faculties are strengthened."

In 1782 a cataract began to form in Admiral Henry's left eye. He was accidentally led to try rubbing in a peculiar way, with the result, it is stated, that in less than two years the cataract was dispersed. Two years later a cataract came in his right eye, and this he was persuaded to have removed more quickly than the other had been. It was operated upon by a distinguished oculist of London, in 1799, and he lost the sight of it, so that, had it not been for the successful dispersion of the cataract in the left eye, the admiral was sure he would have been entirely blind.* After the cataract operation the admiral suffered from excruciating facial neuralgia for a year, which reduced him to a state of great weakness. Having used various remedies with but temporary relief, he then tried deep rubbing with his instruments, and thus, it is said, completely removed the complaint. He kept up his frictions and percussion as a means of preserving his health, and the result was that at the age of ninety-one he enjoyed the activity of middle life, and had attained to as good a state of health as any man in England. In a letter to a friend, dated March 1, 1823, he writes: "I never was better, and at present am likely to continue so. I step up and down stairs with an ease which surprises myself. My digestion is excellent, and every food agrees with me. I can walk three miles without stopping."

The admiral's system of massage was rather rough, and probably nothing would have inspired him with such perseverance but the enthusiasm arising from the firm belief that he had discovered and invented a new system of treatment. What he observed with regard to his procedures being at first painful, but subsequently becoming agreeable, is very true, and has been often noticed by others in a variety of cases more recently, some even intimating that in this they have made an observation hitherto unknown. It is difficult for some people to imagine that *matted*, rigid, and painful tissues can become of natural suppleness, elasticity and feeling, under the use of massage; as well as the fact that flabby, over-sensitive tissues deficient in size, tone and firmness can often be made, by means of massage, to assimilate the nourishment necessary to their proper formation. On this subject let old Celsus again speak. "For a thing becomes constricted when we take away that which by its interposition produced relaxation, and softened when we remove that which caused its hardness, and filled, not

* Other cases of a similar kind might be quoted, but it must not be forgotten that cataracts sometimes improve for a time, and they have even been known to disappear of their own accord. Dr. Pagenstecher, of Wiesbaden, a trustworthy oculist, has used massage in two cases of episcleleritis, and one of parenchymatous keratitis, with "such favorable results that he no longer hesitates to report them." Of the rapidity of improvement, he says he has "never observed the like with other methods of treatment;" and, however his further attempts may turn out, "still the significant fact remains that one can by means of massage diminish the intraocular pressure in suitable cases.—*Centralblatt für Prakt. Augenheilkunde*, Dec., 1878.

I have used massage of the head and locally with marked and permanent improvement in three cases of muscular asthenopia: one a myopic patient, one a hypermetropic—both of whom had had their refraction long before attended to—and one an emmetropic patient. This is not the place to speak of the tangible changes which occurred in the accessible tissues, and which coincided with, or even preceded improvement in these cases; nor is there room to speak of the manner of using the massage, which was not by superficial friction, as is generally supposed. Nor yet is there space to discuss the rationale; but it may be pardonable to suggest that if there may and does arise a dozen different affections of the eye from cold, exciting a neuralgia of the infra- or supra-orbital nerve (see *Arch. de Médecine*, July, Sept., and Nov., 1854, and Brown-Séquard's Lectures on Functional Nervous Disorders, 1858), why is it not reasonable to expect improvement in as many maladies of the eye from the use of massage, which acts in a reverse manner from cold, but through the medium of the same tissues—provided the affection is not beyond recovery? D. G.

by the rubbing, but by the food which afterward penetrates to the skin which has been relaxed by a kind of digestion or removal of its tissue."

A curious old book is that entitled: "A Full Account of the System of Friction, as adopted and pursued with the greatest Success in Cases of Contracted Joints and Lameness from various Causes, by the late eminent Surgeon, John Grosvenor, Esq., of Oxford." About a century ago Dr. Grosvenor was professor of surgery for many years at Oxford. His skill and reputation became so great that he was soon in possession of all the surgical practice at Oxford, and on every side of it within a radius of thirty miles. "He practised simply as a surgeon, in the proper and strict sense of the word; and while he never condescended to soil his fingers with the preparations of pharmacy, he constantly refused at the same time to invade the province of the physician. In the latter period of his practice, Mr. Grosvenor rendered himself justly celebrated throughout the kingdom by the application of friction to lameness or imperfections of motion arising from stiff or diseased joints. He had first used it with success in a complaint of his own, a morbid affection of the knee; and by degrees its efficacy was so acknowledged that he was visited by patients from the most distant parts, of the highest rank and respectability—among others, by Mr. Hey, the able surgeon of Leeds. Those who have benefited by the process pursued under his own immediate superintendence in cases of this sort, and from total inability have been restored to a free use of their limbs, are best able to attest his merits. That he was scarcely in any instance known to fail was perhaps attributable to the circumstance that he used his utmost efforts to dissuade from coming to Oxford to try the experiment every one of whose case, from previous communications, he entertained any doubt. Possessed at this time of affluence, he became very indifferent about business, and, at a time of life when he was still capable of active exertions and his strength was but little impaired, he began to contract his practice. For the last ten years of his life he had wholly given up his profession, except in the instances of his rubbing patients."

It may be worth while to mention the cases in which Mr. Grosvenor found massage most serviceable, inasmuch as its value in similar cases has since been confirmed by others. "First, contractions of the joints, unattended with inflammatory symptoms, proceeding from cold, dampness, or rheumatism, attended with languid circulation, and thickening of the ligaments. Secondly, in those cases where there is too great secretion of the synovial fluid, particularly in the knee-joint. Thirdly, after wounds in ligamentous, tendinous or muscular parts, where the function of the limb or part is impaired; but here it should not be made use of till the inflammation and tenderness have subsided. Fourthly, in cases of paralysis. Fifthly, those of chorea, combined with attention to the system. Sixthly, Violent strains of joints, when the inflammatory symptoms have entirely subsided.* Seventhly, in

* Inflammation does not, by any means, contraindicate the use of massage in such cases, for, in the words of Berghmann and Hellebly, "massage will simultaneously further and increase resorption, accelerate the circulation, relieve pain, and reduce elevated temperature." If any one wants to look into this matter, they will find in my report on the treatment of sprains by massage (in the New York Medical Record, No. 353, 1877) the results of this method in 312 cases by ten different observers, independently of one another. Though the inflammatory symptoms in many of these cases were severe, yet the result of the use of massage in all showed that they recovered, or were cured, in one-third of the time required for similar cases treated in the usual methods alone. But no surgeon will believe this unless he has tried it for himself, or been treated in this manner for a sprain in one of his own joints.—D. G.

incipient cases of white swelling this is almost the only remedy that has been found effectual, and it has frequently happened that joints absolutely condemned to the knife, and on the point of being amputated, have been saved and their use restored by this method. After fractures of the articulating extremities of the joints, as when the bones are united, a stiffness generally remains. In all the various dislocations of the joints, when the motion of the joint is left impaired, after the inflammation has subsided. After ruptures of tendinous or ligamentous parts, provided they are firmly united."

Another " quaint and curious volume of forgotten lore," is that of "Illustrations of the Power of Compression and Percussion in the Cure of Rheumatism, Gout and Debility of the Extremities, and in Promoting Health and Longevity. By Wm. Balfour, M.D., Edinburgh, 1819." Dr. Balfour claimed for himself the originality accredited to Dr. Grosvenor by his friends, viz., that of discovering a new method of treatment, without inquiring if there were any previous data to start from. This fact, however, makes their testimony all the more valuable and unbiassed, which we can doubtless trust, for they were eminent practitioners in their day, and any one who reads their books would certainly say honest as well. Dr. Balfour's book is mainly made up of reports of cases of rheumatism, gout, neuralgia, sprains, and the results of injuries treated by means of percussion, deep rubbing, and firm compression with bandages. The cases are well reported, and are interspersed with forcible and philosophical remarks. Those who revived tight strapping in sprains a few years ago would have done well to have first looked into old Balfour. The following from the introductory chapter is a specimen of how the doctor regarded those of his professional brethren who did not adopt his views so readily as he thought they should have done. "Medical practitioners encourage their patients in giving perfect rest to parts affected with rheumatism and gout, till, as often happens in the latter disease, the vessels change their actions altogether. It is incumbent on such practitioners to show that there is greater security to life in painful, rigid, and swollen limbs, and in frequent and long confinement, than in the free and equable circulation of the blood through every part of the body and in exercise in the open air. It is incumbent on them to show that life is more secure when the functions of the body are imperfectly than when duly performed. . . . It was observed by Lord Bacon that knowledge more quickly springs from absolute ignorance than from error. It is much easier, surely, to instruct the ignorant than to convince the prejudiced. But, in spite of the hostility that has been shown to the practice illustrated in the following pages, I have the satisfaction to see it adopted at last by physicians of the first eminence.* It may with truth be affirmed that there never was an important improvement made in the practice of medicine yet but what met with opposition. Mercury, bark, cold affusions in fever, vaccination, all experienced it. Nay, Harvey himself lost his practice on account of discovering the circulation of the blood."

From his own extensive general practice, Dr. Balfour selected cases for his new method of treatment. Many of these, from a state of chronic invalidism, improved rapidly and got well, and there were but few who did not receive some benefit. His remarks on the effects of percussion have not yet been excelled; nothing in the recent German reports on

* Vide Transactions of the College of Physicians, Dublin, vol. 1.

massage equals them. Says he: "Whoever has the slightest acquaintance with natural philosophy and chemistry knows that percussion produces wonderful effects on inanimate bodies. A mason will cut a stone of immense thickness perpendicularly through by a few strokes of a hammer. A few strokes of a hammer will drive home a nail on which an immense weight gradually applied would have little or no effect. A smith's anvil may be made hot by continued and forcible hammering. Is it surprising, then, that a power which produces such wonderful effects on inanimate matter should exert a powerful influence on the living body? If I apply percussion in the course of the sciatic nerve of a person laboring under sciatic rheumatism, a pleasurable vibration will be communicated through the whole limb, the nervous power being thereby diffused. If I apply percussion to a paralyzed limb, I thereby attract to it the nervous energy. If I apply percussion to limbs debilitated by rheumatism, gout, or old age, I thereby excite the action of the vessels and nerves, promote the circulation, and restore that heat of which they are deprived through inactivity and the weakness of the powers of life."*

A paragraph from Estradere will indicate sufficiently the state of massage in France in 1863, and, so far as I can learn, at the present time also: "Although numerous observations upon the benefits of massage in certain affections have been communicated to the Academy of Sciences and other learned societies; although some physicians became alarmed at the enormous practice of an empiric, Moltenot, who massaged at Orleans in 1833, and entreated the Court of Justice for a sentence against him; although Récamier and his pupils, Séguin and Maisonneuve, had lectured upon massage before all the learned societies; although in these times the most distinguished physicians of Paris very often prescribe massage; yet, for all that, it is still under the domain of empiricism, because physicians are content with indicating its therapeutical results, without interrogating anatomy and physiology for the reasons of these results. Nevertheless, this age has a tendency toward improvement in this matter, and already the physiologists have given some satisfactory explanations of the effects of massage, passive and mixed movements."

About seven years ago Dr. Mezger, of Amsterdam, treated the then Danish crown prince successfully for a chronic joint malady by means of massage, which he used in a manner original to himself, and in accordance with the teachings of physiology and pathological anatomy. When the prince got well he sent a young physician to Amsterdam to study Dr. Mezger's method of applying it, and soon after many old as well as young physicians visited the clinic of Mezger, and they all agreed that the so-called massage, used in Mezger's manner and according to the indications which a very large experience has enabled him to point out, is a most worthy agent in various affections of the joints, besides in inflammations and neuroses. They consider that credit is due to Mezger for having improved massage in a physiological manner, and for having brought it to be acknowledged as a highly valuable method.

A few extracts from the very excellent and compre-

hensive report on massage, in *Schmidt's Jahrbücher*, Vol. 166, 1875, will show the estimation in which it is held by some of the first German physicians. The reporter begins by saying that "it is but recently that massage has gained an extensive scientific consideration, for it has passed out of the hands of rough empirics into those of scientific, cultivated physicians; and, upon the ground of the results of recent scientific investigation, it has been cultivated into an improved therapeutical system. The Danish physician, Mezger, has won the merit of having made massage in its entirety a special branch of the art of medicine." Then follows a list of forty articles on massage, by a score of authors, mostly Scandinavian, only one being American. The manner of using massage and its physiological action are next described; and, after this, the results of massage in similar cases, treated by different authors, are grouped together and compared—so many cured, so many benefited, and so many not relieved. The report concludes by saying that, "if massage is to be of any use, it ought to be applied by those who are absolutely physicians; for the brilliant results which have just been cited depended upon an exact knowledge of anatomy and physiology, and also upon recent progress in medical and surgical pathology, which enabled the operators to make an accurate diagnosis. A very important part of the qualifications necessary for the effectual performance of massage depends upon the physical qualities of the manipulators; they require strength of hands and fingers, endurance and elasticity, which every physician does not possess; and herein lies the danger that the practice of massage will pass into the hands of the laity, who, again, have not the other requisites, viz., medical knowledge."*

It would not be doing justice to this brief historical sketch of massage to omit the description of *lomi-lomi* given by Nordhoff in his "Northern California, Oregon, and the Sandwich Islands," 1874. "Wherever you stop, for lunch or for the night, if there are native people near, you will be greatly refreshed by the application of *lomi-lomi*. Almost everywhere you will find some one skilled in this peculiar, and, to tired muscles, delightful and refreshing treatment. To be *lomi-lomied* you lie down upon a mat, or undress for the night, if you prefer. The less clothing you have on, the more perfectly the operation can be performed. To you thereupon comes a stout native with soft fleshy hands, but a strong grip, and beginning with your head and working down slowly over the whole body, seizes and squeezes with a quite peculiar art every tired muscle, working and kneading with indefatigable patience, until in half an hour, whereas you were weary and worn out, you find yourself fresh, all soreness and weariness absolutely and entirely gone, and mind and body soothed to a healthful and refreshing sleep. The *lomi-lomi* is used not only by the natives, but among almost all the foreign residents; and not merely to procure relief from weariness consequent on over-exertion, but to cure headaches, to relieve the aching of neuralgic or rheumatic pains, and by the luxurious as one of the pleasures of life. I have known it to relieve violent headache in a very short time. The chiefs used to keep

* Percussion can be performed in half a dozen different ways with the hands and fingers, varying in force and rapidity. I have recently had two india-rubber air-balls, securely fastened on the ends of whalebone handles, for this purpose. Balls 2 in. diameter, and handles 11 in. long, are most suitable. They work most admirably, as one gets the spring of the whalebone with the rebound of the balls, thus gaining great rapidity of motion, with easily varying intensity. It takes considerable practice to become expert in using them.

* Prof. Von Mosengeil, of Bonn, speaking of massage, says: "Its value must be recognized; but it is not adapted for every-day use by every physician; nor will it be much used in hospitals, for lack of time. The best results will be obtained by the few who bring to its use abundance of time, patience, skill, and strength. Specialists, therefore, will probably get the most satisfactory results from it. (Arch. f. klin. Chirurg., XIX., 4. 1876.)—D. G.

skilful *lomi-lomi* men and women in their retinues; and the late king, who was for some years too stout to take exercise, and was yet a gross feeder, had himself *lomi-lomied* after every meal as a means of helping his digestion. It is a device for relieving pain and weariness which seems to have no injurious reaction and no drawback but one—it is said to fatten the subjects of it."

Though massage in some form or other is in all probability a primitive institution among all nations, yet the word skilful is not used amiss here by Nordhoff; for some people have a natural tact, with a peculiar quality of strength and structure of hands, which render them vastly superior as manipulators. Add to these the improvement acquired by long practice, and the enlightened experience which a medical education alone can lead to, and we have such a person to use massage as those only will appreciate who have had less favored manipulators apply it to them. It is a pity that there are not more epicures in this matter, who would willingly place the different operators in massage on their merits, irrespective of the policy of others in employing ignorant and incompetent rubbers. There are as great variations in hands for massage as there are in voices for singing. A person who has a naturally charming voice well cultivated is estimated very highly; a person who has by practice and education cultivated the use of a pair of hands excellently adapted for massage, probably never will be estimated so highly or rewarded so richly, but the efficient work which they can do is second to no other of a different kind, and it is as soothing, charming, and beneficial to many invalids as sweet music is to those who are harassed with the corroding cares of life.

"*Lomi-lomi* is said to fatten the subjects of it" (by stimulating the nutritive processes). This, with the above remarks about the late king of the Sandwich Islands, might easily have furnished an indication to the purpose for which massage was used in the class of cases described in the very interesting little book entitled "Fat and Blood, and How to Make Them," which was not published until three years after Nordhoff's book—sufficient time to give the suggestion a trial. The author of "Fat and Blood," in the chapter on massage, says he has some facts to relate with regard to it which, he thinks, are not known on either side of the Atlantic. In view of this statement, these facts ought to be of great value. What are they? and what is the author's own estimate of them? Evidently they are the changes of temperature produced by massage. "These facts are, of course, extremely interesting," says Dr. Mitchell, but it is well to observe that the success of the treatment is not indicated in any constant way by the thermal changes, which are neither so steady nor so remarkable as those caused by electricity." The reviewer of "Fat and Blood," in the *American Journal of the Medical Sciences*, January, 1878, attaches a great deal more importance to these changes than the author himself does; says he: "Although it has been noted by Trousseau that the increased warmth of the skin produced by massage is due to the more active cutaneous circulation, it is reserved to Dr. Mitchell to put this point on an exact scientific basis by a series of accurate thermometric observations." If the success of the treatment is not indicated by these changes, of what value are they as a scientific basis? It is not very clear that they have any relation to a scientific basis at all in the class of cases referred to, for, by the author's own confession, they may, to all intents and purposes, be disregarded so far as any utility is concerned.

MILK WITH LIME-WATER IN SCROFULOSIS.

By E. N. CHAPMAN, M.D.,

ROCHESTER, N. Y.

CORRESPONDING MEMBER OF THE SOCIÉTÉ MÉDICO-PÉRIODIQUE DE PARIS.

THERE is a large proportion of children in every community whose vitality is below the normal average. They sicken on slight provocation, respond poorly to remedies, and, before the cure is attained, succumb to some new ailment. Exciting causes that would be inoperative in a well-balanced constitution meet with feeble resistance, and disorders that nature should successfully combat linger in an atonic form, in spite of the care of the mother and the skill of the physician. Morbid action extends from point to point, implicates the most diverse structures until, eventually, the whole organism seems involved in a general revolt against those laws, the harmonious operation of which constitutes health. The digestion is retarded, the assimilation imperfect, and the blood depraved; the nerves are irritable, the secretions defective, and the excretions insufficient. The repair and waste are not in accord; the new and the old materials load the circulation, and the several processes by which food is worked up into vitalized, and thrown off in devitalized products, are slowly and imperfectly accomplished. As a necessary result, every member of the body is prone to many forms of disease, usually of the inflammatory type, which, however active it may appear, is always of a low grade, and never bears a reducing course of medication.

In a strumous person there is a defect at every stage of that preparation by which the food is converted into the living organism. The machinery having been poorly constructed, the work is of course poorly done. What is worse, the fault is usually inherent, and dates back to a hereditary taint, developed in the ancestral line years before the subject saw the light.

To overcome this vice, and institute a new order of things, the attempt is made to supplement the defects of digestion by adding to the diet, and to correct the error of assimilation by administering drugs. A bitter is given to excite the appetite; pepsin, to aid the stomach; pancreatine, to emulsify the fat; meat, to make muscle; phosphorus, to nourish the brain; iron, to color the blood; and oil, to impart heat. All this while, as the indications seem to require, the phosphates, iodine, cod-liver oil, etc., are employed to revolutionize the system, and bring order out of disorder.

These means, even when aided by the most favorable hygienic influences, are rarely of more than temporary advantage. The evil, suppressed but not conquered by the resources of art, soon rises in rebellion, reasserts its supremacy, and reduces the organic forces into subjection. The support being taken away, and the economy thrown upon its own resources, the various functions give way, fall into disorder, and leave the way open to the old enemy. In a word, this course demands constant surveillance, always secures a seeming advantage, but never wins a lasting victory.

The trouble in scrofulosis is not a deficiency of nutritious elements in the food, but a lack of preparation for absorption and assimilation. There is an abundance of albumen, sugar, oil, phosphorus, iron, and lime, and yet these constituents, so essential to health, do not reach the blood in a state fitted to meet the wants of the system. Besides, no inconsiderable

portion, being but imperfectly acted upon by the gastro-intestinal secretions, passes off in the feces. As a consequence, the blood is starved and the constitutional force reduced to a low ebb. In a healthy person, on the contrary, all these elements are extracted from the food and appropriated by the system. They are never needed as medicinal agents. This source is the proper one—the one always offering an abundance, and that of the best. An artificial supply can accomplish nothing more than the natural, unless means are first instituted to improve the digestive processes, as both must undergo the like changes before they can gain an entrance into the lacteals. Otherwise, the digestion will be more oppressed and the blood more deteriorated.

The true plan is not to give more and richer, but less and simpler food; not to increase, but to lessen the work of the stomach; not to attempt an artificial, but to restore the natural digestion; and not to depend upon drugs, but to regulate the diet. Fortunately, milk answers every requirement and is better than anything else, as it is capable of filling the place of both food and medicine in many grave emergencies. It is the only nourishment at the earliest period in the life of the mammalia; it contains all the elements of nutrition in the proportions needed to build up and sustain the animal frame; and it is the most digestible of all articles, when the casein has been rendered soft and flocculent by the addition of lime-water. Imposing little labor on the stomach, the milk restores its tone; prepares the way for other food; offers a better chyle to the lacteals; renovates the blood with new material, and nourishes every part with the albumen, oil, phosphorus, iron, lime, etc., needed to renew its energy and restore its integrity. In a word, the milk meets every indication in alimentation and medication.

LYMPHATIC GLANDS.

When scrofulosis manifests itself in a mass of enlarged, indurated glands that eventually suppurate, it is seldom possible to disperse them and eradicate all traces of their previous existence, save the white line left in the track of the knife. Meat fails to give strength, iron to make blood, quinine to brace the nerves, phosphorus to feed the brain, and iodine to correct the constitutional depravity. Wine, air, exercise, recreation, travel, and the many other agencies invoked with such signal advantage in most chronic disorders, are here important. Indeed, all accepted dietetic, therapeutic, and hygienic means, seem rather to clog the wheels of the vital mechanism, or at least to impart no permanent force to that already present. The faulty nutrition goes on, and declares itself at various times and in various ways until the advent of puberty, when the completion of the growth lessens the drain on the nutritive fluids, and allows nature to husband her slender stores.

Some four and a half years since a poor woman brought a son of hers, about seventeen years of age, to my office. He was markedly strumous; had always lacked blood, nerve, muscle, and force, and now presented a chain of glands on the right side of the neck that extended along the line of the sterno-cleido-mastoid muscle. These glands, much enlarged and intensely inflamed, soon suppurated, and were lanced. Holding an out-door position in an insurance company, the boy had been obliged to do a good deal of walking. This, together with a poor diet, seemed to have exhausted his nervous energy, and precipitated this greater manifestation of scrofulosis.

The glands, when they had fully matured by the

aid of poultices, were lanced, and then, while they continued prominent, were painted with the tincture of iodine. Rest and quiet were enjoined for a couple of weeks, and iron and quinine administered alternately for some two or three months. The main thing, however, was the regulation of the diet so as to adapt it to a weak stomach and insure a more perfect digestion. At first the patient was confined to milk, and milk scalded in a thin decoction of farina, with the exception of a sparing allowance of bread, crackers, and ginger-bread. As his appetite improved, oatmeal, an egg, potatoes, and broth, were added to the dietary; and, as his strength permitted him to take active exercise in the open air, milk was omitted at the mid-day meal, and fresh meat and vegetables substituted. This diet, with some substantial additions at breakfast, was followed for three years, and then discontinued, as further care seemed unnecessary.

He was strong and hardy; showed no signs of struma, not even indolent glands; joined a military company, and bore the strain on muscle and nerve as well as the others.

In October, 1878, he contracted a severe bronchitis, and some weeks after came to me, under the impression that he had tubercular disease of the lungs. Nothing was detected, however, more serious than mucous inflammation. This being subdued, he soon regained his health.

In August, 1877, I had another case of scrofulosis, identical in almost every particular with the preceding: The glands were on the same side of the neck, had the same location, presented the same appearance, disappeared in the same manner, and left only the same white line. The medical treatment consisted of quinine and iron, the dietetic of milk with lime-water, and the hygienic of air and exercise. At first he took milk alone; subsequently, milk with bread, oatmeal, potatoes, and fruit; and, at last, when he was strong enough to be out of doors, a plain meat dinner in the middle of the day. As in the previous case, the appetite was kept in advance of the supply, the regularity of the bowels promoted, exercise restricted to a point short of fatigue, and exposure to air and sunlight advised.

In the fall he had improved wonderfully in flesh, spirits, color, and strength, and during the winter he became as hale and hearty as other persons of his age. His appearance was far better than that of his brothers and sisters, whose pale and bloodless looks were in strong contrast with his full, ruddy face. The milk diet was followed for nearly a year, and then discontinued, as there seemed to be no further need of such stringent rules.

This young man was about a year older than the other, had nearly completed his second year in college, and had the ability, from his station in life, to conform to medical advice and obey the laws of health. In both cases, however, the removal of the cachexia, and the institution of healthful nutrition, was attained in about the same period of time. The success seemed due to the diet solely, and not to its accessories.

A plan of diet that can, after the failure of recognized methods of treatment, transform a weak and delicate into a strong and sturdy boy, and fit him to take his place beside those of robust constitutions in a prolonged course of severe training, must have a virtue in it meriting general recognition by the profession, although it places the theories so recently elaborated by physiologists and chemists in a light more than questionable.

In August, 1877, I was called to see a young man,

G. H., eighteen years of age, suffering from gastric fever. His digestion had always been sluggish, his assimilation poor, his muscles flabby, his nerves irritable, his health uncertain,—common characteristics of the lighter manifestations of the strumous diathesis. Though rarely ill, he had little endurance, lacked the wild, exuberant, animal spirits of youth, and had never exceeded one hundred and eight pounds in weight.

In June, 1876, he presented himself at the Naval Academy for examination, but was rejected as wholly unfitted, by his slender physical organization, for the severe ordeal to which the cadets are subjected. At this verdict he was greatly depressed, as it had always been the one great desire of his heart to follow the profession of his father, now some years dead.

The fever abating kindly, the stomach acquiring tone, and assimilation becoming active by the use of milk to the exclusion of all more stimulating articles, I told him that, by a rigid course of this character, followed for some months, he might yet attain to the vigor of body necessary to fit him for the naval service, and carry him through its hardships. He eagerly embraced the proposition, and, on the instant, was ready to meet any privations promising such full realization of his hopes.

That he might act knowingly, and follow the treatment faithfully, it was explained to him why the consumption of meat would not necessarily make muscle, or of oil, fat; or the taking of iron, blood, or of phosphorus, nerve-power; and why rich food and active medicine would almost certainly, were the digestion labored and the assimilation imperfect, intensify existing evils, and further obstruct nature in her attempts to perfect her varied vital elaborations.

The proper plan, as I strove to impress upon him, is, on the contrary, to relieve the overworked stomach by the use of food easily and promptly digested; to improve assimilation by the selection of articles containing the elements of nutrition in the proportions demanded by the wants of the system; to discard artificial aids—those designed more especially to force digestion and assimilation; and to rely solely on diet for the institution of those physiological changes whereby to set free the natural forces, and render them competent to their task.

In accordance with this plan, he was advised to take active exercise in the open air, to eat regularly and moderately, to abandon tea, coffee, spices, condiments, luxuries, and heating food, and to live almost exclusively on milk, prepared with lime-water and salt. A gobletful was to be taken at breakfast, supper, and bedtime, but not at the mid-day meal, which was to be more substantial, consisting of beef or mutton, bread, potatoes, and other vegetables. Acid fruits were allowed freely at all times of the day, for the purpose of exciting the liver and the intestinal glands, regulating the bowels, renewing the blood, and promoting the secretions and excretions. At breakfast, with the milk, were permitted bread and oatmeal or wheaten grits; and at supper, bread, crackers, and gingerbread.

As for medicine, he took for a while quinia and cinchonia, and then colombo and the pyrophosphate of iron.

By following this dietary for eight months, though he received no aid from other sources save these tonics, he developed into a vigorous young man, the picture of health, and gained thirty pounds in weight. Applying for admission into the marine service, as less exacting than the naval, he had no difficulty in passing the ordeal. One of the examiners of the

Naval Academy, a friend of his father, told him that he would have been accepted by the board without the slightest hesitation, had he then presented such a fine physique as now.

As showing the complete revolution effected, and the permanent benefit conferred by the milk diet, I should mention that, though the boy had to give up milk and conform to the regulations of a revenue cutter, his health remained intact, and his vitality equal to that of his comrades. At the present time, he holds his own with the most active and athletic, and stands at the head of his class.

In Pott's disease of the spine there is an urgent necessity for a more healthful nutrition, in order to check the disintegration going on in the bodies of the vertebrae, and supply the material for their repair. To attain this end, the quality of the food, the activity of the digestion, and the completeness of the assimilation are the main factors, inasmuch as the various structures are being constantly renewed by the product thus prepared. If the new material that replaces the old be more highly elaborated and better furnished with the elements of nutrition needed by the several parts of the organism, the foundation will be laid for permanent improvement. Now other helps are available—mechanical contrivances to support the shoulders and straighten the spine, and therapeutic means to fortify the system. If the diet be neglected, or directed without regard to the feeble powers of the stomach, the assimilation will become still more defective, and the disease still more intense, however skilfully an apparatus may be adjusted and medicine administered.

Moreover, in most cases of caries of the bones, the scrofulous cachexia is pronounced—a condition in which the taking-down and building-up processes are accomplished imperfectly. There is need, not of more, but better material; not of richer, but simpler food; and not of greater, but less work for the stomach, as already the digestive organs stagger under the burden imposed, and are incapable of acting more energetically.

The vice of scrofulosis so generally resists the best efforts of the physician, that, should disease of the bones supervene, he would anticipate little good from diet and medicine. On the contrary, his chief hope would be in mechanical devices and the silent influence of time, growth, air, sunlight, exercise, and the like.

H. B. fell, when fourteen months old, from the third-story window to the piazza below. As he fell, his back struck a blind partly open. At the time his injuries did not seem serious; there was not even a bruise to be seen; but, after a while, he was restless and peevish, cried a great deal, and screamed when moved.

Contracting pertussis in his fourth year, this pain in the back, which had steadily increased from its first appearance, was greatly aggravated by the paroxysms of coughing. Soon there was local tenderness and a projection of two or more dorsal spines. The deformity increasing, the erect posture became more and more intolerable.

In a few months the progress of the disease was so rapid, and the intensity of the suffering so severe, as to demand the use of an apparatus. This supported the weight of the upper part of the body, relieved the more urgent symptoms, promoted sleep, and allowed exercise, but accomplished little toward a cure.

Whenever his stays and braces were removed, the angularity of the spine seemed as great as, if not greater than before, and the old pains returned in full force. The boy did not improve in flesh or blood,

and appeared weary and worn. This while he had taken tonics and a full animal diet.

After the trial of the apparatus for eight months, it was determined to adopt another plan of feeding: one much lighter, less stimulating, and more assimilable, consisting of milk with lime-water, and vegetables, to the exclusion of meat, except at the mid-day meal. For breakfast he had milk, oatmeal, and bread; for dinner, broth, potatoes, bread, and rice; and for supper, milk, bread, and ginger-bread. He also had milk at ten in the morning and at nine in the evening, and, at all times, an abundance of acid fruits.

This plan, adopted in the fall of 1874, was steadily followed until the boy's improvement seemed to justify a larger range in his dietary. It was, however, as late as the winter of 1878 before he was allowed to eat at the table with the others. In the meantime the bodies of the vertebræ had become consolidated, the spine straight, save a knuckle-like projection, his body vigorous, and his health perfect.

At this date (June 15, 1879) he is as active as his fellows, stands erect, joins in rough sports and active games, and presents no peculiarity, except a slight disproportion between the length of his trunk and limbs. His height is three feet eleven and one-quarter inches, and his weight fifty pounds—a development equal to many boys of nine years—his present age.

If the milk diet can thus revolutionize digestion and assimilation, renew the normal play of the physical forces, and convert an unstable into a stable organization, and that, too, when the seeds of scrofula have taken root and borne fruit, may it not at an earlier day forestall their germination and growth, and give the child a good chance in the "survival of the fittest"? This certainly has been the case whenever a proper plan of feeding has been adopted. In such children the digestion is good, the nutrition active, the face ruddy, the body solid, and the nervous system well balanced; and rarely do the manifold ills, so common to the lymphatic temperament, disclose themselves. This holds true, even when the surroundings are none of the best, and the laws of health are violated in many particulars. The diet imparts a power of resistance that renders exciting causes inoperative.

Were children fed with due care, struma would in two or three generations be eradicated, the public health improved, the general efficiency increased, and the common happiness advanced. Even poverty would be more tolerable when strong arms fought the battle, and crime less prevalent when healthy blood nourished the heart and brain.

The milk diet being thus efficient in the scrofulous diathesis, both as a curative and preventive agent—one that steadily and silently furnishes the means of renewal and regeneration to the tissues—it is not too much to expect similar results in other diseases, the sequels of depressed vital action.

Scrofula and phthisis are near of kin, the one being often the parent of the other. At least, each springs from a common stock, and presents the same general characteristics. In tuberculosis, the treatment revolves about one central idea: the support of the vital forces in their effort to throw off the disease. The main point always is the power of resistance.

As these two diseases present the same indications, and are, perhaps, only different stages of the same pathological condition, good results ought to be attained at an early stage of tuberculosis by the milk diet.

In 1875 a boy, three years of age, slowly recovering from an attack of gastric fever, was taken with a

violent paroxysmal cough. This reduced him very much. He loathed food, perspired at night, and lost flesh. At a small circumscribed space in the upper lobe of the right lung the vesicular murmur was absent and the percussion-note flat.

Thinking the case serious, I told the parents that their boy would soon run down with consumption unless they disregarded his fancies and caprices, and enforced a systematic plan of diet; and, on the other hand, that he might possibly resist the disease and regain his health, were his appetite and digestion so restored as to afford him the requisite strength.

Compliance with rules being promised, the boy was ordered the half of a tumblerful of milk with a table-spoonful of lime-water and a grain of salt every two hours. All else, whether food or medicine, was interdicted, with the exception of twenty drops of whiskey to each feeding. Subsequently, as in the cases related above, other articles of food were added, and quinia and cinchonia given.

Near the close of my attendance, cod-liver oil, with the phosphates, was substituted for these alkaloids, and, in conjunction with the milk diet, continued four or five months.

Although the prognosis was still grave, as the permeability of the lung had not improved, yet there was cause for encouragement, as there had been a steady improvement in flesh, blood, and nerve. Eventually, the lung regained its normal condition, and now the boy seems as well as any of his playmates.

In the fall of last year a case similar to the last came under my care. There were present anorexia, emaciation, and cough, preceded by gastric disorder, and attended with dulness and harsh râles at the apices of both lungs. The treatment, with the exception of cod-liver oil and the phosphates, was the same, and the result equally fortunate, but secured in a much shorter space of time. The milk was continued alone until the digestion resumed its office, and the appetite demanded a more substantial regimen, when, as before, a greater latitude of choice was permitted.

In both of these cases there was, doubtless, at the start, a congestive condition of the gastro-intestinal mucous membrane, similar to that described by the older writers as worm fever. This congestion resolved itself under the influence of a bland, unstimulating diet, and set free the various glandular secretions, the office of which is to transform the food into chyle and prepare it for absorption by the lacteals. The digestion being thus restored, the blood was supplied with proper material, the nutrition placed on a healthful basis, and the lungs rescued from impending danger.

To me it seems plain that, however urgent the call may be to invigorate the patient and augment his vital resistance, it is of the first moment to adapt the means to the capacity of the stomach. Strong food and active medicine are not unfrequently out of place before a simple plan of diet has relieved the irritability of the *prima via*, and restored the digestive organs to their normal activity.

SCOTT'S EMULSION OF COD-LIVER OIL.—Dr. J. E. Garretson, of Philadelphia, writes that in phthisis he has used the emulsion with hypophosphites of lime and soda with notable success. When cough is troublesome he combines atropia with it; and when it does not digest well he adds sulphuric ether, diluted with two parts of alcohol, the ether being regarded as a stimulant to the pancreas.

A UNIQUE CASE OF COMPLETE PHARYNGEAL STRICTURE OF SPECIFIC ORIGIN.

By JOSEPH MEYER, M.D.,

EX-HOUSE-PHYSICIAN TO CHARITY HOSPITAL, N. Y.

(Reported with Prof. Oertel's permission from his Clinic at München.)

A MAN, thirty-three years of age, had a chancre three years ago, followed by eruptions of secondary syphilis, which got well under mercurial treatment. For the past year he had no specific trouble of any kind, and no treatment, until Dec. 25th. He then began to complain of a sore throat, which, with ordinary remedies, got no better, but rapidly worse. On the 10th of January he presented himself to Prof. Oertel at his clinic, when, upon examination, the posterior wall of the pharynx, and sides of the pharynx and uvula were inflamed, reddened, and infiltrated; on the uvula beginning ulcerations were noticed, also on the surface of the tonsils. At this time a gargle was ordered, and he was asked to call again in a few days. Prof. Oertel having been called out of town on the 13th of January, the patient did not again present himself till the 15th, when he was brought into hospital in a dying condition, almost suffocated, with intense dyspnoea, breathing long and wheezing, inspirations 10-12 per minute, pulse almost imperceptible, surface of body cold, face and hands cyanosed, and almost voiceless and speechless. Examination by Professor Nussbaum gave little satisfaction, simply showing an occlusion of the laryngo-pharyngeal space by a stricture, ulceration of posterior pharyngeal wall in a reparative condition, uvula drawn to right pillar of pharynx and there attached; and perforation of soft palate. What condition the larynx was in could not be determined; opening through which he breathed could not be seen. It was supposed that the ulcerative process had destroyed the epiglottis, and closed the upper portion of the larynx. The indication was tracheotomy, which was immediately performed by Professor Nussbaum, with prompt relief to the patient, so that he was able to leave the hospital in a few days, after having been put on mixed treatment. On the 25th of January he again presented himself to Professor Oertel for further treatment. Examination showed an almost complete stricture of the pharynx, extending from the base of the tongue to the sides and posterior wall of the pharynx, a small opening, not even admitting a probe, a little to the left of the centre of the stricture, which formed a sort of lid over the larynx and œsophagus. Through this small opening the patient took food and breathed. Posterior wall of pharynx of an ash-gray color, presenting an arch-like appearance. No more ulcerations; soft palate perforated and uvula attached to right side of pharynx. Patient wore a tracheal tube; now only had occasional attacks of dyspnoea, with an occasional choking and coughing when he attempted to swallow quickly. He could only take liquid food, but sufficient to sustain him. Opinion of Professor Oertel was same as that of Professor Nussbaum, that epiglottis was destroyed and upper portion of larynx was closed by the stricture. Condition of vocal cords not known; how larynx closed during deglutition—for food and air passed through the same small opening—was not known. I thought, and Professor Oertel agreed with me, that during the act of deglutition the base was lifted and drawn backward in such a way as to approach post-pharyngeal wall, bringing the small aperture over the œsophagus, at same time closing the larynx, the closure being aided by the aryteno-epiglotti-

dean folds, which, although they could not be seen, were supposed present, and cases of complete destruction of the epiglottis, reported by Bruns, Türk, etc. Its function was known to be replaced by those folds, and in my opinion aided by the tongue (base) approaching the pharyngeal wall. Professor Oertel proposed to operate; to dilate the opening with a knife. Sounds were passed every other day to get the patient used to an instrument, till February 10th, when the first operation was performed. An incision was made forward toward the tongue; bleeding was slight; he was ordered to gargle cold water. At this time it was noticed that he could gargle much easier. When he was asked if it pained him, he said, "only a little" so distinct that everybody present understood him, he having been almost voiceless and entirely speechless. This operation was followed by two more on the 13th and 18th of February, two lateral incisions then having been made; opening would then admit a finger. Examination after second operation showed, to the astonishment of all present, that the larynx was perfectly intact, epiglottis was entire, vocal cords were normal. He could now breathe without the tracheal tube, deglutition was no more interfered with, and the patient rejoiced in the fact that he was again able to drink lager-beer.

The principal points of interest in this case are the completeness of the stricture, its seat, the rapidity of the ulcerative process, the rapidity of the reparative process at the time without specific treatment, and the larynx being perfectly intact.

Reports of Hospitals.

THE PHILADELPHIA HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

(Prepared for THE MEDICAL RECORD.)

SPRAINS.

THE routine treatment of sprains is that first introduced by the late Dr. Paul Goddard. The injured part is placed in a bath at the temperature of 70° F. The temperature of the water is then gradually raised until the extreme point of toleration is reached. This hot-water treatment has in every instance been followed by the most excellent effects.

GONORRHOEA IN THE MALE.

Dr. J. H. Brinton employs carbolic acid, in the shape of a solution containing gr. ij. of the acid to f. ʒi. of lime-water, as a local application in the acute stage of the disease. At the same time cubeb is administered internally in doses of a tablespoonful in half a tumblerful of water three or four times a day. This dose is pushed until diarrhoea or nausea supervene, when the quantity is reduced.

STRICTURE.

Dr. S. W. Gross considers that the only rational treatment of stricture consists in the restoration of the normal calibre of the urethra at the affected portion, and that the meatus should therefore be enlarged so as to admit of the passage of an instrument of the size adapted to restoring the constricted part (whose dimensions may be ascertained by means of the urethrometer devised by Dr. Gross) to its original dimen-

sions. Dr. Gross claims, however, that *dilatation never effects a permanent cure*, and should therefore never be employed except in those cases where there is disease of other portions of the urinary apparatus.

He treats stricture almost entirely at present by internal urethrotomy, since he has determined from post-mortem examinations that there are very often submucous bands which resist the action of the divulsor.

Having determined upon internal urethrotomy, he first allays the spasm and tenderness of the urethra by passing at first, and at long intervals, a moderate-sized conical steel bougie, gradually increasing the size of the instrument and decreasing the length of the intervals. If the meatus is the seat of stricture, or is smaller than the rest of the urethra, it is cut as a preliminary measure.

Ten grains of quinia are given before the operation, and the patient is made to pass his water so that the wound made by the urethrotome may have become glazed before the next act of micturition. The rectum is always emptied before the operation. Dr. Gross employs a urethrotome devised by himself, and made by Mr. G. Tiemann, of New York.

Immediately after the operation a conical steel bougie, whose size corresponds to that of the normal urethra, is passed and withdrawn, and one-third of a grain of morphia is thrown under the skin. The patient is then confined to bed for forty-eight hours. The bougie should be introduced once every day for some time after the operation. Dr. Gross considers internal urethrotomy from behind forward the most effectual operation.

The treatment of stricture of the urethra followed by Dr. Brinton is not an exclusive one. In the majority of cases he relies upon gradual dilatation, especially when the stricture is situated at or near the membranous portion of the urethra. In making dilatation he uses the ordinary Thompson's sound, and when much resistance is encountered he stretches the stricture rapidly with Thompson's dilating blades. In strictures of the spongy portion of the urethra, when, from any cause, slow dilatation is undesirable, he practises division by Holtz's method, and also internal urethrotomy, using for the latter purpose an ordinary Charrière's instrument. He prefers urethrotomy to division, particularly in irritable and resilient strictures. Strictures at or near the meatus he divides. In practising the common process of gradual division, when the stricture is tight and the opening small or tortuous, he usually employs whalebone bougies and Gouley's tunnelled catheters. The whalebones he makes himself, and they are very much finer than those to be bought in the shops, which, nine times out of ten, are not sufficiently flexible, and are therefore useless. Dr. Brinton insists with great emphasis upon the permeability of all strictures, with occasional exceptions, *i. e.*, those of traumatic origin. In difficult cases the passage of the whalebone is a work demanding great dexterity and gentleness, and, according to this surgeon's teachings, cannot be confidently anticipated if the patient has been practised upon the same day with instruments of larger diameter and with rounded points. When a stricture is suspected, or known to be a tight one, he invariably uses first the whalebone and over it the tunnelled catheter, deferring to a later stage of dilatation, instruments flexible, or soft, of increased size.

In the practice of the Philadelphia Hospital Dr. Brinton deprecates unnecessary interference with the urethra. The patients in this institution are paupers collected from the lowest ranks of life, with constitutions utterly broken down by exposure and debauch.

In his judgment the results obtained from operations upon such subjects are greatly inferior in point of success to those which attend like operations in private practice.

Progress of Medical Science.

COTO BARK.—Dr. Frommüller and Prof. Balz have been experimenting therapeutically with coto bark, a plant whose botanical position is not yet settled by naturalists. The powdered bark and a tincture made of one part bark to nine of alcohol were employed, the quantity of the latter used varying from 0.50 grms. to 25.00 grms. a day. Out of eighty-five cases of colliquative diarrhœa, fifty were cured, twenty-six were benefited, and nine showed no results after the administration of the drug. In many cases the diarrhœa returned within a few days, but a repetition of the treatment effected a final cure. As a rule, the success was directly proportional to the dose, the medicine failing when small doses were used. The profuse sweating of phthisis was also controlled by it to a very considerable degree. Of ninety-one observations recorded by Frommüller, it disappeared entirely in thirty-four, was diminished in twenty-six, and in eight was not affected. An alkaloid, termed *cotoïne*, is obtained from the bark by means of ether, which may be used instead of the substance itself, 0.15 gm. being equal to 5.00 grms. of the tincture. Another crystalline body, *paracotoïne*, is also obtained, and was used by Prof. Balz in cholera (See Vol. XIV., MEDICAL RECORD, p. 450), but owing to the small quantity of the drug in his possession he was unable to form a satisfactory opinion of its action; the results, however, were sufficiently favorable to recommend its further trial.—*Bulletin Général de Thérapeutique*, April, 1879.

TUBERCLES OF THE VAGINA AND CERVIX.—M. Cornil reported to the *Société des Hôpitaux* two interesting observations of this affection, one made by himself and the other by M. Rigal. The first case was a phthisical woman who presented a tumor of the lower part of the pelvic peritoneum, accompanied by uterine pains and leucorrhœa. Examination with the speculum revealed a superficial erosion of the cervix near the os, about half a centimetre in diameter, with sharply cut edges and a yellow base; on one side there were three small, slightly prominent, yellow points. The ulceration was touched with tinct. iodi., and rapid cicatrization set in; three weeks afterwards the patient quitted the hospital almost entirely well. An ulceration on the frenum of the tongue marked by the same yellow, tuberculous granulations, also cicatrized readily. In the second case, the autopsy showed a general miliary tuberculosis; the cervix and the vaginal walls presented a white granular plaque, not extending into the cavity of the cervix. M. Fournier in discussing the report admitted the rarity of tubercle of the cervix. He had on several occasions observed ulcers of the neck of the womb, the nature of which he could not determine; but the women were tuberculous, and he asked if these ulcerations might not be part of the disease. The history of tuberculosis of the cervix is as yet undeveloped, not being further advanced than that of tuberculosis of the tongue, before M. Trélat called attention to the yellow points. Among the scrofulous and phthisical, ulcerations are frequently observed which may be considered tuberculous. M. Cornil agreed with M. Fournier, but

doubted whether all the ulcerations observed in tuberculous patients could be attributed to tuberculosis.—*Bulletin Général de Thérapeutique*, April, 1879.

THE CLIMATE OF NICE AND ITS THERAPEUTIC ACTION.—M. Grellety does not consider the climate of Nice favorable for phthisical patients. The sudden change of temperature in the evening is undesirable; nor are the inhabitants found to be less subject to the disease than are those of other cities. A Lyons journal complains that the vital statistics are not accurate, most of the deaths from phthisis being placed to the account of other diseases, for fear of frightening away the visitors; in like manner the reports of dangerous zymotic diseases are pigeon-holed. According to M. Grellety the true object of Nice is the cure of gout. The gouty, no matter what their condition, all receive benefit, providing they live properly, renouncing their bad habits and hygienic errors, remain sober, and live in the open air, taking sufficient exercise to oxygenize their blood and restore to the sudoriferous glands their normal activity.—*Bulletin Général de Thérapeutique*, April, 1879.

SCLERODERMA: TREATMENT BY THE CONTINUED CURRENT.—Dr. Armaingaud states that he has obtained excellent results from a persistent use of the continued current in a severe case of scleroderma. The patient was a married woman, forty-one years of age; she had always enjoyed good health, but had never menstruated and had never been pregnant. The affection first showed itself in the neck, seven years before she was seen by Dr. Armaingaud, and had gradually extended to the face, arms, chest, breast, and abdomen, the lower limbs being unaffected. The tongue was thickened and very rigid, and its movements were greatly circumscribed. The face was entirely expressionless, and all movements of the affected parts were very difficult and incomplete. The skin had a board-like hardness; it was thickened as well as indurated, but presented none of the cicatricial spots usually met with in this disease. There was no atrophy, the affected parts having actually gained in volume and become more rounded; there was, however, nothing at all resembling œdema. The affected portions of the skin were slightly cyanosed, in consequence either of the impediment to the respiration offered by the rigidity of the thorax, or of a paralytic dilatation of the small cutaneous vessels. On the right arm, where the disease was most marked, the skin was very dry and parchment-like, and it was impossible to raise a fold or make a depression in it. When the finger-nail was drawn sharply across it, a white line was left, which did not become red until the following day. The eyeball could not be pressed back into the orbit, evidently in consequence of induration of the cellular tissue behind the ball. The optic papillæ were hyperemic and the retinal veins dilated, but vision was emmetropic and accommodation normal. There was incomplete anæsthesia of all the affected parts, and particularly a very marked delay in the transmission of sensations. Even deep punctures in the arm were not felt until a quarter of an hour afterward; the pain then was less intense than it would be under normal conditions. Reflex movements were also retarded. The patient had a sensation of cold in the right arm, and the temperature there was 1° C. lower than in the left arm. She complained also of great sensitiveness to cold, but not of any decided pain. In the early stages of the disease she had suffered almost constantly from pruritus, which had been particularly severe at night.

From the favorable results of treatment in this case,

Dr. Armaingaud believes he is justified in drawing the following conclusions:

First.—That electrization with continued currents is indicated in the treatment of scleroderma, and may be expected to give favorable results, if not in all forms and degrees of the malady, at least in the form characterized by thickening and induration of the skin without cicatricial patches or ulcerations.

Second.—That the electric current acts not only on the portions of the skin covered by the poles, but also, through the medium of the spinal cord, on the parts not electrified.

Third.—That the favorable action of the constant current, and especially the generalization of its effects through the medium of the spinal cord, furnish additional support to the theory which makes of scleroderma a *trophoneurosis*, that is to say, a trophic affection dependent on an alteration in the nervous centres.—*Archives Gén. de Méd.*, June.

LIGATURE OF THE COMMON CAROTID FOR DENTAL HEMORRHAGE.—M. Hémond reports a case of ligature of the common carotid for hemorrhage following the extraction of a molar tooth. The usual remedies had been applied without success, and, with the consent of five of his confrères, M. Hémond performed the operation. The result was unsatisfactory, the hemorrhage not being controlled. The ligature came away on the twelfth day, after which ergot, and then sulphate of quinine were administered, and it was only after the exhibition of the latter drug, that the bleeding was checked. There was question here of the existence of the hemorrhagic diathesis, which would explain the difficulty encountered. M. Hémond preferred tying the common to the external carotid, on account of the difficulties presented by the latter operation. In the discussion which followed the presentation of this case to the *Société de Chirurgie*, M. Tillaux remarked that the operation was a very dangerous one, and should only be used as a last resort. He always preferred the actual cautery, and tamponing with charpie and perchloride of iron. The tampon should be kept in position by digital pressure, which should be maintained as long as possible, the friends of the patient being generally available for this purpose. With regard to the choice of the artery to be ligated, he thinks that, as the hemorrhage certainly comes from branches of the external carotid, that vessel should be selected. It is more difficult of access than the common carotid, but the dangers following the operation are less. M. Verneuil agreed with M. Tillaux in the choice of arteries, but he thinks that all these cases should first be treated with sulphate of quinine in doses of one or two grammes per day. He had seen dental hemorrhage in a medical student yield after the second gramme. There is question in these cases of the hemorrhagic diathesis, which demands internal treatment. M. Magitot advised the use of gutta-percha, which can be softened by heat and moulded into form, and the necessary pressure may be obtained against the superior maxillary. If the tooth cavity be first filled with chloroform, which dissolves the gutta-percha, the plug adheres intimately to the soft parts, and completely arrests the hemorrhage.—*Journal de Médecine et de Chirurgie*, June, 1879.

THE LARYNGOSCOPE.—It is recommended that a cloth moistened with glycerine be lightly passed over the laryngoscopic mirror before it is used. The water in the expired air is completely dissolved by the glycerine and many examinations can thus be made without any heating.—*Lancet*.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

LITHOTRITY WITH EVACUATION OF THE FRAGMENTS.

II. THE OPERATION AND INSTRUMENTS.

THE instruments employed in this operation are a lithotrite, evacuating catheter, and washing-bottle. The lithotrite is introduced into the bladder, and employed during from ten to twenty minutes in catching and crushing the stone and its fragments. Then it is withdrawn, the evacuating catheter introduced, and all fragments small enough to pass through it washed out. This is repeated as often as may be necessary. It is seldom, if ever, desirable to use the lithotrite for more than fifteen minutes at a time. The work is done more expeditiously if the catheter is frequently employed to get the fragments out of the way, and the reason is a simple one, for the mass of small fragments, if not removed, protect the larger ones from being caught by the lithotrite. It frequently happens that, on the reintroduction of the lithotrite after washing, a large fragment is caught immediately, although only small ones were encountered at the end of the previous crushing. Bigelow makes use of longer intervals, and also of a much longer time to complete the operation than is usual with other operators; probably the two facts stand in the relation of cause and effect.

The lithotrite is handled in the usual manner; that is, the fragments are usually caught by depressing the floor of the bladder with the female jaw, so that they will roll down upon it, and then closing the male jaw upon them; or by opening the instrument widely, turning it upon its side, and sweeping the lower surface of the bladder from before backward with the male jaw. The washing is done by introducing the catheter, emptying the bladder more or less completely through it, and attaching the bulb, previously filled with warm water. Then, by alternately compressing and relaxing the bulb, the water is made to run into

and out of the bladder, and the fragments which are brought out by the return current sink immediately into a glass receptacle at the bottom of the bulb. During this manœuvre the end of the catheter is kept pressed against the floor of the bladder, and its eye turned in different directions. As soon as the fragments cease to come in any considerable numbers, the catheter is withdrawn and the lithotrite reintroduced.

It is evident, in view of this prolonged use of the lithotrite, that its jaws must be so constructed that they will not become impacted by the fragments, a danger that is especially great when the stone is phosphatic. Even in the old operation this same need was felt, for an impaction sufficient to separate the jaws so far as to render the withdrawal of the instrument difficult can be produced by one or two crushings. Many devices have been proposed to meet the want; among them a successful one by Reliquet some four or five years ago. Reliquet cut lateral grooves sloping backward across the face of the male jaw, and corresponding fenestræ in the back of the female jaw through which the ridges separating the grooves of the male jaw could pass; he thus supplied two routes through which the detritus lodged between the jaws could be forced, one backward through the grooves, the other forward through the fenestra. In Prof. Bigelow's instrument the same principle of lateral grooves is used, the difference being that in Reliquet's the grooves have parallel sides, while in Bigelow's they are triangular and larger. In each case they run from the left edge of the face of the jaw to the right side, and from the right edge to the left side alternately. There is no fenestra in the female jaw of Bigelow's instrument, and it works perfectly well without it. Another point requiring especial attention is that the danger of catching the mucous membrane of the bladder between the jaws shall be reduced as much as possible. With this object Bigelow rounds the edge of the rim of the female jaw, makes its depression shallow, and lengthens and broadens the heel.

Sir Henry Thompson uses two small non-fenestrated lithotrites, crushing two or three times with one, withdrawing it loaded with débris, and using the other while the first is being cleaned. Dr. Keyes uses a lithotrite with a fenestra occupying the entire floor of the female jaw, and with the shaft of the male blade so lengthened that its jaw can be driven through this fenestra so as to free it completely. Pinching of the bladder is prevented by making the male jaw at least a millimetre narrower and shorter than the fenestra.

It is not necessary to reduce a stone to powder; it is sufficient to break it up into fragments small enough to pass through the evacuating tube. Bigelow's and Keyes's lithotrites both do this, and apparently there is little choice between them, the objections urged by each against the others being either of trifling im-

portance or not borne out by experience. Keyes's is the simpler and lighter instrument.

One of the most valuable modifications of the lithotrite was made by Sir Henry Thompson in giving it the cylindrical handle which so greatly facilitates manipulation, and in the arrangement for locking the two blades and throwing the screw into gear by lateral catches moved by a flat button on the upper side of the handle. Prof. Bigelow has substituted for the latter device an arrangement consisting of a cylindrical catch at the end of the handle moved by a turn of the wrist. He attaches considerable importance to this modification on account of its alleged greater facility of manipulation; but, even if this claim is well founded, a serious objection to the modification exists in the liability of the instrument to break at this point where the reaction of the force exerted through the screw upon the stone is received. This objection is not a theoretical one, for one of Bigelow's instruments broke at this point upon its first trial, the cylindrical catch being torn bodily away from the end of the handle. Thompson's catch cannot be broken in this manner, and it is certainly easy enough of manipulation to make greater ease dearly purchased at the expense of strength.

Bigelow's evacuating tubes are perfect. He has two models, a straight and a curved, and various sizes; the largest, we believe, about 11 mm. in diameter, No. 34 of the French scale. As he so well says: "The best size for the tube is the largest the urethra will admit." The principal modification in the construction of these tubes is in the size, shape, and location of the eye, which is close to the end and large enough to admit the largest fragment that will pass through the rest of the tube.

His evacuating bottle consists of an oval rubber bulb with a sort of large, strong, glass test-tube at one end, and a rubber tube, a foot or more in length, at the other. When in use, the rubber tube is attached to the evacuating catheter, and the bulb is held upright with the glass below. It works admirably, and the only objections to it are that even with the best care it is practically impossible to prevent the admission of air into it and wetting of the bed when coupling it to the catheter, and that the fragments have to pass through a foot of tubing before reaching the bulb. The latter is a small matter, and the former would be readily overlooked if Thompson's bottle did not work so much more satisfactorily in this respect. As the connection with the interior of the bladder is made at the highest part of the bulb, any air contained within the tube or catheter is forced at the first contraction into the bladder, and is there churned up with the water in a manner that probably somewhat impedes the escape of the fragments, and certainly prevents satisfactory auscultation through the abdominal walls.

Thompson's washing-bottle has the form and the

glass tube of Bigelow's, but it dispenses with the rubber tube, and is coupled directly to the catheter by means of a short brass tube provided with a stop-cock and entering the bulb at its lower end just above the glass tube. At the top of the bulb is another brass tube and stop-cock, through which the bulb can be conveniently filled with water. With this instrument the washing can be conducted with great facility while the patient lies in his bed, and without the escape of a drop of water while coupling. Any air that is present in it or the catheter rises at once to the top of the bulb, where it is entirely out of the way, and the fragments have to traverse only the length of the catheter and the short brass tube before falling into the glass receptacle. The rush of the water into and out of the bladder is so noiseless that the slightest click of a stone against the catheter can be heard, if the ear is placed upon the hypogastrium, and thus auscultation becomes a valuable adjunct of the searcher in determining the presence of a stone or any of its fragments.

ENGLISH MEDICAL STUDENTS AGAIN.

In our notice of the remarkable article in the *Fortnightly Review* upon the medical men of England, we stated that we had seen no denial of the statements of Mr. Gilbert. Our attention was soon called to an answer written by Mr. Robert Brudenell Carter, an oculist of London, for the *Contemporary Review*. We regret that we have not been able to sooner notice Mr. Carter's reply. Mr. Gilbert is unknown to probably nearly all of our readers, but Mr. Carter will be remembered by many American medical men who made his acquaintance when he visited this country in 1876, and was a member of the Medical Congress held in Philadelphia, and the ophthalmological in New York. Many others know him as an interesting and instructive author, who holds an excellent professional position in London. Mr. Carter has also, we believe, held a responsible position on the staff of the *Times*, and may therefore, on all accounts, be said to be a fitting person to reply to Mr. Gilbert. Mr. Carter makes short work of many of the assertions of the *Fortnightly*. He simply denies them: "Mr. Gilbert's assertions are not only grossly inaccurate, but they are destitute even of the shadow of a foundation." This is the way many of the statements are disposed of: "Of 2,441 medical students in London in 1878, only ten are known to have come under the notice of the police, and these for no grave misdemeanor." It will be remembered that Mr. Gilbert put the number at 400.

Mr. Gilbert seems to be as unknown to the professors in the English medical schools as he is to us, for Mr. Carter's inquiries fail to find that the authorities of the larger schools had ever heard of him. Mr. Gilbert is said to have sent a proof of his article to one surgical teacher, to have it returned with a strong

condemnation and denial of his statements. The denials of the *Contemporary* as to the statements regarding the attention of patients, are not quite so comprehensive as those in respect to the moral character of the medical students.

From our own very limited experience in London hospitals, and from our reading on the subject, we are inclined to think that a good deal of the work by the medical men nominally in charge is perfunctory,—a result, as we think, of the vicious system which obtains in England as well as here, of crowding hospitals and infirmaries with patients who, on account of ability to pay, have no business there. These patients so fill the hospitals that medical men, did they give them all the necessary time, could do no private practice. Besides, in London as in New York, some men have so many hospital appointments that they do not always do justice to all their public work.

Mr. Gilbert's criticisms upon the system that makes a score of little medical schools in London, where there should be one or two large and well-organized ones, like those of Vienna or Paris, remain, however, unanswered, simply because it is impossible to praise such a mode of dividing up the energies of medical teachers, that with an equal arena would always, as they now do at times, rank with any in the world. Hospitals should everywhere, each one of them, in our opinion, be made use of to teach medical students and practitioners; but to make each one of them a medical school, with all the necessary appointments, is not only to fritter away the money of the beneficiaries, but also to seriously impair the influence of men who should have the advantage of large classes, and whom large classes, instead of the beggary two score or so of such medical schools as Charing Cross, should hear. The character of English medical students may be said to be fully vindicated by Mr Carter, if any vindication were needed; but the wisdom of the English system of medical instruction may still be doubted.

It remains a puzzle to us, that a respectable English journal like the *Fortnightly Review* could admit such false statements, and such incorrect statistics, as those of Mr. Gilbert's are proven to be. There seems to be some careless editing, even in the land that sometimes claims to furnish good taste for the civilized world. What with parliamentary obstructionists, the craze over disreputable but gifted actresses, and lying articles in respectable journals, we shall soon come to charge our English consins with faults that they have sometimes attributed to us, and described as peculiar to our nationality.

BRITISH MEDICAL ASSOCIATION.—We give our readers a special report of the proceedings of the British Medical Association, for the first two days of its annual meeting. A report of the remaining part of the meeting did not reach us in time for insertion in the present number.

Reviews and Notices of Books.

LESSONS IN GYNÆCOLOGY. By WILLIAM GOODELL, AM. M.D., Professor of Clinical Gynæcology in the University of Pennsylvania; Fellow of the American Gynæcological Society; Corresponding Fellow of the Obstetrical Society of London, etc. With eighty illustrations. Philadelphia, Pa.: D. G. Brinton, 115 South Seventh Street. 1879.

THIS book, containing nearly 380 pages, is not a treatise upon diseases of women, but mainly the outcome of clinical and didactic lectures to advanced students. It consists of a series of twenty-nine lessons. In the first we are told what ordinary working tools the beginner in gynæcological practice should purchase and carry in his satchel. To the list which he has given we believe a catheter and a uterine probe might with advantage be added. It may be that he intends to use the aluminum wire applicators as probes. The remarks made in this lesson regarding the use of the uterine sound, the propriety of having a female attendant in one's office, and keeping full notes of office cases, are valuable and practical.

In the second lesson the author introduces Diseases of the Urinary Apparatus, and first describes caruncle of the female urethra and its treatment. Removal by means of the actual cautery has proved most satisfactory to him, and it is a good method. If the thermo- or galvano-cautery is not at hand, a heated wire may be used.

The third lesson is consumed with Observations on Vesical Disorders of Women. In this lesson Dr. Goodell brings out a fact which, if more generally known, would save many suffering women from the annoyance of wearing a pessary. Pessaries are good in their place, but to employ them to support a physiological antelexion is, to say the least, foreign to their designed use. Antelexion, the author believes, is the natural condition of the womb in virginity and sterility, and we believe this is an established fact, although not so generally recognized as it should be. With reference to dilatation of the urethra for the cure of chronic cystitis, Dr. Goodell says: "Candor compels me to mention one objection to this operation, and that is the possibility of permanent incontinence following it." The general candor of the book is here manifested, and we might close our review with the statement that its author is a safe medical adviser, for in none of his own cases has incontinence followed the operation. There are men, unfortunately, who, with such an invariable success in any gynæcological procedure, would be dangerous authors, unless their writings were for some obscure medical journal with limited and rapidly decreasing circulation.

Fistulæ of the Female Genital Organs is the title of the fourth lesson, which embraces the uro-genital, the recto-vaginal, and the perineo-vaginal. These, says the author, are, in a vast majority of cases, due to the disuse or tardy use of the obstetric forceps. In this and the chapter following, the usual operative procedures are described, and, in addition, that of Closure of the Vulva for Incurable Vesico-vaginal Fistula. Practical suggestions are met with at various points, and the text is as interesting as a story.

In Lessons VI. and VII. we find a brief, sensible, advanced, and rational discussion of the Causes, the Prevention, and the Cure of Laceration of the Female Perineum. The ounce of prevention being worth a

pound of cure is the key-note to the value of these lessons. He advises the immediate operation without qualification, but disarms the reviewer by saying that he is well aware of the sharp criticism which such advice will receive by some very good authorities. An expression of honest opinion is entitled to candid consideration, and must stand or fall according as it is sustained by or succumbs under practical application. In speaking of the operation he recommends that the bowels be kept locked up. This is the established rule, and yet, of late, some good men have been operating with success by keeping the bowels soluble from the beginning.

Local and Constitutional Treatment of Chronic Metritis and Endometritis forms the title of Lesson VIII., which embraces some common-sense suggestions regarding local applications to the cervical and uterine mucous membranes. Yet here we meet with a startling statement, namely, that "no matter how severe or how mild the treatment of uterine disorders, the percentage of accidents will be about the same, and that a very low one." This statement may answer for cautious men, but it is hardly in keeping with the author's usually prudent recommendations. We do not believe that it is a safe proposition to be given even to "advanced medical students," and, were we of the female sex, we certainly should prefer to have our uterus inspected from another point of view. The statement in the same lesson, that "when girls or unmarried women exhibit symptoms of uterine trouble" all measures should be tried before resorting to digital examination or to local treatment, sounds very much like the old obstetric advice to talk about the moon, the man in the moon if needs be, the manufacture of cheese, the weather, etc., when the first entrance to the lying-in chamber is made. Sick women go to the physician to get cured, and he as a conscientious practitioner of medicine has no right to place patients on the pedestal of false modesty and shoot pills at them in the dark. It is his business to find out at the very earliest hour practicable what the matter is with his patient, and, if she is a sensible woman and is approached in the spirit of honesty and desire to relieve her of her physical ailment, she will lay no obstacle in his way.

In Lessons IX. and X. the author speaks of the Versions and the Flexions of the Womb, and advocates mechanical support by means of pessaries. It seems to us that he does not sufficiently qualify his statements regarding the use of the uterine repositors, and leaves the student to infer that it is an instrument which can be employed essentially without fear or favor. True, it is in keeping with the position already noticed, that the uterus can be dealt with harshly without exhibiting marked retaliation; but we hesitate before indorsing the recommendation.

In Lesson XI. we notice a practical rule regarding the Use of Tents for Dilating the Cervical Canal. The Intra-uterine Stem-pessary receives a *guarded* recommendation in Lesson XII., and in Lesson XIII. the author passes to the study of Pessaries and Abdominal Supporters. In Lessons XIV. and XV. he discusses at some length the Etiology of Prolapse of the Womb, and adopts Dr. Isaac E. Taylor's view with reference to prolapse from hypertrophic elongation of the supra-vaginal portion of the cervix, namely, that it is the supra-glandular portion of the cervix—the isthmus—which is drawn out from the corpus, and that at the expense of its thickness. These lessons present a worthy *résumé* of the views and the objections thereto entertained regarding the etiology of this very common affection.

Laceration of the Cervix Uteri is the title of Lesson XVI., and nowhere, either in speaking of the frequency of the lesion or the operative interference for its cure, has the author even mentioned the name of Emmet, who was the first to describe the lesion, devise an operation for its cure, and to bring its pathological significance prominently before the profession. In a home author, this omission is entirely inexcusable. The description of the lesion and the method of treatment are substantially those with which the profession is already familiar.

Cancer of the Womb and Vegetations of the Endometrium are the titles of Lessons XVII. and XVIII. Lesson XIX. is devoted to Polypus of the Womb; and the study of Fibroid Tumors of the Womb occupies Lessons XX. and XXI. Passing Lesson XXII., in which Spaying for Fibroid Tumor of the Womb and for other Disorders of Menstrual Life is considered, we come to Lesson XXIII., which is upon Ovarian Cyst, its Diagnosis, its Treatment by Tapping, by Injections of Iodine, and by Drainage. Ovariectomy by Abdominal and by Vaginal Section is pleasantly discussed in Lessons XXIV. and XXV., and then the author passes to the subject of Nerve-tire and Womb-ills in Lesson XXVI. which consists of his Address before the American Gynecological Society at its Annual Meeting, held in Philadelphia, September, 1878. In Lesson XXVII. are given some practical and useful hints, both special and general, for the Prevention of Uterine Disorders. A subject is taken up in Lesson XXVIII. which, according to our recollection, has not been previously discussed in a medical book. It is the relation which faulty closet-accommodations bear to the diseases of women. We must congratulate the author upon the full, frank, and common-sense expressions which he has given us in this chapter, and we believe the practical benefit which would follow scrupulous attention to the advice therein given would amply reward every family in the world for obtaining a copy of the book. "Such closets as invite rather than repel, which give comfort and ready privacy to the evacuations of the body," will do much—very much—toward maintaining it in the greatest possible degree of health.

The book closes with a lesson on the sexual relations as causes of uterine disorders. The questions discussed are worthy of candid consideration, and the author has acquitted himself with grace.

The book, as a whole, is well published, and will be acceptable to the profession, notwithstanding the occasional taint of unqualified statements upon questions which, by general acknowledgment, are yet mooted.

EXAMINATION AND VERIFICATION OF WEIGHTS AND MEASURES OF PRECISION.—The College of Pharmacy of the City of New York has provided itself with special balances and standard sets of troy and decimal weights, to be used in the examination and verification of decimal, troy, or apothecaries', and all other kinds of weights. The college is ready to simply pronounce on the fact whether certain weights are correct or not, not to make incorrect weights correct. It is a matter of great importance that every dispensing pharmacist has weights which are correct. It is a notorious fact, and one of which pharmacists as well as physicians are aware, that many, if not most, of the cheaper weights sold in trade are unfit to be used as weights of precision by pharmacists or physicians.

Reports of Societies.

BRITISH MEDICAL ASSOCIATION.

FORTY-SEVENTH ANNUAL MEETING.

Held in the City of Cork, Ireland, August 5th, 6th, 7th, and 8th, 1879.

(Special Report for THE MEDICAL RECORD.)

TUESDAY, AUGUST 5TH—FIRST DAY.

THE Association was called to order at 3 P.M. by DR. R. A. W. FALCONER, President, who was accompanied to the platform by DR. O'CONNOR, of Cork, the President-elect.

The minutes of the last meeting were read by the Secretary, MR. CROWKE, and approved.

DR. FALCONER then made brief reference to some of the more salient occurrences which had taken place in the Association during the past year, thanked its members for the kindness he had received during his year of office, and then introduced DR. O'CONNOR, the Senior Medical Professor of the Queen's College, and the President-elect of the Association.

HONORARY DEGREES IN MEDICINE.

DR. W. K. SULLIVAN, President of Queen's College, announced that the Senate of the Queen's University, Dublin, had conferred the honorary degree of M.D. on the outgoing and on the incoming Presidents.

RESOLUTION.

DR. WATERS offered the following resolution, accompanied by appropriate remarks:

Resolved, That the best thanks of the Association are due and are hereby given to Dr. R. A. W. Falconer, for the able and courteous manner in which he has discharged the office of President during the past year.

DR. ALFRED CARPENTER, as President of the Council, seconded the resolution, and it was unanimously adopted amid great applause.

DISTINGUISHED FOREIGNERS PRESENT.

DR. CARPENTER then announced the following distinguished foreigners, who, although not members of the Association, would be its guests during the present meeting: Professor Charcot, Professor Ball, Dr. Gallard, Dr. Bonnafont, Dr. Sowerby, and Dr. Gueneau de Mussy, of Paris; Dr. Hirschberg, Dr. Weber Liel, and Dr. Madton, of Berlin; Dr. Giacinto Pachiotti, of Turin; Dr. Coodes, of Geneva; Dr. Lewis A. Sayre, President of the American Medical Association; Dr. G. M. Beard, Dr. E. Seguin, and Dr. Gray, of New York; Dr. Hodgins, of St. Louis; Dr. Yandell, of Louisville, Ky.; Dr. Lawrence Turnbull and Dr. Da Costa, of Philadelphia, Pa.; and Dr. A. B. Palmer, of the University of Michigan.

The distinguished guests were received with applause.

PRESIDENT'S ADDRESS.

DR. D. C. O'CONNOR then delivered the annual address, of which the following is a brief abstract: He first referred in suitable terms to his deep sense of gratitude for the honor conferred upon him by the Association in making him its presiding officer. Following the example of some of his predecessors, he pointed out circumstances of interest associated with the locality of the meeting, and spoke of what Spencer calls the "beautiful citie," with its admirable sanitary appointments and its æsthetic surround-

ings, its hospitals and its monasteries, its freedom from taxes, its School of Design, and its Musical Academy. Leaving the physical aspect of the city in which the Association assembled, he remarked that a brief survey of the composition of the Association, the brilliant genius of many of its members, would lead to a feeling of disappointment that greater results had not followed, which would place medical doctrines on a firm, lasting basis, rendering them free from doubt or controversy.

For the practical man—the every-day working physician—there was presented the important duty of collecting facts from which the man of genius would derive general principles, and thus assist in bridging over the large space which divided physiology and pathology from practical medicine. To make a good syllogism, with physiology and pathology as major and minor premises, and the treatment of disease as the conclusion, it remained still the difficulty to remove the disease, and to that all our energies were directed. Theories founded on imperfect generalization could not be adopted in medicine with as little injury as in other sciences. It was of no consequence to the student of optics whether the modulatory theory of light was true or false, or to the astronomer whether the Copernican system was capable of mathematical demonstration; but it was of great moment to the physician as to whether alcohol was a food or merely a stimulant—whether it was entirely or in part, or not at all, consumed in the body—and still contradictory statements of that kind had been propounded for the last twenty years in succession, each professedly founded on experiments. In that instance, as in many others, error passed by a species of exomose to the general public, who adopted the views more agreeable to the senses, believing alcohol to be indispensable for the cure of all diseases, and for sustaining bodily health and mental energy. Happily, the timely declaration of 260 of the most eminent London physicians—which might be printed in letters of gold—placed the question on its true basis, stating that "while unable to abandon the use of alcohol in some diseases, no medical practitioner should prescribe it without a sense of grave responsibility, and with as much care as any powerful drug."

This and several other instances showed that, although practical men, they should bow to the declarations of science, and they should hesitate before accepting unfinished generalizations, which a fresh experiment or a newly ascertained fact might destroy. Even deductions derived from experiments on animals to test the effects of medicines on the living organisms, though of great value, must be received with a certain amount of caution—justified by the fact that certain deadly poisons for man were nutritive food to some animals; that zymotic diseases were not intercommunicable between men and animals, or rarely so; and that even age and idiosyncrasies modified the effects of medicines, so as to make it uncertain as to what might be the effects of a given medicine in one case by seeing its effects in another. Thus it could be seen that in the deliberations in the meetings of the sections there was a place for the purely practical as well as the scientific man. Their views test and are tested by each other. Rationalism enlightened empiricism, and enlightened empiricism was a check—a drag-chain on hasty theorizing—from which medicine had suffered so much injury through its whole history.

Whatever differences there might be in the expression of our views about treatment, or whatever disputes about theories, when we met disease in a con-

crete form in a fellow-man appealing to us for help, minor distinctions disappeared, and we found we had been differing in words, not in substance, and as happened in cities, from frequent consultations, there was a levelling of extreme views, and an unwritten practice of medicine became established. The chaff was scattered to the winds, and solid truth remained. "*Opinionem commentu delet dies; nature judicia confirmat.*"

Whatever drawback the physician might feel on the pride and satisfaction which ought to attend the practice of his profession, there was none from the study of hygiene and the enforcement of its principles or governments, corporations, and the general public. Here he was the more than disinterested servant of humanity, elevated far above the ordinary pursuits of professional life.

The address closed with the hope that when returning to their homes, all would be endowed with renewed devotion to the advancement of our great profession and the welfare of its members.

ANNUAL REPORT.

DR. ALFRED CARPENTER, President of the Council, read the annual report, which showed that the number of members admitted during the past year was 650; the number of deaths, 87; the number of resignations, 172; leaving the total number of members at 7,810.

The financial report showed a balance in favor of the Association of £768.

The report, together with the financial statement for the year ending December 31, 1878, was received, adopted, and ordered entered on the minutes.

The Association then adjourned, to meet on Wednesday, August 6th, at 11 A.M.

WEDNESDAY, AUGUST 6TH—SECOND DAY.

The Association was called to order at 11 A.M. by the President, Dr. O'Connor.

The only lady member of the Association, Mrs. Garret Anderson, was in attendance.

DR. ALFRED CARPENTER, President of the Council, announced the Committee of Council for the ensuing year, 1879-'80, as follows:

T. Clifford Allbutt, M.D., Leeds; J. T. Arlidge, M.D., Newcastle-under-Lyme; L. Borchardt, M.D., Manchester; J. B. Bradbury, M.D., Cambridge; G. W. Cullender, Esq., F.R.S., London; B. Foster, M.D., Birmingham; E. Long Fox, M.D., Clifton; Arthur Jackson, Esq., Sheffield; C. E. Lyster, M.D., Liverpool; F. E. Manby, Esq., Wolverhampton; Frederick Mason, Esq., Bath; Edward Morris, M.D., Spalding; R. H. B. Nicholson, Esq., Hull; G. H. Philipson, M.D., Newcastle-on-Tyne; T. L. Rogers, M.D., Rainhill; E. H. Sieveking, M.D., London; Henry Stear, Esq., Saffron Walden; A. P. Steward, M.D., London; W. F. Wade, F.R.C.P., Birmingham; C. G. Wheelhouse, Esq., Leeds.

DR. CARPENTER then proposed that the annual meeting for the year 1880 be held at Cambridge, and that Professor Humphrey be appointed President.

The report and the proposition made by Dr. Carpenter were seconded by Dr. W. D. Husband, and then unanimously adopted.

ADDRESS ON MEDICINE.

DR. ALFRED HUDSON, Regius Professor of Physic in the University of Dublin, then read an address on

medicine, in which he reviewed the earlier history of medical progress, and dwelt at length on the work done by the celebrated physician Laennec. He alluded to the discovery of auscultation by Auenbrugger, and mentioned that the idea of the stethoscope was suggested to Laennec Golsewing by some children playing in Paris—holding their ears at opposite ends of a beam of wood, and conveying from one to the other the sound produced by tapping on one end. Laennec was not slow in turning what he observed to practical account, and the result was the discovery of the stethoscope. He was afterwards enabled by means of this instrument to arrive at correct ideas with regard to the nature of the severest chest diseases, as well as disease of the heart. Dr. Hudson proceeded to describe in detail the views held by Laennec, and contrasted them with those of more modern observers, especially Niemeyer, whose views on pulmonary consumption were at variance with those of Laennec, and in which no one, however, could deny there was a great deal of truth. The address closed with a touching reference to the great loss recently sustained by the Association and by the profession in the death of Dr. Charles Murchison, whose life-work presented some analogies to that of Laennec. Like him, Murchison had left an imperishable memorial in his classical work on the continued fevers of Great Britain.

At the close of the address, DR. ANDREW CLARKE said, whether he looked upon the plan of the address or the manner of its execution; whether he regarded the felicities of its language or its fertility of illustration; its philosophy or discriminative minuteness; its unpretending wisdom, and its most charming simplicity—he saw equal grounds for congratulating both the speaker and the Association, and offered the following resolution:

Resolved, "That the thanks of this Association are due and are hereby given to Dr. Hudson, for his able and interesting address on medicine."

The resolution was seconded by Dr. Ringrose Atkins, sustained by the President in complimentary remarks, and unanimously adopted by the Association.

PRESENTATION TO THE LIBRARY OF QUEEN'S COLLEGE.

DR. T. GALLARD, of Paris, presented to the Association a number of his works, which were subsequently presented to the library of Queen's College.

The Association then adjourned, to meet on Thursday, August 7th, at 11 A.M.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 25, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

REPORT FROM THE MICROSCOPICAL COMMITTEE.

DR. W. M. CARPENTER presented the following report from the Microscopical Committee:

The larynx presented by Dr. Beverley Robinson, at a stated meeting held May 14, 1879, was found to contain the normal structures of the organ and a moderate infiltration of lymphoid cells. It did not contain miliary tubercles. The specimen of spina bifida presented by Dr. J. Lewis Smith, at the same stated meeting, was referred by the Committee to Dr. R. W. Amidon, who reported that it had decayed to

such an extent as to render microscopical examination impossible.

[Signed]

W. M. CARPENTER,
T. E. SATTERTHWAITE.

PERFORATING ULCER OF THE ANTERIOR WALL OF THE STOMACH, NEAR THE PYLORUS.

DR. F. V. WHITE presented a perforating ulcer of the stomach, with the following history:

M. D., a female, aged twenty-five, native of Ireland; twenty years resident in this country; her occupation, hair-dresser; of healthy ancestry. She had excellent health to her thirteenth year, when she had intermittent fever. Her health was variable, being chlorotic to her sixteenth year, when her catamenia were established. Her appetite was peculiar since the fever, particularly desiring sweets, cloves, and black pepper, using the latter even in her tea. When she was eighteen years old she had an attack of peritonitis, I should infer from the history. She had periods of indigestion, particularly in the spring and fall; she had a very severe attack last summer. Her teeth commenced to decay in her fifteenth year; four years ago what remained of her teeth were extracted, and were replaced by an artificial set.

I was summoned to her January 16th last (her family physician was sick), about 7 o'clock A.M. I found her in a semi-recumbent position on her right side, anxious expression of countenance, pale, cold perspiration, gasping, catching respiration, complaining of excruciating pain about the region of the diaphragm reflected to the clavicles. She was almost pulseless. On examination of the chest, discovered nothing acute; on palpation of the abdomen, no tenderness.

On the day previous to her attack she attended the funeral of an intimate friend, but did not go to the grave; in the evening she took a bath, washing her hair, and drying it before the parlor grate-fire. I was also informed she was in unusually exuberant spirits that evening. About midnight she was taken with excruciating pain in the epigastric region, and vomited. As she had had attacks previously, and, after using domestic remedies, was relieved, the relatives were not very anxious. On inquiring as to the character of the vomiting, was told there was no blood; that she had never vomited blood in her previous attacks.

My diagnosis was diaphragmatic pleurisy, based upon the following facts: the very inclement weather, snowing and cold; her depression on account of the fatal illness of her friend; the indiscretion of the bath, and washing her hair and drying it before the open grate-fire, exposing herself to a draught that cold evening. My treatment consisted in means to relieve the collapse, vomiting, and pain.

On my visit about 10 A.M. I found her markedly improved, vomiting stopped, pain somewhat easier. Continued the treatment, with the request, if fever set in, to stop it.

On my visit, 2 P.M., found her in a lower collapse than on my first visit. On palpation of the abdomen, found tenderness in the lower portion of the abdomen. I remained with her about two hours, treating her case as indicated. Being called to an urgent case of threatened pneumonia, I left her in a more comfortable condition, about 4 P.M. On my return, about 5 P.M., I was told she suddenly died about 4½ o'clock.

My opinion was that acute pleurisy, attacking her in so vital a situation in her depressed condition, was the cause of her death.

After considerable persuasion, an autopsy was per-

mitted, which was made about twenty-two hours after death.

On opening the abdominal cavity there was found general peritonitis, old and recent; there were old adhesions of the liver to the diaphragm; the posterior wall of the stomach was adherent to its surroundings; the stomach was found with an anterior perforation towards the pylorus; the usual contents and conditions, the result of the perforation, were found in the abdominal cavity.

The heart was normal; old pleuritic adhesions were found about the upper lobes of both lungs, especially the right; there was rather more than the usual fluid in the pleural cavity; no marked indication otherwise of pleurisy at the base of the lungs.

In the above history the following might be worthy of consideration: what effect the intermittent fever had, also the amenorrhœa in the causation of ulcers of the stomach.

An apology might be offered for my error in diagnosis by the obscurity surrounding these cases, as may be found without consulting further than the transactions of this Society, 1st vol., in the part devoted to perforating ulcers of the stomach."

(To be continued.)

Correspondence.

NOTE ON THE CAUSE OF SUDDEN DEATH DURING THE OPERATION OF THORACENTESIS.

REPLY TO DR. M. PUTNAM-JACOBI.

[TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Any one who criticises in print the remarks of another should, while doing it, give an accurate statement of those remarks, or, at least, of the evident purport of them. By none of my remarks, at a recent meeting* of the Pathological Society upon sudden pulmonary œdema, did I suggest that it was an accident which might occur *during* the operation of thoracentesis.

What I *did* say was as follows: "From the foregoing history and the morbid lesions revealed at the autopsy, I wish to draw an analogy between this case of ambulatory pneumonic consolidation with chronic pleurisy of the right lung, followed by very rapid and intense generalized œdema and congestion of the entire *left* lung, and resulting in a speedy death, and those instances of sudden œdema of a relatively healthy lung which occasion death *after* the operation of thoracentesis for large fluid effusions of the pleura." And, farther on, I *said* "that I presented the specimen chiefly because of its interest in one point of view: it enabled us to draw an analogy between the cases of sudden death *after* thoracentesis from pleurisy, and sudden death from œdema of healthy lung in a case of pneumonia."

Dr. Putnam-Jacobi, continuing her letter, writes: "It seems to me unnecessary to suggest *possible* causes for sudden death under these circumstances, when the cause is so obvious." In the first place, sudden œdema of a lung, after the operation of thoracentesis, is not a mere *possible* cause of sudden death. It is an actual

* See minutes of May 14th.

and efficient cause of sudden death; and to prove this, I can but refer my able interlocutor to my paper entitled "On Some Conditions, Physical and Rational, in Effusions of the Pleura, etc.,"* where the following statements can be found: "In a case reported by Dr. Ernest Legendre (*Gaz. des Hôpitaux*, 1875), fifteen days after the beginning of an attack of acute pleurisy, thoracentesis was performed and about three litres of fluid withdrawn. In a very short time after the operation dyspnoea recurred, copious secretion into the air-passages took place, cyanosis appeared, and death resulted from asphyxia in a few moments. The asphyxic state was occasioned here, no doubt, by *rapid and overwhelming bronchial effusion* . . .

Mr. Tenneson (*Union Médicale*, Feb. 22, 1876) relates a very similar case to that of Legendre's, where dangerous asphyxia took place after twenty ounces of liquid had been removed. These facts are corroborated by others mentioned by Behier, Liouville, and Terrillon (*Thèse de Paris*, 1873), all of which prove that death has occurred from the pulmonary congestion and œdema induced by too rapidly and thoroughly evacuating the thoracic cavity."

The obvious cause, reached by somewhat intricate reasoning, Dr. Putnam-Jacobi presents to her readers in the following words, textually cited: "When the operation has freed the thorax from the effusion which may have held one of its sides motionless, and the chest-walls begin to expand, they draw not only on the compressed lung, but on the heart, tending by 'negative pressure' to arrest its action in diastole. This tendency is not resisted as effectively as in physiological conditions, because by morbid habit the physiological reserve of force in the excito-motor ganglia has been reduced. If the reduction has fallen below a certain minimum, or if the cardiac muscle is degenerated, or if the expansion of the liberated chest-walls be sudden, syncope, or diastolic arrest of the heart is almost inevitable. It is again only a question of degree whether such arrest shall prove permanent, *i. e.*, fatal."

For the solution of "the obvious cause" to be supplied with three successive "ifs," appears to me "unnecessary." Moreover, there is nothing at all new in the conclusion arrived at by Dr. Putnam-Jacobi, as will be remarked, not merely by a reference to a "case in the *Am. Jour. Med. Sciences* for April, 1879," but also by reading the following lines which are cited from my own paper, previously mentioned: "There is a numerous class of cases in which a suddenly fatal termination, probably due to syncope, has occurred. Such an one is that of Legroux, where the patient, on admission into the hospital, presented an immense effusion. The thoracic cavity was completely evacuated by the use of the aspirator, and three-fourths of an hour afterward the patient died. . . ."

"Again, the mere pain of the puncture has been considered sufficient to arrest the heart-beats by reflex action. The case reported by Besnier is one in point. These lines are quoted from his article previously published.

Here the liquid was slowly withdrawn by a trocar No. 2, of Mathieu's apparatus, and with almost an excess of every precaution. But a few moments elapsed after the puncture, and only ten ounces of fluid had penetrated the receiving-bottle, when suddenly the patient became frightfully pale, and was found to be without movement and pulseless. . . . it soon became evident the woman was dead. In this and analogous instances I can only admit the sufficiency

of the apparent "cause of death, where there is great failure of heart-power. This may exist, as we know, even though the heart is not in its exterior aspect seriously affected, or, at worst, is somewhat enlarged and lœcid. Such cases are frequently encountered in other depressing diseases, owing to loss of nerve-force generated in the *cardiac motor centres*, rather than to the lack of tonicity in the muscular fibres," etc., etc.

Yours respectfully,

BEVERLEY ROBINSON, M.D.

NEW YORK, August 11, 1879.

NOTE ON THE CAUSE OF SUDDEN DEATH DURING THE OPERATION OF THORACENTESIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—We have read the "Note on the Cause of Sudden Death during the Operation of Thoracentesis," by M. Putnam-Jacobi, M.D., in the RECORD of August 9, 1879, with much interest. It seems to us that the doctor has hit rather wide of the mark.

The effect of expanding the chest during inspiration is to create a partial vacuum in all its cavities. In the bronchial tubes and air-vesicles the air is rarefied. In the heart and blood-vessels the gaseous constituents of the blood, relieved of pressure, expand. The diminished pressure in the bronchi causes a rushing in of air from the outside through the larynx until the atmospheric pressure is brought to an equilibrium. In the heart this expansion of gases causes probably a slight increase in volume of the cardiac contents, and therefore a very slight increase of opposition to cardiac contraction, which lasts till all vacuum is filled by the rushing in of air (see above) and of blood (see below). The atmospheric pressure, acting on the veins outside of the chest, presses the blood in them forward to distend the intra-thoracic veins and the right cavities of the heart, in which a partial vacuum has been caused ("aspiratory force" so called). When we aspirate a chestful of fluid we cause, in the pleural cavity, a partial vacuum. This the outside atmospheric pressure seeks to fill by the air rushing in through the larynx into the collapsed lung, by pressing forward the blood from the peripheral veins into the venæ cavae and right heart, and by pressing in the chest-wall. The chest-wall does not expand as a result of removing fluid *rapidly* by aspiration any more than it does as a result of removing fluid *slowly* by absorption. The two former processes are just what we have in normal respiration.

Suppose now that the aspiration is conducted too rapidly. The lung, long compressed by fluid and bound down by adhesions, expands imperfectly. The chest-wall is capable of collapsing only to a limited extent. The excess of the compensation falls obviously to the third factor. The venous blood is forced in great quantity into the right heart. Overdistention and paralysis of the right heart result. The patient suddenly expires.

This seems to us a sufficient and common-sense explanation of sudden death occurring during aspiration. It is hardly possible that the left heart has less work to do when one pleural cavity is filled with fluid. The right certainly has more, as it has to drive the greater bulk of the blood through a single lung, *i. e.*, it has to propel the same amount of blood as in health, but through a narrower channel. On the other

* THE MEDICAL RECORD, Feb. 3, 1877, p. 67.

hand, the left heart has possibly to contend against torsion of the aorta caused by cardiac displacement by the fluid. The sound side of the chest compensates by increased exertion for its disabled companion. So it seems to us that, so long as the patient is not cyanotic, we have no reason to suppose that the "negative pressure" is any less in a patient afflicted with pleuritic effusion than in a sound chest. In other words, the heart *as a whole* has probably more work to do in a patient such as we are considering than in a sound man. If it gives out at a trying moment, it is the result of overwork, *not* of lazy and improvident habits formed by ganglion cells during a period of diminished activity and suddenly called upon for a reserve force which they have foolishly neglected to provide. Yours respectfully,

R. VAN SANTVOORD, M.D.

66 WEST ELEVENTH STREET, AUG. 11, 1879.

CHOLERA IN JAPAN.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The cholera epidemic which has been raging for some time past in the southern provinces of this empire shows, by last accounts, but little signs of abatement.

The cities of Osaca and Hiogo are suffering most severely, the former reporting for June 4,174 cases and 3,115 deaths.

By a seven-days' detention system of quarantine, both by sea and land, the disease has been held back from the northern provinces and the capital up to date.

In addition to this, energetic sanitary measures are being adopted by all the municipalities of the northern towns in hopes of being able to retard, if not entirely escape, the scourge.

Two facts favor this possibility, viz.:

1. That a mountain range with only three passes separates this part of the country from the infected districts.

2. That a single line of steamers is the only regular means of communication between the cities referred to and this port and Tokio.

D. B. SIMMONS, M.D.,

Health Officer for the Japanese Government for the Ports of Yokohama and Tokio.

YOKOHAMA, JAPAN, July 15, 1879.

JAPANESE PAPER ICE-BAG.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The accompanying sample of *paper ice-bag* I regard not only as a curiosity in its way, but find it very useful. I have employed no other in my hospital for some year or two for applying ice as a therapeutic agent. It is good for several days' constant use, hence sufficiently long for any ordinary case in which it may be required, when its cheapness allows of its being thrown away. As far as I know it is a purely Japanese invention, and adds one more to the almost innumerable uses to which they put paper. I may say they also make water-beds, cushions, etc., in the same manner.

Respectfully yours,
D. B. SIMMONS, M.D.,
Surgeon to Kerr Hospital.

YOKOHAMA, JAPAN.

New Instruments.

A NEW FORM OF PNEUMATIC APPARATUS—OF CONTINUOUS ACTION AND GREAT PORTABILITY.

THE treatment of certain diseases of the respiratory and pulmonary organs with rarefied and condensed air has become firmly established. If it has not been resorted to as frequently as successes attained by it would appear to warrant, this is due partly to inefficiency of many apparatuses devised for the production of rarefied and condensed air, and partly to difficulty in their manipulation. The requirements which an apparatus for the purpose named should fill, are facility of manipulation and provision for the steady maintenance of about the desired degree of rarefaction or condensation.

Until recently the well-known Waldenburg's apparatus has filled these indications better than any other; yet the manipulation of its weights is very troublesome, and sufficient to deter many from its use. Besides, the objection is made against it that it consists of so many parts loosely united as to make it generally lacking in solidity.

To evade all these objections a new apparatus has been devised for the production of rarefied and condensed air, which fairly has the prospect of coming into general use. The annexed figure (1) illustrates it;

FIG. 1.

and one of its principal features, the crank, can readily be perceived, by the mere turning of which, rarefied or condensed air can be produced. The rudimentary ideas for the construction of this apparatus have been given by Professors Mayr and Geigel, of Würzburg, and their realization has been afforded by Dr. Hess.

The apparatus is constructed upon the principle of the "Bucket-wheel Blower" (Schöpfradgebläse), of which the diagrams, Figs. 2 and 3, will give an idea. M, Mr, M, is to illustrate an enclosure similar in shape to the glass covers over parlor clocks, made of strong sheet iron. This enclosure communicates with the outside air by the opening and outlet Mr, and contains perpendicularly the "bucket-wheel," shown in

the diagram by the double circle, divided into twelve equal parts. The horizontal axis of the bucket-wheel rests in the centre of the enclosure and projects on the outside, where a cog-wheel and crank can be applied, and the wheel thereby easily revolved. Axle, spokes, cog-wheel, and crank are not shown in the diagrams 2 and 3.

FIG. 2.

will then enter the bell. By closing the upper opening Gr the air will accumulate more and more in the bell space; thereby the level of the water in the bell-space is lowered, and is raised in the enclosure by the water passing through the opening, G G.

In this manner the increasing quantity of air in the bell-space will gradually assume its water level down

FIG. 3.

The bucket-wheel, which is also made of sheet iron, has on its inner concave side (towards the middle) empty buckets (Fig. 2, C 1, 2, 3, . . . 12), which, imagining that it were revolved to the right, have at their front surfaces, towards the middle, small slit-shaped openings, the opening on Z being near m on Figure 2. Through these openings each bucket communicates with the space within the enclosure. Now if the enclosure is filled through the opening Mr with water to the height of WW, and the bucket-wheel revolved to the right, the air-filled buckets 3, 2, 1, 12, etc., will descend below its level. The air contained in every one of these buckets will be somewhat compressed by the water entering as much as possible into the bucket openings, carried further by progressing rotation. The bucket-mouth is directed to the top, when the air will escape in the form of bubbles rising through the water. It can be readily understood from Fig. 2 that the escape of air from the buckets goes on while the buckets, during rotation, take the positions which the buckets 5, 6, 7, 8 are shown to have. In the same degree these buckets will be filled with water, which they carry until their mouths reach the position of bucket 11. Bucket 2 will already be filled entirely with air, and when reaching the position of bucket 3, this entire process repeats itself.

Suppose, now, that a bell is inserted inside of the bucket-wheel, resting in the flat, cylindrical enclosure. This bell has two openings, a wider, lower one (G G, in Fig. 3), reaching considerably under the water level, and an upper, narrow one, passing through the enclosure, and thereby in communication with the outside air. Self-evidently the upper part of the bell, its outlet, must be of such a form that the bucket-wheel can be rotated without obstruction and without interfering with space within the bell.

It can be readily seen that the lower margin of the bell is well over the lowermost situated buckets. If the bucket-wheel is turned to the right, the buckets filled with air, 3, 2, 1, etc., will pass the lower mouth of the bell, G G, and allow the air to escape, which

to W_1 , W_1 , while at the same time the water level in the enclosure will rise to W_2 , W_2 .

The difference between these two water levels indicates the atmospheric pressure bearing upon the air in the bell space, or the degree of tension produced by a water column whose height is equal to it.

Upon opening the outlet Gr, the air will rush out. However, as a sufficient velocity of rotation of the bucket-wheel will constantly supply the bell-space with as much air as escapes, the amount of atmospheric pressure in the bell, even when its opening is not closed, can be steadily maintained to any degree desired.

(1). In this condition the apparatus is arranged for inhalation of condensed air; the rotating of the crank causes accumulation or condensation of air in the bell space, which may be conducted into the lungs through a tube, Gr, ending in a mask.

If, on the other hand, the opening of the enclosure Mr is closed, while the opening of the bell-space Gr remains open, and the bucket-wheel rotated in the same direction as before, air will be drawn from the enclosure and brought into the bell-space. This will produce rarefaction of air in the enclosure, following which the water level will rise in the enclosure while it sinks in the bell-space. As in case of condensation of air in the bell-space, the rarefaction in the enclosure increases in proportion to difference in height of the water levels. After opening Mr, the rarefaction may be constantly maintained if the velocity of rotation of the bucket-wheel, or the transport of air out of the enclosure, is analogous to the quantity of air entering through Mr.

(2). In this condition the apparatus is adapted for exhaling into the enclosure, by connecting it with the lungs by the mask, tubing, and outlet Mr. From this elementary description of the apparatus one can conclude that its mechanical productiveness or efficiency is dependent upon its size.

The apparatus is provided with an improved man-

ometer, registering by red-colored water, which is more readily visible and more sensitive than mercury. Masks and stopcocks are of an improved pattern on the Waldenburg apparatus.

The latter and above described new form of pneumatic apparatus are manufactured by Messrs. J. Reynders & Co., of No. 303 Fourth Avenue, New York.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 10 to August 16, 1879.

FORWOOD, W. H., Major and Surgeon, McPherson Barracks, Atlanta, Ga. Granted leave of absence for one month, with permission to apply for two months' extension. S. O. 123, Dept. of South, August 13, 1879.

HORTON, S. M., Major and Surgeon. Granted leave of absence for two months. S. O. 42, Div. of the Atlantic, August 12, 1879.

GIRARD, J. B., Capt. and Asst. Surgeon, Ft. Davis, Texas. Granted leave of absence for one month on surgeon's certificate of disability, with permission to leave limits of the Department. S. O. 168, Dept. of Texas, August 8, 1879.

KIMBALL, J. C., Capt. and Asst. Surgeon. Granted leave of absence for fifteen days. S. O. 40, Div. of the Atlantic, August 9, 1879.

MOFFATT, P., Capt. and Asst. Surgeon. Assigned to duty at the new post in the vicinity of Lake Cheilan, W. T., to which post he will proceed at end of current month. S. O. 96, Dept. of the Columbia, July 28, 1879.

BANISTER, J. M., 1st Lieutenant and Asst. Surgeon. Having reported in person, ordered to report to C. O., Ft. Leavenworth, Kans., for temporary duty. S. O. 151, Dept. of the Missouri, August 7, 1879.

CARTER, W. F., 1st Lieut. and Asst. Surgeon, now at San Antonio, Texas. To proceed to Ft. Concho, Texas, and report to the C. O., District of the Pecos, for duty in that District. S. O. 164, Dept. of Texas, August 4, 1879.

FITZGERALD, J. A., Capt. and Asst. Surgeon, died at Columbia, Pa., August 11, 1879.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 16, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.

Aug. 16, 1879.	10	18	37	4	28	14	5	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from Aug. 13th to 18th inclusive was 158, and the number of deaths that occurred was 52. The total number of cases for this year to Aug. 19th is 575, and the total number of deaths 158.

During the past week two new cases have been sent to the Quarantine Hospital in this port [New York].

MEDICAL DEPARTMENT OF YALE COLLEGE.—In accordance with a long-cherished plan, the Medical Department of Yale College announces a graded course of instruction extending over three years. Preliminary examinations are required for admission, except from those who present a degree in Letters or Science, or have passed an examination for admission to Yale College or some similar institution, and are conducted in writing. Examinations, chiefly in writing, will be held at the end of each year to determine the standing of students with reference to their advancement to the studies of the succeeding year.

AMPHORIC RESPIRATION.—Dr. M. L. James, President of the Richmond Academy of Medicine, expresses the opinion that adhesion of the pleural surface of a cavity with the chest-wall is the usual condition by which amphoric respiration is produced. Authorities recognize the existence of a large cavity with firm walls as the occasion of amphoric respiration; but he has nowhere seen any reference to pleural adhesions as the particular condition by which those walls are made thus firm.—*Southern Clinic*.

THE ARMY MEDICAL SERVICE of Great Britain appears to be in a very unsatisfactory condition. During a debate on the subject at a recent session of Parliament it was acknowledged that there were more vacancies than applicants for positions in the service, and that it was indeed the only branch of the public service in which such a state of affairs existed. Physicians do not care to become army surgeons. Such a state of affairs is remarkably different from that in our own country.

THE EFFECT OF SMOKING UPON THE TEETH.—In a paper read by Mr. Hepburn before the Odontological Society of Great Britain it was claimed that smoking was beneficial to the teeth. The alkalinity of the smoke neutralizes any acid secretion there may be in the mouth, and the antiseptic property of the nicotine tends to arrest any putrefactive change in carious cavities. Tobacco will only discolor teeth when there is a crack in or loss of the enamel.—*British Medical Journal*.

VAGINO-CERVIPLASTY ;

OR, SHORTENING OF THE CERVIX UTERI BY TISSUE-
SLIDING.

A LECTURE DELIVERED

By MONTROSE A. PALLEN, A.M., M.D.,

PROFESSOR OF GYNECOLOGY AT THE MEDICAL DEPARTMENT OF THE
UNIVERSITY OF THE CITY OF NEW YORK, APRIL 24, 1879.

(Reported for THE MEDICAL RECORD.)

GENTLEMEN:—By reference to the *Records of the Clinique* for April 3d, we read about the patient presented to you to-day, as follows :

"*Mrs. Cummings; married; aet. 26; Ireland.* She has always menstruated regularly, and has no pain, except on the first day. No menorrhagia, no leucorrhœa; nor is there any bladder or rectal trouble. The pelvic contents are remarkably free from inflammatory products, if we are to judge from her subjective history. She has been married three years, but has borne no children, and she comes here to discover if there is any cause and remedy for her dyspareunia and sterility.

"*Digital examination* reveals the cervix uteri very much elongated and flattened from before backward. *Conjoined manipulation* develops a well-defined ante-flexion of the cervix, and a moderate degree of corporeal ante-curvature likewise, evidently produced by pressure of the superincumbent viscera.

"By means of the *speculum investigation*, actual measurement of the intra-vaginal cervix displays a length of 1½ inches posteriorly, and 1½ inches anteriorly. The sound penetrates to the fundus uteri, and marks 2½ inches of depth.

"*Diagnosis.*—Prof. Pallen regards this condition as one of normal uterine development as to length, both in body and neck, but defines the lesion to be an *apparent (not real) elongation of the neck of the womb, in consequence of faulty implantation of the vagina.*

"*Treatment.*—Surgical procedure is advised, whereby the neck of the womb can be relatively shortened by sliding the vaginal mucous membrane downward, and lifting the neck into an artificial sheath.

"*April 10th.*—Patient was placed under ether and brought into the amphitheatre. Vagino-cervioplasty was made by stripping the upper portion of the mucous membrane from the circumference of the cervix to the width of about six-sevenths of an inch anteriorly and five-sevenths posteriorly, together with a dissection of the mucous membrane above, from around the junction of the body and neck, without ablating it. The neck was then slid into the new socket or sheath thus made, and the margins united by nine silk sutures. There was considerable hemorrhage, as a good-sized artery (possibly the abnormally distributed circular) was severed in the denudation. The bleeding was, however, checked by torsion at either extremity of the vessel. Prof. Pallen's modification of the Sims speculum was used, because it gave greater space."

After the operation the patient was removed to her home in a carriage, and Drs. Van Ramdohr and Norris watched her carefully. It is useless to follow the daily history of the case, inasmuch as the wound made a speedy union, and again our patient presents herself fourteen days from the date of the operation. A speculum examination reveals the cervix uteri lifted from its

former resting-place upon the perineum, and its flattened appearance is gone. The ante-flexure of the body is likewise less, because the uterus is no longer squeezed between the abdominal contents above and the perineum below. The sound penetrates with less bending, and marks a depth of 2½ inches. The sexual organs are nearly normal as far as place is concerned, and we can safely anticipate a painless, and possibly a fruitful coition in the future. With such a cervix as this patient had prior to the operation, almost protruding from the vulva, conception was not to be considered, nor did she ever submit to the marital congress except to frequently feel distress, which occasionally amounted to actual pain.

This is the fifth case of the kind upon which I have operated. The first three operations were reported to the *Obstetrical Society* in October, 1874, and subsequently published in the *Journal of Obstetrics*, February, 1875. The fourth case was operated upon in February, 1878. Without entering into the histories of these cases, let me call your attention to certain facts in embryology, and the much-neglected study of teratology, viz., the science and philosophy of monstrosities. This preliminary study of embryological and teratological facts will give you an idea why this operation was conceived, and you will be pleased to learn how much every department of surgery and applied pathology can be more than substantially benefited by a careful exploration of the development and growth of organs.

An arrest of embryonic development, a fixation or stoppage of a perfectly normal transitory state, or a failure and arrest of the second pubertic development, may and does result in a permanent anomaly materially affecting the future of the generative organs. If the converse of this take place, it is equally productive of harm, because an excessive developmental impetus results in increased growth, and determines an increase in one or more of the organs designed for copulation, generation, or parturition. If these propositions were not true, how then could we explain the presence of a double uterus and vagina, or a double vagina and single uterus, or the absence of a vagina with a rudimentary uterus and well-developed ovaries, and many other conditions indicative of arrested or excessive embryogenic impetus. No condition of embryogenic life persists after birth unless there has been arrest of some transitory state, as in this patient with apparent elongated cervix; she has grown to womanhood with certain arrested formative actions of the hollowing out of a membranous spur, given off from the Wolffian bodies, somewhere about the eighth or ninth week of gestation.

So positive are the interconnections, anatomical and physiological, of the vagina, bladder, rectum, uterus, oviducts and ovaries, that the harmony of their correlations cannot be disturbed without portentous trouble. Thus, too small a vagina, too large a bladder, too low a uterus, or too contracted a vulva, may develop dyspareunia (painful coition); an infantile uterus, or the persistence of prepubertic ante-flexion, or too narrow a cervical canal may produce (and generally does) dysmenorrhœa; the conditions of dystocia or the causes of sterility are likewise frequently traceable to arrested embryogenic development, or may be induced by infantile and prepubertic pathogenesis. However interesting these points may be, I must, for the present, defer their elaboration to a consideration of the development and functions of the vagina, as well as its abnormal implantations, in order to explain upon what exact grounds vagino-cervioplasty was performed on Mrs. Cummings, and

why I deemed the operation feasible long before I had experience enough to sustain these preconceived ideas. Now let us study the structure and objects of the vagina. In the embryo, the vagina is an organ of mixed formation, intermediate in function and position, and is produced by the cleavage or hollowing out of a membranous spur—a true cloacal septum—between the bladder and rectum. This process occurs about eight weeks after conception, when the uterine and vaginal cavities are one and continuous. About the fifth month these two organs are materially distinct, and, if no arrest of development has taken place, or no increased formative action been manifested, the implantation of the vagina upon the cervix (what is known as “histological fusion”) will be of that character denominated healthy or normal, so that when the girl reaches puberty, the angulation at the junction of cervix and vagina will be about 155°, and the correlations of place perfectly symmetrical.

In the perfect woman, the vagina is fused normally to the cervix higher upon the posterior than upon the anterior surfaces. Posteriorly it is reflected upon itself, and its upper or pelvic extremity is convex and in juxtaposition with that fold of the peritoneum known as Douglas's pouch. Anteriorly, but on a lower plane, it is attached to the cervix behind and to the bladder in front, and sends processes or duplicatures in a horizontal direction, without dipping or folding upon itself, as in the posterior fornix. In totality, the vagina is an inverted cone, with a greater amount of ballooning posteriorly than anteriorly. The sustentative functions of the vagina depend upon its surrounding connective tissue, as well as its attachments to the pelvic fasciæ from and around the bladder (the pubo-vesico-uterine ligaments of Hyrtl), and the dissepiments and processes of musculo-serous tissue attached to the sacro-lumbar ligaments. When no increase, either of vascular, muscular, or connective tissue takes place, the *vagino-cervical fusions are mutually sustentative and supporting, and it is only when the correlation of place and order is destroyed by pathogenetic causes that we are called upon to treat post-pubertic lesions and congenital or teratological abnormalities.*

Normally, the intravaginal portion of the cervix uteri in the average-sized nulliparous woman has a dip of about half an inch, and in parous women somewhat less, but with a corresponding increase in length in the supravaginal portion, the isthmus, and the fundus. The depth from the os externum to the fundus of the nulliparous woman during the intermenstrual period is a fraction over two and a half inches, and something less than three inches in mothers. Any marked increase beyond these measurements is indicative of hypertrophic elongation of the cervix, subinvolution of the entire organ, the presence of a neoplasm or hyperplastic formations. In the patient before us, the persistence of the normal measurements in totality, notwithstanding an excessive elongation of the intravaginal cervix, indicated a faulty implantation of the vagina, and not a hypertrophic elongation of the cervix. The treatment of such a case prior to 1870, consisted in ablation, either by the knife, the *écraseur*, or the galvano-cantery, of half or three-quarters of an inch of the elongated neck. *Such amputations I deem to be mutilations, when the entire length of the cervical and corporeal cavities do not exceed three inches.* Amputations of the neck of the uterus, particularly by the *écraseur*, are fraught with great danger, and quite a number have been recorded where the peritoneal cavity has been opened. Mark

you, I do not advise you never to amputate the neck of the uterus, but not to amputate such cases as this presented to you to-day.

There is another anomaly of defective cervico-vaginal dimension, the very converse of the subject under consideration, and it consists of an implantation or fusion of the vagina too low down upon the cervix, giving it an intravaginal dip of hardly more than the sixth of an inch. I would not call this an “infantile neck,” as it is described in the books, because the *true* infantile neck is relatively greater in size and development than is the uterine body. For this condition no method of treatment has as yet been devised; possibly a plastic sliding of the vagina upward, the converse of what you saw me do in vagino-cervioplasty, may be successfully made, whereby the superior edges of the circumsection may be “hemmed” down to the cervical tissue proper, and the intervening spaces filled up with granulations. Vagino-cervioplasty is applicable to those cases *where*

FIG. 1.—A. Abnormal implantation of the vagina producing intravaginal elongation of the cervix. B. Normal vaginal implantation. This figure is given as illustrative of the mechanism of the lesion under consideration by comparison of the two conditions.

the longitudinal diameter of the utero-cervical cavity does not exceed three inches, but where the intravaginal portion of the cervix is so long as to interfere with either locomotion, sitting, coition, menstruation, or conception.

The most remarkable instance of excessive intravaginal elongation is reported by Martine (of Biberach), where the posterior fornix was attached to the fundus of the uterus. Ordinarily in this anomaly the fusion takes place on a level with the isthmus, about three-fourths of an inch too high, but not sufficiently high to invade the retro-uterine pouch (Douglas's cul-de-sac).

In performing the operation for vagino-cervioplasty, we must be careful to make our dissection to avoid a possible invasion of this peritoneal pouch, and for that reason the upper margin of denudation is sloped lower on the posterior wall of the cervix than on the anterior; and the inferior margin is likewise stripped lower on the posterior than on the anterior surface. This latter stripping is done for the purpose of equalizing the strain upon the stitches, so that when the

wound is drawn together it looks like a ring around the cervix pushed higher on the anterior than on the posterior wall.

To recapitulate: vagino-cervioplasty consists in a circumsection of the mucous membrane by means of a bistoury, with its cutting edge at right angles to the shank, and stripping it from the cervix to a point about three lines from its distal extremity anteriorly,

FIG. 2.—Showing the line of separation above the stripped cervical mucous membrane, and the position of the silver sutures before the sliding is perfected.

a little more than three lines posteriorly, and carrying the dissection upward for about an inch anteriorly, less than an inch posteriorly. This leaves nearly the whole of the vaginal portion denuded of its mucous covering. Ordinarily the hemorrhage is but slight, as no vessels of any magnitude are normally encountered.

The next step of the operation should not be commenced until all bleeding has ceased, as it is of the utmost importance to see each section of the sub-mucous connective tissue. The first incision is made with scissors curved on the flat, cutting with the concavity toward the cervical tissue; when a separation is made, a tenaculum is hooked into the mucous membrane, and the dissection is carried halfway around the cervix; the tenaculum is handed to an assistant, and another inserted into the undenuded mucous membrane, where the stripping was first commenced, and a similar separation is made on the opposite side until the first is met.

The depth of these incisions of separation varies from three to eight lines, according to the greater or less length of the cervix. Should a vessel of any magnitude be divided (as it was in this case), it must be torsioned or ligated at either orifice, for reasons well understood. Usually the bleeding has been controlled by sponging with cold alum-water. The silver wire (or carbolized-thymolized-silk suture) is then passed from above downward, from without inward on the upper flap, and from within outward on the lower flap. All sutures are inserted by means of the

"fish-hook" needle, trocar-pointed.* In my first operation I used very short, straight needles, half an inch in length, but they were not so conveniently passed as the fish-hook needles since used in all operations about the cervix uteri, or in either fornix of the vagina. When the sutures are all adjusted, three in front and four behind, the parts are drawn together, and the apparently elongated cervix is short-

FIG. 3.—Showing the adjustment of the flaps, and the appearance of the neck after vagino-cervioplasty.

ened by being covered by the reflected vagina; or, more accurately speaking, the cervix, deprived of its adherent mucous membrane, is drawn upward into the upper loosened sheath.

In all the five cases upon which I have operated, union has been complete and the sutures withdrawn on an average of about twelve days.

The treatment subsequent to vagino-cervioplasty consists in such cares as are rendered all patients after operative procedure upon the genital organs; such as horizontal posture, evacuation of the bladder (if necessary) every six hours, quiescence of the bowels, and sometimes the exhibition of opium.

Pelvic cellulitis, non-union of the wounds, inflammatory developments—in fact, any of the sequelae of pelvic surgery might supervene after vagino-cervioplasty as well as after any other operation about these parts; but they are infinitely less probable than if amputation of the cervix had been made. You saw the *modus operandi*, and I have entered again into its detailed description, so that you may fully appreciate the *modus faciendi*. Now you may ask why such an apparently tedious and intricate surgical procedure was done in this case, and in what conditions of the sexual apparatus would you be warranted to attempt it?

The patient presented herself here simply because of her sterility. She had no aches nor pains, save

* For more than fourteen years I have used "trocar-pointed" needles of all shapes, ground very short, and if any one will make the trial, it will be found that they are vastly superior to all other needles.

during marital congress; then she always had dyspareunia. This pain at coition is readily understood, because the vagina was relatively shortened and the uterus actually lower in the pelvis. Every intromission of the male organ not only stretched the vagina, but likewise impinged upon the dragged uterus.

Her sterility was clearly mechanical, because it was entirely out of the question to presume that the semen could be ejected into the canal of a cervix which lay parallel to the male organ whenever this latter was in the vagina. Ejaculation of the spermatozoa took place behind and above the cervix, high up in the posterior vaginal fornix; and unless the germinating fluid is thrown directly into the canal of the cervix, conception will not take place, however much the book-making physiologists may say to the contrary. If it were not intended for the semen to be propelled or thrown into the uterus, of what use are the ejaculator muscles? If the spermatozoa possess the so-called elective power of *crawling* down the cervix, over its inferior margin, into the canal, thence up into the uterus to hunt up the ovum, and there to embrace it, as an anaconda winds around its unsuspecting prey, why should the mechanics of erectility and motility be so superbly illustrated as in the central fixation of the uterus in the pelvis pending the loading of the venous trabeculae around the whole generative tract? Nature nowhere adapts ends without physical means. Conception never takes place unless the male germinating fluid encounters the female ovum in such a place where the placental tufts may thrive and grow. Never does the semen seek these spots unless it has been implanted there; it does not permeate the organism like a secretion!

Now this operation of vagino-cervioplasty was made for the purpose of allowing the implantation of the seminal fluid in the proper place. I have lengthened the vagina by relatively shortening the neck. The strain has been removed—that of dragging from below, as well as of pressure from above. If fruition should ensue, clearly it will be another fact illustrative of purely physical conditions, an establishment of the correlation of order and place, as productive of results hitherto regarded as a species of mysticism. The correction of defective physical relationships in the overcoming of sterility is worthy of the profoundest study, and numerous surgical procedures may be cited as evidence, and none more so than the plastic sliding of the vaginal mucous membrane in apparent elongation of the cervix.

NOTE.—July 14th.—This patient was exhibited to the New York Obstetrical Society in June. Then, as now, the result of the operation was most apparent. She was last seen on July 3d, and was free from dyspareunia. Her menstruation was due on July 6th, but she has not since reported.

The cervix uteri is not more than three-fourths of an inch in length, and is quite two inches from the vulvar orifice. The ante-curvature of the body of the uterus had very much diminished.

THE EXPECTANT TREATMENT OF CHOREA.—At the Radcliffe Infirmary, Oxford, a case of chorea was recently treated without medicine. The patient, a boy of ten, was placed in a well-padded crib and supplied with the most nutritious food. The symptoms were severe, and for ten days slightly increased in violence. On the tenth day a remarkable subsidence of the choreic movements took place, and from this time the child steadily improved. By the end of the tenth week from the beginning of the attack he was completely well. It is a curious fact that the duration of the disease thus left to itself was the same as that estimated by Hillier and See as the average duration under all kinds of medical treatment.—*Lancet*, July 5, 1879.

Original Communications.

CONTRIBUTIONS TO ORTHOPÆDIC SURGERY.

By CHAS. F. STILLMAN, M.D.,

PLAINFIELD, N. J. (CURATOR TO ST. FRANCIS'S HOSPITAL, N. Y.)

At a time when appliances for the relief of Pott's disease are becoming as varied as at present, and when it is desirable in so many instances to employ extension and expose diseased surface, I should fail in my duty to my profession did I refrain from drawing attention to a splint for these purposes, which is proving itself in my hands, and in the hands of many surgeons throughout the country, of the utmost service in producing these results.

In January, 1878, the writer originated the idea of using an apparatus embodying extension and fixation for Pott's disease of the spine, and in February, 1878, incorporated an article upon the subject in a pamphlet published by Geo. Tiemann & Co., of New York. I produced extension by means of a compound bracket, consisting of two overriding, slotted strips, connecting two terminal zinc perforated plates, imbedded in plaster-of-Paris above and below the seat of disease—and, so far as I have learned up to the present time, was the first to apply the apparatus. I soon found the plan impracticable, however, except in the first stages of disease, because the unequal lengthening or shortening of the extension strips would alter the position of the plaster-of-Paris attachment to the body, thus causing discomfort to

FIG. 1.

the patient. Pursuing my investigations, I have since found that keeping the extension-strips at right angles to the attachment, however great the deformity, by the addition of a modification of my slotted steel sector to each (see Fig. 1), and the use of an original combination, immovable dressing of adhesive plaster and plaster-of-Paris, starch, etc., enables the surgeon to obtain the fixation, extension, exposure, and gradual reduction of deformity which are the requisites of mechanical treatment, without disturbing the attachment to the body, or causing discomfort to the wearer

by its impingement upon one point of the surface more than another. The weight of the bracket is from six to ten ounces, the bridges and sectors of which are made from very strong and light crucible steel, so tempered at the incline that they may be bent to any angle with the terminal plates, which are made of thin, flexible copper, to enable close adjustment to the body; the whole being nickel-plated, to avoid rust (see Fig. 1).

APPLICATION.

Stand or seat the patient erectly, and apply strips of canton-flannel (or moleskin) adhesive plaster vertically around the entire waist, above and below the seat of disease, one-eighth to one-half inch being left uncovered between the strips. Next, encircle the two divisions of the waist transversely with long strips of the same material. We have now a strong adhesive-plaster base on the body to which to fasten the bracket. Next, sew two strips of the adhesive plaster, of sufficient length to more than encircle the body, to the terminal plates, as shown in Fig. 4, and bend the plates to conform accurately to the surface of the body.

After adjusting the bracket, with its bridge shortened as much as possible, and its clamps loosened, fasten it securely and tightly to the body by means of the adhesive plaster. Firmness and fixation are now given to the splint by rollers of starch or plaster-of-Paris bandage wound tightly over the whole, these uniting with the nap which covers the outside of the adhesive plaster, to form one immovable splint, which is firmly fastened to the skin over a large extent of surface, and yet conforms so accurately and immovably to the convexities of the pelvis and chest, that no amount of extension we may deem it necessary to employ can cause its displacement, if the sector be employed.

This combination of adhesive plaster and starch, plaster-of-Paris, silicate, or other immovable bandage, makes a much lighter attachment than plaster-of-Paris alone, adjusts itself to the body more accurately, and does not suffer the same amount of expansion and consequent loosening, while retaining the good qualities of firmness and fixation. (In several cases lately where I have thought it advisable to apply Sayre's plaster jacket, I have used this combination instead of the plaster alone, and in every case with congratulatory results.) A great advantage of this splint is the avoidance of any suspension apparatus during its application, and, consequently, the avoidance of cramped and painful positions; there being no necessity for undue haste, the clamps not being tightened necessarily until after the completion of the application.

This splint possesses all the advantages of the plaster jacket; but, in addition, we are enabled to straighten a patient while still keeping up extension, thus tending to keep weight off the diseased part, separating the opposed diseased surfaces, exposing the external surface for application and elastic compression, and fulfilling generally all the mechanical conditions necessary for the relief of vertebral disease. It is provided with a clamp-key, so that it can only be manipulated by the person in charge. The brace shown in Figs. 1 and 2 was used successfully in a case of Pott's disease in which the lateral curvature was a prominent feature. For posterior curvature the sector and slotted strips are placed antero-posteriorly.

HIP-JOINT.

Two objections against the use of any existing braces or other contrivances for the relief of inflamma-

tory conditions of this joint, are obviated by the use of my sector splint and combination attachment. These are: 1st, the perineal band with its chafing and discomfort; and 2d, the production of extension in only one position and subsequent ankylosis. For this pur-

FIG. 2.

pose the splint is used as a bracket (although the sector arrangement may be inserted into any brace). It consists of two terminal plates of thin copper—perforated upon the upper or plaster side—connected by a compound slotted bridge raised a short distance from the surface. This bridge consists of two over-

FIG. 3.

riding slotted steel strips, connected to a slotted steel sector by three clamps, as shown in Fig. 3.

These clamps may be operated either with a thumb-screw or key.

APPLICATION.

Strips of the canton-flannel adhesive plaster are fastened vertically around the waist and along the

thigh of the affected side, a space of one-eighth to one-half inch between, and then bound down by longer strips encircling them. The plates of the bracket are then sewed to two long strips of the adhesive plaster (see Fig. 4), which binds it down closely and unalterably to the limb.

FIG. 4.

In applying the bracket, care should be taken to have the central line of the strips and plates correspond to axes of the body and thigh, and the bridge shortened. It may be applied in any position of the limb. The bracket is now to be closely bound down to limb and waist by the thick, strong adhesive plaster (the bridge being in position over the joint), and only needs a few rollers of starch-silicate or plaster-of-Paris bandage wound around the plates to insure the firmness and fixation of the whole, cleanliness being effected by a dry muslin-bandage covering. (See Fig. 5.)

Every inflammatory condition of this joint—acute or subacute—whether arising from disease, injury, or operation, can be benefited by this simple splint; for by allowing the limb to be fixed in the most suitable position, and causing extension to be made in that position, diseased surfaces are separated, reparation encouraged, and the sufferings of the patient diminished. Passive motion may be employed as often as desired, the limb between such occasions being locked securely by the clamps in any position, and with any degree of extension, any induced or existing inflammation being combated by external applications, which are permitted by the exposure of surface allowed by the structure of the splint.

This splint is sufficiently powerful to effect a gradual reduction of deformity, ankylosis, etc., and with a very little degree of discomfort to the patient, as the fulcrum of the lever is in the bridge of the splint over the joint and not in the joint itself, the contiguous surfaces of which are previously drawn apart and retained so during and after the reduction. This process may be repeated as often as necessary, and in many cases will obviate the necessity for operation.

This splint in its various modifications may be used for all or any of the joints of the body, occupying for itself a new and unique field among surgical appliances, bearing the same relation to the knife in surgery that the bougie or gradual dilator does to the knife in the treatment of stricture of the urethra, doing away with its use in many cases, and when it is used, assisting

the knife, by placing the joint under the best possible condition for rapid, proper, and complete recovery. In morbus coxarius it is proving itself invaluable, and in connection with the crutches and the raised shoe (Hutchinson's method), fulfils every indication for treatment, although I have found the advantages

FIG. 5.

arising from the shoe not so important providing the crutches and the bracket were used. The use of the latter causes pain, startings of the limb, etc., to cease at once, and allows the patient to pursue out-door occupations. Among other recommendations of the splint may be mentioned:

- 1st. Utility—the uses for the splint being so varied.
- 2d. Simplicity.
- 3d. Durability.
- 4th. Cheapness.

One bridge can be used for any or all of the large joints of the body by means of removable attachments to terminal plates of assorted sizes. It may be used with any form of joint, brace, or attachment, the slotted strips and sector being readily inserted into them by competent workmen. In itself it provides a false joint, fulfilling all the mechanical conditions of the joint, while that is kept under the best influences for proper recovery.

It combines all the valuable or necessary movements of all the joint-splints in use, and is much more simple and easily managed.

THE BRITISH MEDICAL JOURNAL states that not a single case of the plague occurred among the Kal-mucks, who live totally regardless of sanitary rules, although the disease recently prevailed epidemically only a short distance from them. The conclusion seems to be that the disease is really due to some other agent than anti-hygienic conditions.

ULCERATION OF THE CERVIX UTERI COMPLICATING SALPINGITIS, AND ANTERIOR AND POSTERIOR VERSION.

By HORATIO R. BIGELOW, M.D.,

WASHINGTON, D. C.

For the expressive title of "Anterior and Posterior Version of the Uterus" I am indebted to Dr. Samuel C. Busey, who published a most interesting case under this heading in Vol. III. of the Gynecological Transactions. After reading his reprint, I am induced by his suggestion of its propriety to report a case of somewhat similar nature, but even more complicated in detail. It is the more phenomenal as occurring in an unmarried female.

History.—Miss A., 22 years of age, unmarried, the daughter of a distinguished lawyer and member of Congress, consulted me on June 5th, giving the following history: She had always been an ambitious student, a great reader, and of literary tastes. She was reared in all the luxury that wealth could give, and had indulged in those dissipations, so subversive of physical well-being, which the civilization of the age encourages. Two years previously she had over-exerted herself by getting up in the night and accompanying a young lady to witness the conflagration of the county court-house. Since that time she has complained of a fixed and constant pain in the occiput, spasmodic muscular contractions, dimness of vision, with conjunctival congestion; pains in the back and loins, in both iliac regions; rectal and vesical tenesmus, and general debility.

Appearance at time of consultation.—The patient is below the medium stature, of a bilious habit, pale and thin. Her face is flushed, with head thrown back; both eyes suffused; pupils dilated. The central retinal artery of both eyes is congested. There is a constant and fixed pain in the occiput, with occasional tonic and clonic contractions of the fingers, and considerable idriosis. She is unable to walk any distance, and can sit up but for a short time. Two weeks prior to her arrival in Washington she says that she had two spasms. She complains of pain in the back, of neuralgic pains following the course of the ascending and descending colon, of pain in both thighs, and of a frequent desire to urinate. She has suffered from a catarrhal discharge from the vagina, which has frequently been tinged with blood.

Pathological conditions.—The patient being in the dorsal position, a digital examination, which was effected not without difficulty, discovered a round, enlarged body occupying the cul-de-sac of Douglas, which proved to be the fundus. The cervix was tilted up upon the symphysis pubis. The vaginal walls were hot, swollen, and dry. The neck was rough to the touch, enlarged, and doughy. Placing the patient in Sims's position, I endeavored to tilt the womb over into a normal position with the dorsal aspect of the first and index fingers, asking her to take a deep inspiration, and at the moment of lifting to make a prolonged expiration. Failing to accomplish anything in this way, I introduced the sponge-holder, and by abdominal manipulation I succeeded in replacing the organ; but, immediately upon withdrawing the instrument, it assumed its condition of retroversion. I then introduced a Simpson's sound, hoping to use it as a lever. To my astonishment it passed up over five inches. After a little patience I found the normal measurement of three inches, and then passed the sound up the tube for at least an inch and one-half farther. I then told the patient that I

would not subject her to any continued annoyance, but would return upon the morrow, prepared to better her condition. I advised the free use of the vaginal douche of hot water night and morning, that she should abandon corsets, suspend her clothing from the shoulders, and rest in bed upon her side, with the head low and the hips elevated. My diagnosis was ulceration, retroversion, salpingitis. The next day I called with the intention of meeting these indications, but was utterly surprised to find the womb in a position of anteversion. I could not be mistaken in my diagnosis of the day previous, which was reached after great care, and hence concluded that it must be one of those rare cases of interchanging version. The patient being in Sims's position, through a Barnes' pledged speculum I carried a pledget of cotton, well saturated with a solution of subnitrate of bismuth and glycerine, to the cervix, and then carefully withdrew the instrument, so that the collapse of the vaginal walls might hold it *in situ*. I ordered her to remove it by means of the silk thread attached to it, at the end of twelve hours, and to insert a suppository of tannin and belladonna. On June 8th, after introducing a Sims's speculum, I found that the granulations were not as exuberant, that the color of the cervix was more natural, and that there was no bleeding. I painted the cervix with a saturated solution of tannin and collodion. I then took wads of prepared jeweler's cotton (saturated in a solution of bicarbonate of soda, and well dried), dipped them in carbolized oil, and carried one up into the fornix vaginae, pressing up the fundus, and the other opposite to it, over the cervix (the womb being anteverted). I then placed a tampon of the same material in the vagina, advising that she leave all in place for forty-eight hours. I prescribed a pill to be taken three times a day, as follows:

℞ Ferri redacti.....	gr. ij.
Quinæ sulphatis.....	gr. i.
Strychniæ sulph.....	gr. $\frac{1}{60}$
Arsenic.....	gr. $\frac{1}{30}$
Hyoseyamin (Merck).....	gr. $\frac{1}{65}$

and ordered the semi-abdominal decubitus for six hours a day. After two days I again visited her, and removed the tampon and rollers. The granulations were still flabby and unhealthy; these I touched with chromic acid, and painted the whole surface with the bismuth paste. After replacing the womb, I again resorted to the cotton supports, until I might devise some permanent apparatus which could be worn without danger of irritation. Hygienic and therapeutic treatment to be continued. I was much puzzled as to a means of holding the womb in proper position. Naturally, in primipare there is intolerance of any instrument that may occasion distention, and, in any event, the whole womb was so irritable that a peritoneal cellulitis might easily have been induced by a pessary of ordinary make. I determined to continue the use of the cotton until I could establish a *habit* of correct position in the uterus, even if it were of the very slightest degree; to use an ointment of tannin and vaseline over the hypogastrium, to relieve anæmia, and to act on the nervous system. Every forty-eight hours for two weeks I removed the cotton, washed out the vagina until I found that the uterus was accustoming itself to a slight condition of anteversion, when I introduced a pessary made for me after the following plan: A wire pessary of fine steel, with its opposite ends rounded off and parallel—somewhat after the manner of a Hodge's retroversion, if it were straightened out—was wrapped with carbo-

lized ligature silk, so that the end that should rest upon and support the fundus should be well padded, and of greater bulk than the other parts. Midway the pessary was divided by two padded wire septa, leaving a sufficiently large fenestrum for the cervix. The padded end I carried up under the fundus; then bent the pessary so that the cervix should be fixed in the fenestrum, the other part resting against the symphysis pubis. I dry-cupped the cervical region, and rubbed in croton oil behind the ears. The next day my patient complained of less pain, and said that she experienced no discomfort from the mechanical contrivance. I evacuated the blisters, and prescribed capsules of the compound pill of assafœtida and oil of anise. The pessary she wore for ten days; at the expiration of that time I removed it, and, finding the uterus in good position, but the vaginal walls flaccid, I prescribed suppositories, to be used night and morning, of tannin and belladonna, hoping to establish such contraction of the vaginal canal as that its walls might afford the necessary support. At the time of writing the patient is doing well; the uterus remains in position; the vaginal canal, having resumed its proper dimensions, serves as a support; there is no pain in the back, or rectal or vesical tenesmus. The pain in the occiput still continues, and it may be that I shall apply leeches to the temple and order Duquesnel's aconitine internally.

1502 FOURTEENTH STREET, N. W.

A CASE OF DOUBLE OVARIOTOMY.

By DR. JOHN I. DYER,

VISITING PHYSICIAN TO THE WASHINGTON ASYLUM, D. C.

A. M.—, German, aged thirty-five years, of sanguine temperament, mother of one child, now sixteen years old, was admitted into the Washington Asylum Hospital November 15, 1878, with a large tumor in the abdomen, supposed to be fibroid of the uterus.

Inquiry into the history of the case elicited the facts that the tumor was first noticed about the 1st of March, 1877, as a round ball in the left iliac region, and very movable. It grew rapidly, and was attended with almost constant pain. After seeking relief in various quarters, she was admitted, as above stated, into the hospital under my charge. The tumor was then as large as the gravid uterus at full term, very tense, elastic, and immovable.

Careful examinations made at different times, together with its rather rapid increase in size, led to the opinion that it might be a cystic growth of the ovary, and it was resolved to aspirate it. This was done on the 4th of February, and a gallon of fluid was drawn, with the result of diminishing its size about one-third.

Previous to, and after this operation, frequent attacks of pain in the abdomen, with tenderness on pressure and motion, were complained of, which were relieved by morph. sulph., and latterly suppositories of opium as needed.

With the additional light of a microscopical examination made by Dr. Schaeffer, and in consultation with Drs. Thompson, Eliot, and Ashford, the diagnosis of left multilocular ovarian tumor was made and ovariectomy advised, as giving the patient, already beginning to depreciate very markedly, her only chance of relief. She gave a ready and cheerful consent.

For three days before the operation she was restricted to a liquid diet exclusively, and on the morn-

ing of the operation her bowels were freely moved by enema. Twenty grs. quin. sulph. were given the night before, and tinct. foetid, $\frac{3}{4}$ ss., and tinct. opii gtt. l., in a small quantity of water, was thrown into the bowels a few hours before the operation.

Having thus prepared the patient, on February 26th I proceeded to operate, assisted by Drs. Wailes, Ashford, Eliot, and Reyburn. Being quickly brought under the influence of the anæsthetic, and the carbolyzed spray directed continuously upon the parts, an incision of about four inches, commencing just below the umbilicus, was made, and carefully dividing the abdominal parietes the tumor was exposed. A trocar was plunged into the presenting walls of a cyst, and its contents evacuated. A second and a third were thus opened, and the growth could only be partially drawn through the incision. This being enlarged downward an inch and a half, it was found that the tumor was firmly adherent, below and in front, to the uterus, whilst laterally and behind its whole circumference was attached by strong adhesions to adjacent parts.

These were with considerable difficulty torn through, and in doing so two cysts were ruptured and their contents lost, one of which contained from six to eight ounces of pus. These small arteries spirted and were secured by ligatures, which, cut short, were left in the cavity of the abdomen.

All adhesions being separated, it was found that the tumor was *right ovarian*, which by change of position in its early stage of development had fallen into the left iliac space. Its pedicle, consisting of the right broad ligament with Fallopian tube enclosed, being stretched across its lower anterior surface, spreading as it advanced toward the right side of the abdominal cavity into a broad expansion of very vascular peritoneal tissue.

Through about the centre of this, three ligatures were passed, and brought out through the abdominal incision. The left ovary was then sought for, drawn out, and found to be in a similar encysted condition, though much smaller in size—about that of a healthy kidney. Two ligatures were passed through its pedicle, brought out at the lower end of the wound, and the diseased ovary cut off.

Atlee's clamp was applied to the pedicle of the right ovary, and the wound—a glass drainage-tube being placed in its lower angle—closed with silver-wire sutures.

The time consumed in the operation was one hour and forty minutes, and this length of time must be taken as the measure of the difficulty met with in separating the close adhesions which bound the tumor to neighboring structures.

The weight of the solid portion of the tumors was six pounds. Their fluid contents were partially caught in a vessel conveniently placed; a portion, probably one-half, was unavoidably lost, and through the carelessness of one of the nurses, what had been collected was thrown away before its amount could be determined by weight or measure.

The patient, cold and nearly pulseless, was put to bed, hot blankets and bottles of hot water applied around her. Hypodermic injections of morph. sulph., $\frac{1}{4}$ gr. twice repeated, and of whiskey more frequently, were given, and in five or six hours she began to react, so that at 10 o'clock P.M. her pulse stood at 135, temperature 102° F. Towards morning the catheter was used. Nausea and vomiting distressed her during the night and for some days afterwards; but the plan of treatment, keeping her fully under the influence of opium, and using the antiseptic

tic treatment of the wound, was steadily kept up, with the result of a recovery, in what was considered at the end of the operation a hopeless case.

I will give a brief summary from notes taken at the time, of the progress of the case to the date of the separation of the ligatures, prepared by Dr. Timins, resident physician of the asylum, whose unceasing care and devotion to the case by day and night deserve the highest praise:

Feb. 27th, 6 P.M.—Pulse 135, temperature 99° F. Passed the first night with frequent attacks of retching, and complained of pain, referred to lumbar region. Crushed ice, opium in suppository, and morphia hypodermically used. Catheter used; but she had passed water, and continued to do so without difficulty thereafter.

Feb. 28th, 8 A.M.—Pulse 135, temperature 100.3° F. Great thirst and prostration. Small quantities of milk-punch and crushed ice given, but the stomach retained nothing. Severe pains, now and again in back, combated with opium suppositories and morphia hypodermically. Had short nap. 6 P.M.—Pulse 120, temperature 98° F.

March 1st, 6 A.M.—Pulse 114, temperature 99° F. Great epigastric pain. Ordered mustard poultice and hypodermic injection of morph. sulph., gr. $\frac{1}{2}$. Except cracked ice, nothing was given this day by the mouth. Nutritive enemata were given of milk, yolk of egg, and brandy to the second one, to which tinct. opii gtt. i. was added. Moreover, 4 grs. of opium in suppository was used during the twenty-four hours. Wound dressed; considerable overflow from drainage-tube, with but little odor. Cavity washed out with carbolized water.

March 2d.—Pulse and temperature as before. Gastric irritability worse. Small quantities of hot drinks tried. Also champagne and ice, bismuth, oxalate of cerium, bromide of potassium per rectum, with no benefit. Then nothing whatever was given by the mouth, merely moistened now and then with tea or milk. Nourishment restricted to enemata. This day tympanitis with borborygmus set in, annoying her more or less for the next four days. Assafœtida, turpentine, with other remedies, were given per rectum, which, together with the continued use of opium, kept the patient fairly comfortable.

March 3d.—Temperature 101.5° F. this day. Stomach tolerated a little beef-tea. Ordered quin. sulph., grs. xxx. per rectum.

March 4th.—Begins to take nourishment by the mouth, and, except on two occasions, vomited no more. Pulse fell to 100 this day and continued thereabout throughout the remainder of the time noted.

March 5th.—Ordered injection of warm water—carbolyzed—containing turpentine and assafœtida, with the result of a good movement from the bowels, and great relief of flatus.

March 6th.—Began to dress wound twice in twenty-four hours. Smaller-sized drainage-tube inserted.

March 7th.—Clamp and sutures removed.

March 8th.—Drainage-tube removed.

March 9th.—Considerable purulent matter and a large offensive flake washed out of the cavity this morning. Ligature of left pedicle still fast; no abdominal tenderness. Quin. sulph., gr. xx. per rectum.

March 12th.—Ligatures came away this day. Dressing reduced to once in twenty-four hours. The wound contracted nicely, and by the 24th inst. was entirely closed. The patient sits up, feeling well, and able to get about, which she will be allowed to do as soon as she gets an abdominal supporter.

Reports of Hospitals.

WOMAN'S HOSPITAL OF THE STATE OF NEW YORK.

SERVICE OF NATHAN BOZEMAN, M.D.

RETROFLEXION OF THE UTERUS, WITH FIXATION.

A CASE of retroflexion was shown in which the uterus was bent backward almost at a right angle, and yet in which the patient had not consulted medical advice until after the menopause.

The organ was in a state of marked fixation, which was thought to be probably the result of some former inflammatory process, although the only abnormal feature about the pelvis now discoverable, with the exception of the condition of the uterus, was the thickening of the broad ligaments, which is so frequently found in cases of this kind. The patient had been subject to uterine hemorrhage more or less severe and frequent, and the fundus had been in such a hyperemic condition, that the slightest touch of the probe was followed by quite a free flow of blood. This engorgement was being treated with applications of a solution of carbolic acid in glycerine, of the strength of half a drachm to the ounce, and also by the frequent use of hot vaginal douches. Under this course of treatment, decided improvement had taken place, notwithstanding the fact that it was as yet impossible to restore the uterus to its normal position. A little later it was proposed to accomplish this restoration by gradual pressure upon the vagina and the fundus uteri by means of the persistent use, for a sufficient length of time, of cotton columns applied in the vagina, in accordance with the method that has proved so successful in Dr. Bozeman's hands.

The plan is original with him, and is somewhat as follows: The patient having been placed in the knee-elbow position, and Bozeman's speculum introduced, a pledget of carbolyzed cotton is pushed up against the fundus with a pair of dressing-forceps, and held in position there by means of the perineal elevator ordinarily employed in connection with this speculum. A second and third pledget is then applied in the same manner, the perineal elevator being drawn a little further out as each is introduced; and this process is carried on until a firm column of cotton, not stuffing up the whole vagina, but of comparatively narrow diameter, has been formed that reaches obliquely from the fundus of the uterus to the symphysis pubis, which is here the *point d'appui*. Such a column may ordinarily be left in position for about two days, but should not be allowed to remain for longer than forty-eight hours. These columns should be put in about every three days, the patient being allowed to rest for twenty-four hours after the removal of each one, and vaginal douches being used in the interval. When by this means the uterus has been restored to its normal position and the vagina to its normal condition, any appropriate support may be worn by the patient as long as is necessary, and that which is best adapted for the purpose is the instrument known as

BOZEMAN'S VAGINAL SUPPORT.

It has been thus described by Dr. Bozeman, in a paper presented to the American Gynecological Society in 1878:*

* The Mechanism of Retroversion and Prolapsus of the Uterus considered in Relation to the Simple Lacerations of the Cervix Uteri and their Treatment by Bloody Operations. *Gynecological Transactions*, Volume III.

"This instrument is constructed upon the principle of the parallelogram. It is elastic and thoroughly self-sustaining. The instrument is made of coiled steel wire. It has vesical and rectal branches, which are covered with thin rubber up to points near the heel of the instrument, where an opening is left for the escape of the menstrual and other discharges. Upon the vesical branch is set a hair cushion which is to receive and support the vesico-vaginal septum. The covering of the rectal branch is distended with air, in order that it may adapt itself uniformly to the recto-vaginal septum. The two upper uneven points are united by a broad elastic apron, which, like a chair, is to receive the cervix uteri, and, to a certain extent, support the weight of the entire organ. When viewed edgewise, the instrument presents somewhat the appearance of a jockey's cap, and a medical friend suggested that it be called the 'jockey-cap pessary.' However, to avoid the name of a uterine pessary, I prefer to call it a *vaginal support*. This name is in strict accord with the action of the instrument, for it leaves the uterus and its relaxed ligaments to take care of themselves in their normal relation and position. This is an attainment of the highest aim I can conceive for any form of instrument employed for the latter purpose."

The great objection to its use is, that after a time it becomes offensive on account of the absorption of the vaginal discharges by the rubber with which it is covered; but this can be obviated, to a great extent, by providing the patient with two of these supports, so that she need not wear either instrument very long at a time. After one of them is removed it should be thoroughly cleansed with a solution of permanganate of potassa. It may be stated also that improvements are now being made in the construction of the instrument, which will prevent it from becoming thus offensive. One advantage connected with this instrument which has not been mentioned, is that the patient can be readily instructed how to introduce and adjust it, as well as to withdraw it, herself.

Where there is antelexion or anteversion instead of retroflexion present, the treatment is the same in principle. Here the patient is placed preferably on the back, while the column of carbolized cotton is built up from the perineum as the *point d'appui*, and extends obliquely to the vesico-vaginal septum, where the body or the fundus rests. When the organ has once been restored, the vaginal support is to be worn as before.

SMALL PELVIC TUMOR OF DOUBTFUL DIAGNOSIS.

In this case, there was a mass at the side of the uterus somewhat in the region of the left ovary, of several years' growth, which had pushed the body of the uterus to some extent over the right, and which occasioned the patient a great amount of severe pain. It was situated at a point just above the juncture of the cervix with the body of the uterus, and the exact nature of the tumor had not as yet been determined. The fact that it was close to the uterus, as well as its very slow growth, seemed to exclude the ovary as the seat of trouble, and the diagnosis lay, apparently, between cyst of the broad ligament and fibroma of the uterus. There were some points in favor of both of these hypotheses.

Thus there could be no doubt that it was intimately associated with the uterus, as its mobility, aside from that of this organ, could not be established; but still it certainly had not that firm consistency which ordinarily characterizes uterine fibroids. Yet, on the other hand, while the mass yielded, to

some extent, to pressure made upon it by the fingers, it was not nearly as soft to the touch as cysts of the broad ligament are apt to be, nor did it present that sense of fluctuation which, as a rule, is met with in these growths. The diagnosis was thus left somewhat in doubt; but it was proposed, a little later, unless some new developments should be made in the case, to puncture the tumor, and see whether it were not really a cyst. The pain, in Dr. Bozeman's opinion, was probably due simply to the increasing distention of the growth, and not to the pressure produced by it upon the surrounding pelvic organs, as its size was such that it would hardly be likely to occasion much inconvenience in this way. If this idea were correct, great good would no doubt be accomplished by the proposed puncture, on account of the relief from pain which it would thus afford.

BOZEMAN'S SPECULUM.

During the examination of this case, Dr. Bozeman at one time made use of Sims' speculum in connection with his own (which afforded a very perfect view of the os, cervix, and vagina); but this is never necessary when one has at hand the special perineal elevator, somewhat like a narrow spatula, which is ordinarily employed with his instrument. Bozeman's speculum is a bivalve instrument, which, by an admirable mechanical contrivance, is made to work on the principle of the parallelogram of forces, according to which, the greater the resistance, the greater is the power exerted. Hence, as the blades become more and more widely separated by turning the ratchet which controls their action, the force with which they distend the vaginal walls is gradually increased, while, in addition, their distal ends flare to a greater and greater extent. This renders the instrument self-retaining, and the services of a nurse or attendant can therefore be altogether dispensed with in its use. Other advantages of this speculum are, that the blades, being comparatively narrow, and, being widely separated when in position, the best possible view of the parts can be obtained at the same time that ample room is afforded for performing any operation about the cervix or vagina; and that it can be used while the patient is lying upon the side or back, or is in the knee-chest position, which, in many instances, is decidedly preferable. When the instrument is employed with the woman on her back, Dr. Bozeman is in the habit of slipping in a third or posterior blade (for which there is a provision made), and the perineal elevator above mentioned can also be used at the same time, if desired, which makes a complete and excellent four-bladed speculum of it. When the patient is in either of the other postures, only the perineal elevator is necessary.

LARGE FIBROMA OF THE UTERUS.

A patient, thirty-three years of age, had a large fibroma of the uterus, which had given rise to so much metrorrhagia that she had become exsanguinated to a very serious degree. It was in the posterior wall of the organ, and when the case was first examined, it was thought that it extended only the length of the normal uterus, to which distance only could the probe be passed.

So far from this being the case, however, it was soon ascertained that the fibroid reached fully to the height of the umbilicus, if not a little above this point. If the abdomen could have been more readily compressed, the fundus would no doubt have been felt very much in its natural position, with the exception of its being thrust slightly forward by the fibroid,

while between the two the fingers would have passed into a distinct sulcus.

When the speculum was introduced, the lowest portion of the growth could be plainly seen behind the cervix, and the os externum was found to be very widely dilated, with some eversion of its lips. Still, the mucous membrane of the cervical canal was quite healthy in appearance, as far as it could be seen.

When the patient first came under observation, it was believed that the fibroid projected to some extent into the uterine cavity, and that it would probably be a good case for the employment of Thomas's serrated scoop; but later investigation showed that this was not really the fact. Dr. Emmet had recently seen the case in consultation, and he had concurred in the opinion that no operative procedure should be attempted, for the present at least. The great point now was to build up the patient's general health in every way possible; and since her admission to the hospital she had improved very much in this respect, at the same time that the uterine hemorrhages had become much less frequent and copious than they had been previously. The only local treatment that she was receiving was the hot-water vaginal douche, and the painting of the cervix, and Douglas's cul-de-sac, two or three times a week, with Churchill's tincture of iodine. In case the metrorrhagia should return more freely, it was recommended that the iodine should be applied within the cavity of the uterus also. Internally she was taking two drachms of Squibb's fluid extract of ergot three times a day, in the hope that the contractions caused by it might have the effect of forcing it, to a greater or less extent, down into the cavity of the uterus.

PROLAPSED AND IMPRISONED OVARY IN A CASE CURED OF VAGINITIS AND VAGINISMUS.

This patient had recently suffered very greatly from vaginismus, which was due to vaginitis formerly existing, and this had been successfully treated by the method of systematic and continued dilatation. There still remained, however, an abnormal condition of the ovary, which gave her a great deal of distress, and which was the cause of various shooting pains about the hip, pelvis, and down the thigh, that are, as a rule, characteristic of this difficulty.

The right ovary, probably on account of its being in a state of marked congestion, had become prolapsed, and had slipped down, not into Douglas's cul-de-sac, as sometimes occurs, but simply behind the broad ligament, and had there become imprisoned, as it were.

The local treatment consisted in pressing the ovary up as far as possible into its normal position by means of a cotton tampon; and it was stated that, even in cases where the organ remained fixed in its prolapsed situation, great relief from suffering was not infrequently experienced by the patient, merely on account of the pressure exerted upon the organ. The patient's general condition had improved very greatly during her residence in the hospital.

VESICO-UTERO-VAGINAL FISTULA, COMPLICATED WITH INCARCERATION OF THE CERVIX UTERI IN THE BLADDER.

When first admitted, this case had been a very complicated one. The fistula was immediately in connection with the cervix, and that portion of the uterus was actually protruding into the bladder, while the body of the organ itself was in a state of complete retroflexion. This displacement had now been rectified, and several preliminary operations, in pursuance

of the method of lateral incisions, had already been performed. Nitrate of silver was being applied locally from time to time, and it was hoped that before long the final operation for the complete closure of the fistula, might be undertaken with a reasonable hope of success.

CYSTOCELE AND HYPERTROPHY OF THE URETHRA.

The last case seen was one in which Dr. Bozeman had performed ovariectomy six or eight weeks previously. The operation had been a complete success in every way, but, in addition to the ovarian trouble, she had suffered from a considerable degree of prolapsus of the uterus, together with marked prolapse of the anterior wall of the vagina and the bladder, and hypertrophy of the urethra. Since the ovariectomy, the prolapsus of the uterus had been gotten rid of, but there still remained the other difficulties named. Attention was now being directed mainly to the condition of the urethra, and twice a week a solution of forty grains of nitrate of silver to the ounce was being applied to the urethral canal, while a solution of sixty grains to the ounce was applied about its orifice and the adjacent mucous membrane.

After the urethra had been restored as far as possible to its normal condition, it was proposed that the patient should wear one of Dr. Bozeman's elastic vaginal supporters, and it was believed that if she did so constantly, the presence of the cystocele still remaining would not occasion her any inconvenience whatever. The great advantage of this supporter, as above stated, is, that it can be adjusted at will by the patient herself; and it is found to be of service in a very extended variety of cases. Especially is it valuable in instances of hypertrophy and congestion of the uterus, where the patient is subject to marked menorrhagia and other troublesome symptoms. Almost invariably, in such cases, after the woman has worn the supporter for some little time, it is found that the menorrhagia disappears entirely (the catamenia lasting only the normal period, instead of a week, or even ten or twelve days), and, the congestion of the uterus being thus relieved, that all sense of weight and discomfort about the pelvis is dissipated.

Progress of Medical Science.

TYPHOID FEVER DUE TO THE INGESTION OF DISEASED MEAT.—An epidemic of typhoid fever, interesting in its etiology, followed a musical festival at Zurich, in May, 1878. Out of some 700 assistants, 500 were attacked by the disease, of whom 100 died. The symptoms could not be mistaken, and the autopsies confirmed the diagnosis. A minute inquiry into the circumstances left but little doubt, that the epidemic was due to the use of bad veal furnished by an inn-keeper of the place. It may be claimed by those who attribute to general causes the power of originating specific diseases, that the typhoid fever was due to a septic poison present in the veal, depending possibly on a beginning fermentation, which was not destroyed by the cooking to which it had been submitted. On the other hand, as the animal from which the meat was taken was sick, it may be asked whether it might not have been suffering from typhoid fever, although this disease has never yet been recognized among animals. It is a remarkable fact that in 1839 a similar but much less fatal epidemic occurred in a neighboring locality. After a reunion that took place under similar circumstances, 440 persons were taken sick with all

the symptoms of typhoid fever. It is probable that in this case also the meat of a sick calf gave rise to the disease.—*Journal de Médecine*, June, 1879.

AN OINTMENT FOR CHRONIC PAINS.—The following is recommended for the pains of chronic or sub-acute gout, rheumatism, neuralgia, etc., by Dr. Leno-ble, of Esternay:

R. Pulv. Gambogiæ,
Myrrhæ,
Canellæ,
Sodæ salicylat. ʒ 10 grammes,

reduced to the proper consistency with spirits of turpentine. The affected part should be well rubbed with this three times a day, and then enveloped in cotton or wool.—*Revue Médicale*, June 14, 1879.

OCULAR CHANCRE.—The following case is reported by M. Boucheron: A young woman, eighteen years of age, presented an intense redness of the conjunctiva, the pericorneal injection of iritis, the hypertrophy of the semi-lunar fold seen in certain cases of palpebral granulations, and the symptoms of a foreign body present in the internal angle of the eye. A careful examination revealed a small ulcerated groove, with gray borders, on the semi-lunar fold. A chain of indurated glands was also found, extending from the pre-auricular gland, behind the angle of the jaw, to the lateral region of the neck. A diagnosis of indurated chancre was made, and confirmed shortly afterward by the appearance of a confluent roseolar eruption. Cases analogous to this have already been observed; among others, that of a professor of the *Faculté de Paris*, lately dead, who was also inoculated on the semi-lunar fold, the poison being conveyed thither on his finger, while endeavoring to relieve an itching of his eye, immediately after examining a woman. In M. Boucheron's case, the poison was probably communicated by means of a kiss from a person suffering from mucous patches of the buccal mucous membrane.—*Gazette des Hôpitaux*, June 14, 1879.

ORGANIC STRUCTURE OF THE PROSTATIC URETHRA.—The existence of stricture of the prostatic urethra, although maintained by Leroy d'Etiolles, Ricord, Civiale, and others, is denied by Sir Henry Thompson, who has been unable to find any anatomical specimen proving it, and who rejects as unreliable evidences drawn from examinations of the living body. The following case, however, reported by Dr. Mastin, of Mobile, Ala., deserves examination:

J. B., aged 46, applied in June, 1877, for relief of stricture. He had contracted gonorrhœa in 1856, and again in 1861; shortly after which his stream of urine diminished in size. In 1871 and in 1874 he was attacked by complete retention, which was only relieved by forcible catheterization. At this time (June, 1877) he could only pass his water by drops. On examination, a sound, No. 22 F., could be passed down the urethra with ease for a distance of seven and one-quarter inches, beyond which not even the smallest filiform could be introduced. This, according to Sir Henry's measurements, would place the obstruction at the apex of the prostate. Otis's urethrometer showed the normal calibre of the urethra to be 32 mm., and the canal anterior to the prostate to be free from contraction, except at one point about an inch anterior to the bulb, where it was narrowed to 21½ mm. External perineal urethrotomy was determined upon, and Dr. Mastin proceeded to cut down upon the end of a staff. Opening into the membranous urethra, he placed his finger upon the

apex of the prostate, and proceeded to satisfy himself that there could be no mistake as to the position of the stricture. It was unmistakably within the prostate. After some difficulty a Maisonneuve urethrotome was carried into the bladder, and the stricture divided. The patient did well. Nine days later, the anterior constriction was operated upon, and a sound, No. 32 F., carried into the bladder. Eighteen days after the first operation, he was discharged cured. To guard against the mistake, pointed out by Sir Henry Thompson, of regarding the narrowing of the canal occasioned by certain enlargements of the prostate as organic stricture, a careful examination was made at the time of the operation. There was no hypertrophy of the gland; on the contrary, it was below the average size. Dr. Mastin is inclined to think that the trouble started first in a prostatitis, and was afterward aggravated by the mechanical injury suffered from the forcible introduction of the catheter.—*The Boston Medical and Surgical Journal*, July 26, 1879.

METHOD OF REMOVING HAIRS.—A writer in the *Michigan Medical News* gives the following method of eradicating superfluous hairs, as practised by Dr. C. E. Mitchell, of St. Louis: The hair is seized and held with a pair of ordinary forceps, and a sharp needle fastened to a handle (a small, sharp pegging-awl will do) is passed down parallel to the hair, within its sheath, until the bottom of the follicle is reached; the point of a small needle, also provided with a handle, is then dipped into some fused nitrate of silver, until a minute ball of crystals gathers around the point, and the hair-follicle is thoroughly cauterized with this miniature caustic point thrust through the puncture previously made. In a few hours the hair will ulcerate out by the root, without pain; no visible lesion is left, and the hair does not grow again.—*The Medical and Surgical Reporter*, June 28, 1879.

PUSTULAR INFLAMMATION OF THE VAGINA.—The following case is reported by Dr. Herman, of the London Hospital: A woman, aged 27, applied for relief from a thick yellow discharge from the vagina. A tolerably distinct syphilitic history was obtained. On digital examination, the vagina was felt to be studded with small, hard, raised, roundish, shot-like swellings, varying in size from a small shot to that of a small pea. These were most numerous at the upper part of the vagina, where they were so abundant as to become confluent in spots. With the speculum these were seen to present different appearances. Some were simply papule-like elevations; some were smooth, rounded, but yellow in the centre, as if containing pus; some presented on their summits crater-like depressions, lined or bordered with yellowish white—seemingly pustules which had burst; and some were simply small, superficial ulcers. Between these diseased parts, the nearly healthy mucous membrane could be seen—smooth, but somewhat bluish in color, and more injected than the healthy membrane nearer the vulva. The vaginal portion of the cervix uteri presented appearances somewhat similar to those of the general vaginal surface: it was red and raw-looking everywhere, and when first seen pustules were present. The vagina and os uteri contained a thick, yellow, glutinous discharge. Dr. Herman has himself seen no other case of the kind, nor has he been able to find records of any similar case. In the "granular vaginitis" described by Deville, pustules are not mentioned as being present.—*The Obstetrical Journal of Great Britain and Ireland*, July, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

Wm. Wood & Co., No. 27 Great Jones St., N. Y.

New York, August 30, 1879.

THE REGULATION OF PROSTITUTION AS A SANITARY MEASURE.

THERE is no doubt of the fact that the majority of the medical profession are in favor of some method of so regulating prostitution as to diminish the amount of disease that its existence entails. Being, as they are, brought constantly in contact with the immense evils which venereal diseases inflict upon society, it is natural and praiseworthy that they take the ground they do. We believe, however, that there is a very general ignorance of the exact results of the regulation systems now in vogue, and we propose to present some facts upon this point.

The position of the sanitarian and regulationist is essentially this: Venereal disease causes direct injury to the citizens of the state; it cripples their activity, and may throw them as a burden on the government. The government, therefore, has a right to protect itself from such disease as much as from small-pox or typhus. In order to do this there must be a governmental supervision and medical examination of prostitutes. In defence of the justice of such plan, it is claimed that the prostitute is to be regarded as a person who has certain things to sell; she follows a trade, and she has no right to sell goods which damage and infect society. There should be protection given here, just as well as from poisonous adulterations in any other branch of trade.

From another standpoint, again, it is argued that prostitution is inevitable, and its existence is necessary as a safeguard against worse evils. Therefore, what is inevitable and necessary should be rendered as innocuous as possible. It is asserted, further, that duties and rights are correlative. If a person fails to perform the former, he or she cannot claim the latter; and prostitutes, not having performed their duties, have thus abrogated their rights. Stripped of casuistry and elaborate statement, the point of the matter

is, that a great danger is to be guarded against, and the end justifies the means.

Whatever train of argument may be followed, we believe it a legitimate conclusion that, if any law or regulation can lessen the dangers from venereal diseases without greatly violating justice or natural rights, it should be adopted.

We do not propose, and it is not our province, to discuss the moral side of the question, any further than it involves this question of natural rights, but simply to discover whether, as a sanitary measure, some system of regulation may not be adopted which will be just, efficient, and worthy of encouragement. There is a great deal of material before us now for judging whether this is possible. For many years the regulation system has been working in various countries in Europe. In one country—England—it has been partially adopted by law; elsewhere it is a municipal regulation only. For three years it was tried in St. Louis, and an effort—summarily crushed, however—has been recently made to revive it there. It is at present the subject of parliamentary inquiry in England.

From a review of the evidence so far collected it is impossible to avoid the conclusion that in most places the system is a decided failure, while in England only, under peculiar conditions, it is, to a certain extent, a success. This failure lies in the fact especially that, as a sanitary measure, the "regulations" are miserably inefficient. There is an abundance of statistics pointing to this conclusion.

In Paris all prostitutes are compelled to register themselves as such, and subject themselves to periodical examinations. There is so strong an effort to evade this regulation, that out of the 30,000 prostitutes in that city only about 4,000 are registered. The remainder, as well as all the men who consort with them, thus escape inspection and may disseminate disease. As inspections are made only twice a month, it is evident that there is no great security even among those who are examined. This is shown by the fact that among those examined during the decade ending in 1875, the amount of gonorrhoea and non-specific diseases of the genital organs increased from 43 to 195 per thousand. The number of syphilitic cases increased from 892 to 1,044. The number of venereal cases treated in the hospitals was, in 1867, 6,359; in 1875, 6,568. It is asserted by Dr. Drysdale that the number of venereal cases in the London hospitals is less than in those of Paris. This increase in disease has taken place in spite of particularly stringent efforts to carry out the regulations completely. On the whole, the reports of the Bureau des Mœurs, which has this system in charge, show that only about one-eighth of the prostitutes are reached, that the gonorrhoeal diseases are greatly increased and syphilis slightly so, all this in spite of an elaborate and very expensive system of attempted repression. Remem-

bering the infrequency of inspections, it is not difficult to understand this. An inspection twice, or at least once a week, is necessary to secure any tolerable degree of safety. We are unable, therefore, to draw any other conclusion from these facts than the one that has been expressed, and M. Le Cours himself, the Chief of the Bureau des Mœurs, asserts the same opinion. "This state of things," he says, "reveals the existence of a social malady which no mere police measures are able to cope with or destroy. . . . It is impossible by any such measures to make cohabitation with a harlot safe."

It seems to be generally acknowledged that if laws cannot be carried out in Paris they will be sure to fail elsewhere, and an examination of the workings of the regulation system in other cities proves this to be true. The same facts of limited registration and unlimited venereal disease appear among them. Better results, to be sure, are claimed for the British Contagious Diseases Acts, and we are inclined to believe the claim valid. These acts are intended for the protection in particular of the soldiers and sailors, and they apply only to certain garrisoned towns. Concerning them their opponents say that they are unconstitutional; that they do a gross injustice to the woman, and that under them there has been an absolute increase of gonorrhœa, as well as to a less extent of syphilis. This asserted increase of syphilis is not clearly shown, though the decrease, if any, has been small. The increase of gonorrhœa, however, was up to 1878 a fact; during this last year, however, that disease also was, according to the reports, markedly decreased in the army, though not in the navy.

To offset this lack of striking sanitary results, however, it appears that the prostitutes themselves live more comfortable and orderly lives, and greater outward decency is obtained. But even assuming these acts to be just and efficient, it furnishes no argument for a general extension of similar regulations to ordinary cities. The social conditions in these and in small garrisoned towns with 20,000 celibates quartered upon them are immensely different.

In this connection the *Medical and Surgical Reporter*, referring recently to the apparent success and general endorsement of the British Contagious Diseases Acts, lamented the backwardness and timidity of American medical journals in not advocating the adoption of regulation acts with us. We can only say that our esteemed contemporary appears to have been led by an ignorance of the nature and extent of those acts to an unjust criticism of their brethren. Medical journals will advocate regulation when the experience of those who have tried it will justify them in doing so. But at present it does not.

We assert again, therefore, that the regulation system as now applied to ordinary communities fails to prevent the extension of venereal diseases. It is, indeed, absurd to suppose that semi-monthly exami-

nations of one-eighth, or more properly one-sixteenth, of those liable to communicate infection can attain any adequate results.

This fact of sanitary failure is so thoroughly established, that one of two grounds only can be taken in regard to the matter. We must either give up the idea of regulation entirely, or we must seek some new and more efficient method than that now in practice. We have so far failed to learn of any practicable substitute for the present methods. The matter was referred to a committee at the annual meeting of the American Medical Association in 1874, and their appreciation of the difficulty may perhaps be inferred from the fact that they have not yet reported upon it.

We have a word to say, in conclusion, concerning the ethics of the matter. We cannot accept the position that the prostitute has forfeited her natural and legal rights, and that she is not entitled to justice in the laws made concerning her. She sells, to be sure, and that is admitted to be base, while the man buys, and that is considered only foolish; but the offence is the same in both, and the law should not make one only the criminal. Woman's sphere of labor is narrow, her wages pitifully small, and she is paid best for prostituting herself. She is often forced into the trade by very necessity. It is hardly just therefore that the laws should protect man alone.

This fact has often been recognized, and attempts been made to carry out a double inspection. But so far they have been found impracticable.

Out of the fertility of the human mind there may in time come some efficient system of regulating prostitution; at present, however, its future looks as dubious as its past has been unsuccessful.

HAY-FEVER.

At the present time there are probably nearly 50,000 people suffering from what is called hay-fever.

When this affection was first recognized it was supposed that it depended upon the irritation produced by the pollen of certain flowers and grasses which floated in the air in the months of May, June, July, and August of each year.

Subsequently it was claimed that two distinct forms of the disease existed, and to one was given the name of "June cold," while the other received the name "autumnal catarrh."

Further observation revealed the fact that an affection characterized by symptoms essentially the same as those seen in connection with hay-asthma, hay-fever, June cold, rose cold, autumnal catarrh, etc., occurred in seasons of the year in which none of the supposed exciting causes of the hay-fever could operate, and for some time the reasoning was that it must be some other disease than that produced by the pollen of plants. It was also observed that certain persons were peculiarly affected when brought in contact with certain animals, such as the cat, and by the

vapor from certain animal substances, such as warm milk. These observations, and others of like character, have from time to time led to modifications of former opinions regarding the nature of hay-fever, and, at last, have given rise to a theory which has been promulgated as one capable of explaining all the phenomena of the disease whenever and wherever occurring.

In this country two books have been written on hay-fever: one—the oldest, and for a long time the only systematic monograph upon the subject—by Dr. Jeffries Wyman, of Boston; the other by Dr. Geo. M. Beard, of New York. In Dr. Beard's book we find the first open announcement of the theory to which we have already referred, namely, the "nerve theory." This theory is the result of the study of one hundred cases, and it is that hay-fever is a neurosis. According to this theory, the disease is subjective instead of objective; external irritants, which are exceedingly numerous, such as rag-weed, pollen, etc., are of a secondary and a tertiary character and powerless in themselves to produce the disease, and produce the disease only when acting on a nervous idiosyncrasy. This author has described a new form of the disease, which he calls the July cold, or middle form, which links the early form, or June cold, with the later form, or autumnal catarrh. It seems to us that the nerve theory explains many of the cases which have heretofore been regarded as very obscure; for example, those in which the symptoms peculiar to hay-fever have continued from May to November, or during the winter months, or all the year round. If the nerve theory be true—and it seems to be fairly sustained—it revolutionizes the treatment of the disease. It must be attacked from a new point of view; yet it cannot be successfully claimed that all cases are to be treated alike, or that any specific can be found for it. The remedies to be employed are those which are not painful—not even disagreeable. Of course, removal from the exciting cause is the primary factor in obtaining prompt relief; but, when this cannot be effected, the symptoms can be greatly relieved, and many cases cured, by such remedies as arsenic, nux vomica, carbolic acid, belladonna, tonics and sedatives, electricity, etc., and their combinations.

IMPROPER USE OF PHYSICIANS' PRESCRIPTIONS.

The pilfering tendencies of some druggists is an acknowledged fact. Not long since it was made known to us that a druggist claimed that a single prescription made by an eminent surgeon, had, within ten years, been worth to him ten thousand dollars.

If, in any instance, those who pilfer would use all the prescription, no more and no less, it might be an element of safety in the absorbing process; but when the druggist puts on the livery of the "knowing" instrument-maker and insists that he can make valuable improvements upon the original design, then it

is that his asinine qualifications loom into view, and the consumer of his nostrum unknowingly runs the risk of being killed or permanently injured.

Not long since a druggist in one of our western cities maltreated a physician's prescription to such an extent that, instead of sending capsules containing sulphate of quinine and Dover's powder, he sent capsules containing cincho-quinine, capsicum, and rhubarb. In this particular case the patient called the physician's attention to the fact that the medicine last obtained at the drug-store seemed to be different from that which had first been taken, and the statement led to the discovery that the deformed prescription had been written by the druggist, and yet it was properly signed by the physician's name. Imagine the physician's surprise; and, being a calm man, he said that if such practice was indulged in to any extent by druggists it would lead to serious trouble. We should hope it would; at least for the druggist.

The attention of our readers has, on former occasions, been called to the reprehensible practice which some druggists have of abridging the prescription of the physician as well as substituting one drug for another that has a similar physical appearance. All these breaches of good faith between the druggist and the doctor should be treated in the most prompt and radical manner known both to the law and to the code of medical common sense.

Reviews and Notices of Books.

QUESTIONS ON FOOD AND CLOTHING, FOR HOME LESSONS AND EXAMINATION. By MRS. W. T. GREENUP.

HERE is a little primer containing 190 questions, divided into nineteen lectures and followed by a supplement containing four additional questions, and a chapter on clothing containing 114 questions, with a supplement containing six questions.

If all the girls in the United States were compelled to study and to labor until they could give a good, clear, practical answer to all these questions—answers based upon a personal ability to demonstrate their truthfulness—what a contribution it would be to the aggregate domestic felicity of our country! For example, the following question meets us, and, in turn, is followed by a wonder as to how many can answer it and then carry the answer into practical effect:

"If mother were from home, and you had to keep house for a week, how would you manage to have a hot dinner every day for father, self, and brother, supposing you had but one joint of meat in the week? Say what you would have on each day of the week." We fear it is more than probable that, in a very large proportion of cases, the answer *now* would be, "Go to the restaurant;" for, according to Bayard Taylor, the word is derived from *res*, a thing, and *taurus*, a bull. Hence, it is a bully thing, and especially so under the circumstances of mother being absent from home. Fortunate, indeed, are the fond fathers whose daughters have dotting mothers who can give a practical solution to this apparently formidable question. Yet there are very many who can answer the question

practically, and thus swell the heart of paterfamilias with delight and his stomach with good food.

Food and *clothing* are two corner-stones in the monument to be erected to preventive medicine, and were every mother and daughter throughout the land thoroughly familiar with their healthful preparation, it would be like the long arm of a powerful lever, with which the medical profession could operate in resisting the invasion and spread of disease.

OUR DOMESTIC POISONS; or, the Poisonous Effects of Certain Dyes and Colors used in Domestic Fabrics. By HENRY CARR, M. Inst. C. E. London: William Ridgway, 169 Piccadilly, W. 1879.

THIS writer, in his little monograph of fifty pages, gives his observations regarding the insidious character of *arsenical* poisoning, and states, contrary to a popular opinion, that arsenic is not confined to green color, but enters into the composition of a large number of dyes which are used for coloring wall-paper and dress fabrics. According to this author, arsenic enters into the composition of the aniline colors, and is also used in indigo dyes, where a mineral poison would be least expected. This is an important statement, and if knowledge of the fact could become general, it would probably lead to the removal of this element of danger from a class of dyes which of themselves act as irritants, to say the least, when they come in contact with the skin of some persons.

Cases of chronic arsenical poisoning are cited, and to the pamphlet proper are added letters from medical men and professors of chemistry.

It is a valuable article, because it illustrates the great value of preventive medicine.

COMPLIMENTARY DINNER given to Professor S. D. Gross by his Medical Friends, in Commemoration of his Fifty-first Year in the Profession, April 10, 1879. Philadelphia: Lindsay & Blakiston. 1879.

THIS beautiful monograph contains the preliminary arrangements, the speeches made at the dinner, the letters and telegrams received from gentlemen who were invited, but were not able to be present, the names of the invited guests, and the names of the subscribers. It also contains a most faithful likeness of the eminent professor in whose honor the complimentary dinner was given.

THE BRAIN AND ITS DISEASES. Part I. Syphilis of the Brain and Spinal Cord. By THOMAS STRETCH DOWSE, M.D. New York: G. P. Putnam's Sons. Pp. 144. Illustrated with colored lithographs and photographs. 1879.

THIS is a reprint of an English work which was reviewed in *THE RECORD*, June 21, 1879. It is elegantly printed and illustrated.

A TEXT-BOOK OF PHYSIOLOGY. By J. FULTON, M.D., M.R.C.S., Prof. of Physiology in Trinity Medical College, Toronto, etc. Second Edition, revised and enlarged. Philadelphia: Lindsay & Blakiston. Toronto: Willing & Williamson. Pp. 416. 1879.

THIS is a well-printed octavo containing 151 illustrations, some of which are duplicates, and almost all of which are old acquaintances. As its title indicates, it is written for the use of students, but only for students preparing for a pass-examination. It has the flavor, not of the laboratory, but of the library. The author has drawn diligently from many sources, and, as a rule, states conclusions categorically and without argument. Considering the size of the book, a noteworthy feature is the prominence given to histology.

PHOTOGRAPHIC ILLUSTRATIONS OF SKIN DISEASES. By GEORGE HENRY FOX, A.M., M.D., Clinical Professor of Dermatology, Starling Medical College, Columbus, Ohio; Member of American Dermatological Association, etc. Parts I. and II. Colored plates taken from life. New York: E. B. Treat, No. 805 Broadway.

IN these parts, which are the first of a series of twelve, we have illustrated comedo, acne vulgaris, lepra tuberosa, elephantiasis, keloid, rosacea, psoriasis nummulata, and ichthyosis simplex. With photographic accuracy these affections of the skin are given, although the reproduction is not made by the photographic process, but by a process from photographic negatives that gives equally accurate results. The skilled artist to whom has been entrusted the work of slight coloring, has done his work very well, and yet it almost seems as though he was a trifle timid on approaching some of the specimens, and hence somewhat hurried with his brush. It is so easy, by means of coloring material, to give false colors, that this part of the work needs to be done with very great care. None but a skilled artist should be entrusted with it; and none but a skilled artist who exercises the greatest care will succeed in giving satisfactory illustrations. The descriptions of the diseases which are illustrated are excellent, and the treatment such as will be of service to the general practitioner. We shall look for the subsequent parts with pleasure, and if the same degree of perfection is exhibited as in those which are before us, both author and artist will have won the compliments of the profession.

Reports of Societies.

BRITISH MEDICAL ASSOCIATION. FORTY-SEVENTH ANNUAL MEETING.

Held in the City of Cork, Ireland, August 5th, 6th, 7th, and 8th, 1879.

(Special Report for *THE MEDICAL RECORD*.)

(Continued from page 187.)

THURSDAY, AUGUST 7TH—THIRD DAY.

THE Association was called to order at 10 A.M. by the President, DR. D. C. O'CONNOR.

REPORT OF MEDICAL REFORM COMMITTEE.

DR. WATERS, Chairman of the Medical Reform Committee, read the annual report, in which, after giving a review of the work of the committee, special reference was made to the effort that had been made to secure a direct representation in Parliament.

On motion by DR. FALCONER, the thanks of the Association were extended to Mr. Arthur Mills, M.P., for his efforts in behalf of the medical profession, and for his able advocacy of the principles of medical reform.

REPORT OF THE COMMITTEE FOR PROMOTING LEGISLATIVE RESTRICTIONS FOR HABITUAL DRUNKARDS.

DR. ALFRED CARPENTER, President of the Council, read the report of the committee, in which the Association was congratulated on the passage of the measure introduced into Parliament, which could be considered the first installment of a more perfect measure. Dr. Carpenter, in moving the adoption of the report, said that in the course of a few months they would be able to provide typical institutions for

ladies and for gentlemen, rich and poor, so that cases could be treated and restored, and so that persons addicted to this vice might become useful members of society.

The report was unanimously adopted.

SCIENTIFIC GRANTS COMMITTEE.

The report of the Scientific Grants Committee showed that £120 had been appropriated for researches with the view of testing the application of antiseptic surgery in cases of lesion of the skull, brain, and its membranes; on the function of the kidney, and on the physical conditions which regulate the flow of urine; an investigation into the anatomical characters of certain diseases of the skin allied to tubercular, scrofulous, lupoid, and syphilitic affections; and investigations on anæsthetics.

ADDRESS IN SURGERY.

MR. WILLIAM S. SAVORY, F.R.S., lecturer and surgeon in St. Bartholomew's Hospital, then delivered his address on

THE PREVENTION OF BLOOD-POISONING IN THE PRACTICE OF SURGERY.

He said that blood-poisoning was undoubtedly the chief evil which waited upon the surgeon's work. It hovered over every operation; it was not yet a thing of the past, but much had of late been done to avert its evil effects. No one could tell how many lives were in former times sacrificed by blood-poisoning in its comprehensive sense, for, the nature of the mischief being unknown, it was in those times set down to various causes. He used the word "blood-poisoning" in its comprehensive sense to express the sum of the efforts produced by the introduction into the blood of matter charged by the action of septic poison. By septic poison he meant matter capable of producing or promoting putrefaction. There was a confusion in the current use of the phrase antiseptic surgery. That should mean the principle which arrived at the securing of healthy wounds, and those then repaired as speedily as possible by the most scrupulous cleanliness, not only in the common, but in the surgical sense. Thus understood, antiseptic surgery ought to be simply equivalent to good surgery. But antiseptic surgery, as commonly understood, implied the liberal employment in practice of special agents known as antiseptics, and in that sense again all surgeons now practised it. Finally, the term was now most commonly used to explain what was more precisely known as Lister's method of dressing wounds. Dr. Savory read a table which he had prepared, showing the statistics of blood-poisoning after operations in St. Bartholomew's Hospital for three years. From that it appeared that after 1,235 operations, the number of deaths from blood-poisoning was eighteen. The best results had been obtained by the simplest means. They aimed at the most scrupulous cleanliness. They watched very carefully the actual state of the wounds, and they used antiseptics of various kinds very freely. With cleanliness they attached the highest importance to rest. They disturbed wounds as little as possible during the process of repair; they were most jealous of the state of the atmosphere of the wards; ventilation was only effected by open windows and large chimneys. They avoided carefully any tendency to overcrowding of cases of wounds in the same ward, and each patient had from 1,100 to 1,400 cubic feet of space. They attached the greatest importance to the state of the health and the general condition of the patient before operation; and they never, when

they had choice and opportunity, performed an operation without previous inquiry in that direction. Dr. Savory condemned the use of drainage-tubes in wounds unless in exceptional cases. It should always be remembered that they were foreign bodies in a wound. They irritated and provoked suppuration and formation of fluids. That wounds did at length close in spite of this treatment he was well aware; but they would all heal more quickly and kindly without disturbance if they were simply closed in a way which he explained. He spoke highly of the value of common bread poultices, carefully made and renewed at proper intervals of time. With regard to Lister's plan, which arrived at excluding blood-poisoning by the rigid exclusion of living germs, judging the plan by facts actually ascertained, there were, he said, no trustworthy statistics to show that the results obtained under Lister's method was much in advance of those obtained by other methods.

At the conclusion of the address, Dr. W. K. TANNER offered the following resolution:

"Resolved, That the best thanks of this Association are due, and are hereby tendered to Dr. W. S. Savory, F.R.S., for his able and interesting address in surgery."

MR. REGINALD HARRISON seconded the resolution, and said that he thought the association was much indebted to Dr. Savory for his outspoken criticism upon subjects of such vital importance. He had not shortened the subject he had undertaken to put before them; he had fearlessly and ably criticised a matter which was now occupying, and had occupied for some years past, the attention of the surgical and medical professions. He did not care to venture on any further observations, but would like to remark, that, as an old pupil of Dr. Savory's, he felt very considerable pleasure in seconding the resolution which had been proposed by Dr. Tanner.

The resolution was then put from the chair and carried with acclamation.

"SURGEON-MAJOR REYNOLDS.

DR. CARPENTER, President of the Council, then presented Surgeon-Major Reynolds with the gold medal of the British Medical Association, for distinguished merit in performing professional service in Zululand, South Africa, Jan. 22 and 23, 1879, and caring for the wounded under fire. Surgeon-General Crawford responded in behalf of Surgeon-Major Reynolds, after which the Association adjourned, to meet on Friday at 10 A.M.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 25, 1879.

DR. E. L. KEYES, PRESIDENT, IN THE CHAIR.

(Concluded from page 188.)

CARCINOMATOUS STRICTURE OF THE ŒSOPHAGUS.

DR. ROBERT NEWMAN presented a specimen removed from the body of a gentleman who died in consequence of carcinoma of the œsophagus. The œsophagus was adherent to the spinal column. On opening the stomach there was evidently extension of the disease to the pylorus. All the other organs were apparently healthy. The interest in the case was the almost entire absence of symptoms. He had no pain at any time; there was no blood in the regurgitations, except occasionally at the latter part of a severe one, when slight streaks of blood were seen. The

entire duration of the case was about eight months, and the following is the history:

Mr. A. M., *æt.* 72 years, came under observation with dyspeptic symptoms on February 7, 1879, with the following history: He had a regular yearly attack of hay-fever in August, but had otherwise always enjoyed excellent health; last November (1878) had suddenly an attack of hiccough, which was followed by some indigestion. He lost his appetite; gas accumulated in the intestines, and the food regurgitated. After this attack he felt better, but at times had dyspeptic symptoms, with acidity of stomach and some constipation. He has excellent normal teeth; eats slowly, and chews well, which proves that his ailment is not the consequence of insufficient mastication. Within the last month has lost flesh.

February 7th.—On examination no tumor is found; all the organs in the abdominal cavity appear healthy; no pain or even soreness is present. Deglutition is not impaired. On auscultation of œsophagus nothing abnormal is found. Has no distress after meals. All he complains of is flatulence, sometimes acidity, and occasionally a regurgitation of solid food. For this reason he avoids solid articles. The tongue is a little furred. Cancer was suspected, but no certain diagnosis made, on account of the symptoms not being distinct enough. During the month of February the treatment with various medicines had no positive results, the patient changing for better and worse alternately. He took his meals with appetite, but all he ate was not sufficient to keep up his normal weight; on the contrary, he lost flesh and felt weak.

March 1st.—In addition to his meals, rectal alimentation was added, principally with Leube's beef solution, prepared by F. Hoffman.

In consultation with Dr. A. Flint a positive diagnosis of carcinoma was made, notwithstanding that no tumor could be felt.

From end of March until death he failed gradually. At times he had good appetite, and enjoyed different kinds of solid food; at others he could not swallow anything, everything regurgitated. Most of the time his diet consisted of stimulants, milk, essence of beef, milk-punch, champagne, oatmeal, and three to four rectal alimentations daily, with Leube's solution. The last has done excellent service, and it may fairly be said, kept him alive two months beyond his natural lifetime. He felt comparatively comfortable, never had any pain, but nevertheless was failing. He was sitting up in his chair until sixteen hours before his death, which occurred, June 23d, from asthenia.

The post-mortem was made twenty-four hours after death, with the kind assistance of Dr. A. M. Jacobus.

Dr. Jacobus made a microscopical examination, and gave the following report:

Upon examining a teased, fresh specimen of the growth, removed from the œsophagus and stomach of Mr. —, this morning, I find all the usual varieties of large cells—*i. e.* round, oval, fusiform, caudate, polygonal, etc.—which abound in a hard cancer. Many of the cells contain molecules of fat, and are undergoing retrogressive changes. Though the specimen is a teased one, there can be seen alveoli surrounded by an extensive fibroid stroma, each alveolus containing cells as above mentioned. There are also some larger or epithelial cells. Upon these facts, as well as the general appearance and chronicity of the growth, I base my diagnosis, and believe it to be a scirrhus œsophagi. Respectfully,

DR. A. M. JACOBUS.

ANOMALIES OF SPERMATIZOIDS.

DR. C. HEITZMANN directed attention to the following facts, which he had observed in examining specimens of urine. In one case urine was brought from a man who, in consequence of long-continued loss of sperm through unsexual intercourse with a woman, became impotent, and suffered from spermatorrhœa. The urine contained a large amount of spermatozoids, which, instead of having the oblong, broad head, and beneath this the two lateral thickenings (the latter being a common occurrence on human spermatozoids), exhibited a thin head, surpassing the tail in width very little only. The motion of the tail is evidently due to contraction of the living matter, which builds up the head in the shape of a reticulum, and is connected with the tail, like as the cilia are in ciliated epithelia. In the case under consideration, motion of the tails was completely absent, though the urine was freshly passed. The case would indicate a local exhaustion of living matter in the testicles, produced by long-continued over-production.

In a second case the urine contained a large amount of pus-corpuscles and spermatozoids. The latter could be traced in all stages of transition into pus-corpuscles. There were spermatozoids with both moderately and much enlarged heads, and pus-corpuscles with single tails—motionless—fully corresponding in size to those of spermatozoids. Not infrequently two pus-corpuscles were connected by means of a single tail, and in the midst of the tail there was present a larger granule of living matter. The question, whether a mere immigration or a real transformation of spermatozoids into pus-corpuscles had taken place, could be satisfactorily settled in favor of the latter occurrence. The disease, although the patient had been examined repeatedly by surgeons both abroad in this country, never was recognized until a single, thorough microscopic examination allowed the diagnosis: suppurative, or new-growth (perhaps polypus) in one of the spermatic vesicles. This diagnosis was afterward fully corroborated by the attending surgeon, Dr. L. Weber.

Dr. Howe asked Dr. Heitzmann if he believed the movement of the spermatozoid due to contraction of the reticulated structure which he had described as existing in the head.

DR. HEITZMANN replied that he did.

Dr. Howe asked why the contractions did not produce changes in the shape of the head, the same as they produced changes in the shape of the white blood-corpuscle.

DR. HEITZMANN replied that change in shape did not necessarily follow, because the living matter at the same time had given to the head a firm covering, which prevented it from changing its shape. It was like the nucleus generally, which did not change its shape, although the matter in the cell-body was constantly modifying the external outline of the cell. The white blood-corpuscle changed its shape because its cell-membrane was so exceedingly thin.

DR. J. C. PETERS remarked that Cohnheim and others recognized change in the form of the nucleus.

DR. KEYES remarked that, while he did not question the observation of transformation of spermatozoids into pus-corpuscles, he regarded it as a peculiar degeneration of the testicle that was accompanied by sweating of pus through the *vas deferens*.

DR. HEITZMANN remarked that the spermatozoa, as usually seen, had no such shape as those which he had described. In the testicle their form was very much different. There they were simply compact

formations—large granules with a relatively indefinite tail. The mature condition of the bodies we did not see, except in the seminal vesicles.

Dr. KEYES remarked that he regarded it as *prima facie* evidence that a patient had disease of the seminal vesicles when a gelatinous mass of material, having pus-corpuscles entangled in its meshes, was expelled from the urethra. Those cases usually were not diagnosed. His method of examination in a suspected case was to have the patient urinate; then introduce the finger into the rectum, and press upon the vesicles from behind forward, and then have the patient urinate again, and catch the first tablespoonful discharged. In that manner he had been able to obtain spermatozoa with pus-corpuscles, when otherwise such evidence was lost.

TAPE-WORM.

Dr. E. H. M. SELL presented a specimen of tapeworm that had been removed by the following plan of treatment:

℞. Pumpkin seeds	℥ xx.
Sugar	grs. cc.
Ethereal ext. of malefern	℥ ij.
Decoction of pomegranate root	℥ x.

M.

Ten grains of calomel were administered, after which the patient fasted for twenty-four hours, taking nothing except slippery-elm tea. One-half of the above mixture was then given in four equal doses, at intervals of fifteen minutes, and, if it did not produce catharsis within two hours, prompt purgation was produced by either castor oil or rochelle salts. By that plan he had never failed to remove the parasite. The second dose was to be given in case the first was rejected.

The Society then adjourned.

Stated Meeting, June 11, 1879.

Dr. J. W. HOWE, VICE-PRESIDENT, IN THE CHAIR.

INFANTILE UTERUS.

Dr. HEINEMAN presented an undeveloped uterus removed from the body of a girl, *æt.* 17 years, who was otherwise well developed, with the exception of entire absence of mammary glands and hair on the mons veneris, and who died in consequence of an injury. The woman had evidently menstruated, because a recent corpus luteum was found, and fully developed Graafian follicles.

INDENTATION OF THE ILEUM, WITH DESTRUCTION OF THE PERITONEAL AND MUCOUS COATS.

Dr. Heineman presented a second specimen in favor of Dr. Erskine Mason.

Henry Damm, 45; Germany; widower; cooper; entered Roosevelt Hospital June 1, 1879. Has had a small oblique, inguinal, reducible hernia for twelve years. Two months ago Wood's operation for radical cure was performed. Had no subsequent trouble with the hernia until three days ago, when it again entered the sac, and since has been irreducible.

The following morning he began to suffer from pain in abdomen, which has continued with increasing severity. Vomiting frequent, but not stercoraceous. Bowels moved freely yesterday. No urine passed for last twelve or twenty-four hours.

On examination, a small globular tumor as large as an orange, was found occupying right side of scrotum above the testicle; tumor was dull, almost flat on percussion, very tense and distinctly fluctuating. He

complained of severe pain in abdomen, which was slightly tympanitic, and very sensitive to pressure.

Operation by Dr. Mason. Taxis failing, the sac was opened, a narrow constricting band found in the body of the sac situated half an inch below external abdominal ring, which was divided, and a small knuckle of healthy appearing intestine readily reduced.

June 2d.—Pain; tympanitis increasing; respiration 32.

June 3d.—Dyspnoea; abdomen sensitive to pressure; pulse feeble, rapid, 160; patient sinking.

June 3d.—Patient died at 4.30 A.M.

Autopsy, June 3, 1879.—Brain not examined.

Heart: Slight thickening of aortic and mitral valves.

Lungs: Old adhesions, well marked congestion of lower lobes of both lungs; emphysema and chronic bronchitis.

Spleen and kidneys normal.

Moderate amount of turbid serum in peritoneal cavity, with fibrin and pus coating the peritoneum everywhere, but most abundant between liver and diaphragm.

Intestines: Stomach and intestines distended with gas; peritoneal surface congested, and coated with fibrin and pus. Near termination of small intestine a portion of ileum was found with thickened peritoneal surface, the seat of old and repeated attacks of inflammation. A knuckle of ileum about eight inches from ileo-cæcal valve had been recently incarcerated and strangulated in hernial sac. This was not gangrenous, had been wholly replaced in peritoneal cavity, and was slightly adherent to the edges of the sac by recent adhesions.

The cavity of the sac was narrow, but pervious down to its end in the scrotum. The strangulated portion of ileum presented a well-marked indentation on both peritoneal and mucous surfaces.

Dr. Heineman remarked that the two points of interest in the specimen were: *first*, the condition of the hernial sac of Wood's operation; and *second*, the condition of the intestine with its indentation, and destruction of peritoneal and mucous coats. How was destruction of the internal and external coats of the intestine at the same time to be explained?

Dr. LANGE remarked that while peritonitis was doubtless the cause of death in this case, there were many cases in which death occurred after herniotomy, because of reflex paralysis of the heart produced by tympanitis. In such cases there was *no* high temperature, but rapid small pulse and rapid respiration.

Dr. Lange then referred to a case in which those symptoms were present, and the life of the patient was saved by puncturing the intestines and allowing the gas to escape.

Dr. Howe thought the indentations in the intestine could be explained by the fact that stricture having lasted for some time, ulceration of the mucous surface occurred as a necessary consequence.

Dr. HEINEMAN thought that Dr. Howe's theory did not explain the indentation in the peritoneal coat of the intestine.

Dr. ERSKINE MASON remarked that, so far as he knew, this was the first case in which strangulation of the gut had occurred after Wood's radical operation for the cure of hernia. He had seen strangulation occurring after other methods of operating.

In the present case the patient was operated upon for radical cure about three months ago, and there was no return of the hernia until three days before strangulation occurred. Probably the operator regarded the operation as a perfect success; but the final result showed that in all operations for the radi-

cal cure of hernia there was danger that the sac might not be entirely obliterated—simply a partial obliteration. If that was true, the patient was left in a more dangerous condition than he was in previous to the operation, providing he did not wear a truss. Here was a sac which was constricted at a point from one-half to an inch below the external ring, and the constriction was of the same form as that which occurred in patients who had worn a truss for a long time.

Three days after operating upon the patient from whose body the specimen presented was taken, he was called to operate upon another man who had worn a truss for twenty-five years, and the constriction was in precisely the same locality, and the sac was in a precisely similar condition. In one case the constriction was made by Wood's method, and in the other by the pressure of the truss.

OSTEO-MYELITIS OF THE HUMERUS—EXSECTION.

DR. LANGE presented a patient who, last September, was attacked with osteo-mylitis affecting the upper part of the right humerus. At the same time the region of the left hip became painful and swollen; but in that place the disease resolved. In the humerus the disease progressed, and the patient had high fever for several months.

Dr. Lange saw her about five weeks after the beginning of the difficulty, when several incisions had been made and the shoulder-joint was in a condition of suppuration. For three months altogether the patient was confined to her bed, became emaciated and feeble, and several weeks were required to get her into a condition proper for an operation.

The operation, when performed, consisted of excision of the entire articular surfaces of the shoulder-joint, and at the same time necrotomy. It was done bloodlessly and antiseptically. He was surprised not to find a large sequestrum, and only a superficial one near the insertion of the deltoid muscle. The head of the humerus was fastened in the glenoid cavity by bony growth, so firm that he was obliged to use a chisel and hammer to remove it. The operation was not followed by fever, and two weeks after, the patient left her bed. The wound healed entirely by first intention, except where a drainage-tube was introduced, and then discharged only a small quantity of watery fluid. The operation was performed six weeks ago, and passive motion had been commenced, aided by galvanism. The formation of a new head of the humerus was apparently very good; and perhaps the good result was in consequence of preservation of the upper part of the tubercles of the bone and the insertion of muscles.

The interesting points in the specimen of bone removed were, that the epiphyseal cartilage was entirely destroyed, except at two places; the cancellous tissue had large spaces in it; the medullary canal was enlarged opposite the epiphyseal line. There was rarefying osteitis, and at the same time ossifying periostitis. The medullary canal was filled by firm, dense, fibrous tissue, which sent tender processes into the spaces in the cancellous tissue. In the central parts were yellowish spots which looked like pus; but no pus was present, and only large fat-cells, together with large cells filled with fatty corpuscles—giant-cells—together with blood-vessels.

In this connection Dr. Lange referred to a case in which, by microscopic examination, micrococci and bacteria were found in the pus in such abscess without external opening. The pus for examination was obtained by means of a needle.

(To be continued.)

Correspondence.

THE EXPERIENCES OF A SUCCESSFUL PRACTITIONER.

I.

THERE are some physicians who believe that the Code of Ethics was made solely for the benefit of the older members of the profession who have secured a position. I used to think so when I was younger. Now, I believe that the next thing to looking after your own interests and seeing that you have a fair show in the race for professional success is to stand up for medical ethics through thick and thin. Without shocking any personal modesty, I may say that I have followed out this principle with a good result. There is such a thing as being charitable to your brother, and if you can only show that charity to advantage before a third person, you are quite sure to benefit yourself, especially if the third person is in need of medical advice. But all the while you must keep a single eye to the glory of the Code, and recollect that he who plays with fire must have a long reach. As I said before, I never lose any opportunity of speaking well of a professional brother when I am accidentally called to see his case. To this, in fact, I owe most of my success in practice; for not only will his patients force themselves upon me, but he will call me in consultation to others. As there are not a few who would like to know how this is done, I may perhaps flatter myself that a little detail of personal experience may not be uninteresting. By way of premising, let me say that I am particular to cultivate younger men and help them along in practice as well as I can. To illustrate this particular point, I will refer to an instance or two that occurred in the earlier practice of Pine Ridge, which showed the benefits of my magnanimous spirit.

One morning, in driving through the village, I noticed the bright new sign of Dr. White. I smiled an inward satisfaction, and resolved to be his friend. At once concluding that I had more business than I needed, and that there was plenty of room for the new man, I resolved to call on him and welcome him to the town. This was done, and, to my surprise, he stated that he had not been led to expect such courtesy. The evening passed pleasantly, and, notwithstanding we were interrupted by my servant with fifteen calls for me, to which I must attend before retiring, the festivities were kept up until a late hour. As I left him I just happened to think of my patients, when he pitied me and charitably wished himself in my place. His young and innocent smile appealed to my heart, and soon after, when dropping to sleep on my couch, and thinking of his surprise at my fifteen extra patients, I resolved to be his friend. As he was working principally for a reputation, I commenced my good deeds by recommending to him such chronic cases as I did not want, and who could not pay. I introduced the first patient by note, and received a gracious and appreciative reply, which hangs, duly framed, in my office. But this is by the way.

I dropped in every now and then to see him, and he being always in, I seldom lost the opportunity for a quiet and confidential talk. He was well prepared to practise, having studied two full years and attended in that time four courses of lectures, received two prize medals and a certificate for a month's attendance on a post-graduate course. My soul warmed at the op-

portunities I should have of recommending him accordingly to some of the good-paying patients I should send him. It may be well to state here that, at the outset of my acquaintance with him, I made him a present of a copy of the Code and secured his membership to our county society, thus ensuring his professional standing. Need I say that, with all these advantages, the young man succeeded? He did. Is it a wonder that I should be gratified? Hardly. And could I be blamed for giving him help when he did succeed? But I proceed with my illustrations, and as details of cases are sometimes more instructive than generalities, I make no apology for introducing one or two here.

One summer afternoon I was driving past Smith's, and was asked by Mrs. Smith to look at her son Harry. Notwithstanding I was in a great hurry, and had to visit thirty patients before supper, I consented to see the patient. I at once told the mother that the child was very sick; that it had evidently been left too long without proper treatment, and chided her for neglecting to send for me before. When she informed me that Dr. White was attending the case, I at once became mortified at my indiscretion, and, for a time, could not see my way clear to vindicate my brother's good name and uphold professional honor. Of course, I at once backed down, and openly confessed that I did not know that Dr. W. was in attendance; that he was a good fellow, a friend of mine; that I was sorry I had said anything against him; that he was probably right—at least, I hoped so; that it was against our Code of Ethics to criticise each other's treatment, to destroy the confidence of our patients, or in any way strive to replace each other. The child vomited at this time, and I arose to retire, declining to have anything to do with the case until Dr. White should be sent for. The appeals of the mother brought me back, and I held the child's head. At the same time I whispered words of kindness in his ear. I informed the mother if it were my case I should have the child seen to at once, and urged her to send for Dr. White. I found a good opportunity to say to her that Dr. White, although a very young man, with but little experience, was remarkably apt; that although he was brought up as a carpenter, he had learned the science of medicine in two years, and that such enterprising men should be encouraged. Politely declining to have anything more to do with the case, I gracefully retired, promising to stop myself and send Dr. White around. I did so, telling him what good service I had done him, and how necessary it was in all our relations to prevent ill-feeling and jealousy by sticking to the Code and acting squarely with each other. I heard no more of the case until that evening, when I was summoned to meet Dr. White in consultation. I informed the father who summoned me that I was very much pressed for time, but that I would, nevertheless, do all I could to help my friend White.

Having arrived at the house, Dr. W. examined the patient first, but quickly yielded to me. Anticipating that the case would be a difficult one for diagnosis, I had brought all my instruments of precision with me. Unfortunately Dr. White had none of these, but I believed it to be my duty to give the patient every chance. I examined the eye with the ophthalmoscope and demonstrated to Dr. W. and the father of the child the commencement of a choked disc. Dr. W. had never seen such a thing before, and he was honest enough to say so before the family. The ear speculum showed a slight opacity of the tympanum due to thickening around the malleus and slight œdema over

the site of the tensor tympani muscle. The laryngoscope disclosed patches behind the uvula and a slight paralysis of the right vocal cord. The cephalic temperature was slightly increased ($\frac{1}{10}$ of a degree) over the right or affected eye. A slight aortic murmur, a crepitant r le, at the base of the lung proved the value of a stethoscopic examination. The liver was normal, but, on account of the relaxation of the umbilical ligament, hung a little low. Thermometer in the rectum marked 101° F. Urine collected to be afterward examined. Tested on the spot by a urinometer, much to the satisfaction of the father, who was pleased with the delicate action of the instrument.

The rectum being examined, some ascarea vermiculares were found, indicating a faulty nutrition of that point. The worms were slightly asphyxiated. Unfortunately, Dr. White had not examined this part of the body, a fact for which he was quietly blamed by the mother, who said from the first she "thought it was worms." I politely informed her that the doctor had done everything that was really required, and that my examinations were necessary only for the sake of clearing up any doubtful points. In fact, it was only called for on the ground that experience had taught me that it was best to be on the safe side. The child having some diarrh a, I asked to see the passages, remarking casually that now we should have a clue to the whole trouble. The mother had not saved the passages. Unfortunately for me, before I thought, I asked the doctor what was their character, and he was forced to reply that he had not examined them. Determined to shield the doctor, I changed the subject by remarking that after all it might not have been of any importance, only I should like to have seen them for my own satisfaction—a matter so purely selfish that I was forced to smile as I referred to it. I forgot to mention that the prepuce of the child was slightly elongated; that he had a strong liking for sugar and peanuts; and was occasionally peevish when crossed.

While I was washing my hands the father was examining my instruments and asking the doctor all sorts of questions as to their use. I confess I was somewhat surprised at the latter's ignorance, and made an excuse to give the necessary explanations. This was done more to turn the subject of conversation than for any desire to satisfy the inquisitive parent.

After tucking Harry under the chin and bidding good evening to the parents I retired with the doctor for formal consultation. We agreed that it was a simple case of intestinal irritation, and I suggested a change from rhubarb and soda to chalk mixture well sweetened and highly flavored. But, said Dr. W., "How about the choked disc?" I replied that such, as well as the aortic murmur and increased cephalic temperature, was due to a slight congestion of the pons varolii which was reflected through the vasomotor system of those parts. He was satisfied, and thought it best to give such a diagnosis to the mother. I agreed, but he became confused in his explanations and I had to help him out. While Dr. W. was in with the child prescribing the new medicine, I started to go, when the father waylaid me in the hall asking all sorts of questions about the case. I informed him that the child would probably get better now; that Dr. W., who although young was willing to learn, had agreed to change the medicine, and that if he was careful in studying the new symptoms he would not need any further assistance. While doing this I impressed upon him the fact that I was a great friend

to Dr. W.; that he was an exceedingly apt scholar, and, for his opportunities, he was the safest doctor of his age that I knew. Just then the doctor came out of the room, and I kindly put my arm in his, we walked out together, and I confidentially informed him that although his position was a little shaky in that family, I had done my best in accordance with the Code to hold up his hands and say what I could for him as a professional brother. He thanked me, and we parted on the corner.

When I arrived at my office the father of the child was waiting for me. He requested me to see the patient again that night. The child had vomited since the visit, and the parent did not believe that Dr. W. understood the case. In fact he desired me to attend it henceforth. This at first I flatly refused to do, but how I managed it afterward, to the satisfaction of all hands, will be seen in my next. * * *

PINE RIDGE ON THE HUDSON.

SYPHILITIC PERIOSTITIS OF THE CRANIUM.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The following case occurred during the past winter, and was treated in the wards of the U. S. Hospital at Jefferson Barracks, Mo., by Surg. E. P. Vallum, U.S.A. The subjoined is a synopsis of the history, symptoms, and treatment:

Select recruit W— presented himself at "sick-call" on the 23d of Jan., 1879, and requested that something should be done to relieve him of a sharp, lancinating pain, which began above the left eye and extended backwards in the course of the temporal ridge. There was an absence of swelling, and but slight tenderness on pressure could be detected. This being his first attack, and several cases with like symptoms and of malarial origin having been previously treated successfully with large doses of quinine, and hypodermics of morphia at the seat of suffering, he was put on a similar line of treatment. This, however, did not bring about the results which had been anticipated, and on Jan. 26th he was admitted into the hospital, the pain still continuing with unmitigated severity. The hypodermics afforded only temporary relief, and the quinine had apparently no effect in promoting a cure. The pain, which was at first sharp and neuralgic, was now also at times dull and gnawing. In addition, a swelling had shown itself over the affected area, the left temporal region being much fuller than the corresponding surface on the opposite side. The swelling was but slightly tender, and was firm and hard to the touch. The left eye was perfectly normal in appearance and in function. The treatment for several days after admission remained unchanged, except that small blisters were applied to the tumefied surface, which was afterwards dressed with simple cerate and morphia. No improvement followed, and ferri et quiniæ citrat. was substituted for the quinine, the hypodermics and blisters being kept up. This course of treatment was pursued till Feb. 9th, without influencing the malady in the slightest degree. The pain was fully as agonizing as at first, and was continuous, with paroxysms of great severity in the latter part of the night and in the early morning hours. Much sleep had been lost, and the general health was beginning to suffer, despite the employment of the tonics mentioned, and the allowance of a generous diet. A careful inquiry was now made to learn something of the previous health of the patient, and it was ascertained that he had suf-

fered from primary syphilis *ten years* before; but, as no constitutional symptoms had ever shown themselves, he had always considered himself perfectly cured of this trouble. He at that time resided in New York City, and was attended by two physicians—one of them a distinguished author and authority on venereal diseases—both of whom pronounced the initial sore a "chaneroid." Suppurating buboes followed in both groins, though efforts were made to abort them with iodine and blisters. A purely local treatment was adopted throughout, and an apparent cure resulted in a couple of months. After obtaining the foregoing history, our patient was put on a specific treatment, consisting of hydrarg. proto-iodid., and pot. iodid., in alternation. The ferri et quiniæ citrat. and the blisters were continued, the abraded surface of the swelling being dressed with ungu. hydrarg. Immediate improvement was noticed, and no change in the treatment was made from that date (Feb. 9th) till his discharge from the hospital "cured" on March 23d. All pain and tumefaction were now gone, and the general vigor of the body was almost restored, the patient remarking that he felt "perfectly well." An examination instituted to determine whether or not any evidence of syphilis existed in the bones or viscera, gave negative results. No nodosities were discovered in the clavicles, sternum, or tibiæ; and the glands behind the elbow and the neck exhibited no appreciable enlargement. Eruptions on the skin and sore throat had never occurred, and iritis and alopecia had not at any time been experienced. Still, despite these facts, I think that the syphilitic nature of the affection was satisfactorily made out; and though ten years had elapsed since the occurrence of the primary sore, I feel quite confident that the relation between it and the recent outbreak was that of "cause and effect." Finally, when we remember that it was a "chaneroid," which many syphilographers say never produces secondary or tertiary manifestations, but which evidently in this case was the remote but potent factor in causing systemic infection, we look upon the case with increased interest, and consider it of sufficient rarity to merit this report.

I am, very respectfully, etc.,

JOHN J. KANE,
Asst. Surgeon U. S. Army.

NOTES ON A CASE OF EPILEPSY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—S. P.—, colored girl, age twelve, well-grown and robust, native of Virginia, and raised on a farm in a section where epilepsy is rather frequent. Epileptic paroxysms commenced at the age of eight, at the rate of one in two weeks, generally at night; gradually increasing in frequency until April 1st, when they averaged four per day. At that time there was a very free flow of saliva and considerable mental dulness; both had commenced and gradually increased with the paroxysms. In other respects there was nothing to note, the patient "enjoying good health." In this case the "aura" was well marked, and by grasping the arm tightly the seizure could be checked.

The case had been under the charge of two prominent country practitioners and had received the usual treatment, especially that of bromide of potassium, with no favorable result, and had been given up as hopeless, as "she had experienced more than five hundred seizures."

I concluded to make trial of bromide of potassium

in combination with hydrate of chloral, using just enough of the hydrate to strengthen and cause the bromide to act promptly. I had used this combination with excellent results in cases of wakefulness where the bromide had ceased to act.

April 1st the patient commenced taking the following:

B. Bromide of potassium..... ʒ ij.
Hydrate of chloral..... ʒ ij.
Water f ʒ vij.
M.

S. Half-teaspoonful on rising and retiring, the dose to be doubled at the end of first week.

Up to July 1st the patient had experienced only three paroxysms, two of these occurring in the first week after commencing the treatment. At that date the mind was much improved and the flow of saliva had decreased to near normal, while in other respects the patient was in excellent health.

Such a favorable result is remarkable, and I make the report at this early date in order to draw out others who may have used the combination, or else induce others to make trial of it. I would like to have of its trial in cases of the petit mal.

Very respectfully,

J. A. TANNER, JR., M.D., U.S.A.

HARRISON SQUARE, BOSTON, MASS.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 17 to August 23, 1879.

PERIN GLOVER, Lieut.-Colonel and Surgeon, Medical Director of the Department. Granted leave of absence for one month on surgeon's certificate of disability. S. O. 160, Dept. of the Missouri, August 20, 1879.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending August 23, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Aug. 16, 1879.	0	18	37	4	28	14	5	0
Aug. 23, 1879.	4	12	34	6	26	10	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from August 19th to August 26th, inclusive, was 203, and the number of deaths that occurred was 59. The total number of cases for this year to August 27th is 778, and the total number of deaths 217.

PRIZE ESSAY ON DIPHTHERIA.—Her Majesty, the German Empress and Queen of Prussia, offers a prize of 2,000 reichmarks (\$480) for the best essay on "the essence of diphtheria and the results of treatment of the disease based upon knowledge of the nature of the affection." The prize will be given only

for such work as contains important new facts regarding the essence of the disease, but particularly concerning its mode of propagation and the prevention of the same. The essay may be written in German, French, or English, and must be forwarded to B. von Langenbeck, Professor, Berlin, N. W., 3 Roonstrasse, before the first of December, 1880. The prize will be awarded at the first meeting of the German Surgical Congress in April, 1881. Each essay must be marked with a motto, and the same motto must be placed upon an accompanying envelope that contains the author's name.

The committee consists of Professors Klebs, of Prague; Liebreich, of Berlin; von Nügel and Oertel, of Munich; Thiersch, of Leipsig; Virchow, of Berlin, and von Langenbeck, of Berlin.

ROUTINE USE OF THE OPHTHALMOSCOPE IN CEREBRAL DISEASE.—Dr. J. Hughlings-Jackson asserts in the *Medical Press and Circular* that there is nothing in medical ophthalmology more important than the fact that a patient who has acute neuritis can read the smallest type and may not know that his sight is in any way defective. This claim he has made for several years, and now presents many authorities to support it. As a consequence of the fact, he urges the necessity of a routine use of the ophthalmoscope, lest the disease be overlooked in its early stage, and we lose an important help in diagnosing other pathological changes.

A NOVEL METHOD OF CONTROLLING HEMORRHAGE IN AMPUTATIONS OF THE HIP has been introduced by Mr. Davy, of London. It is done by means of a wooden lever about two feet long, measuring an inch in diameter at either end for six inches of the length, and being only four-fifths of an inch in diameter for the remainder. It is turned perfectly smooth, the ends being well rounded. It is introduced into the patient's rectum sufficiently far for the end to rest in the hollow opposite the sacro-iliac synchondrosis, between the psoas muscle and the base of the sacrum, where it is made to rest on the common iliac artery, controlling the blood perfectly. It has been used successfully four or five times.—*Chicago Med. Journ. and Examiner.*

INFLUENCE OF MARRIAGE UPON HEALTH AND MORALITY.—Dr. Bertillon, a French savant, has published some very interesting statistics in regard to the influence of marriage upon the human race. He has studied the mortality bills of every country in Europe, so that his figures are more exhaustive and his conclusions more striking than any previously published.

He finds that "a bachelor of twenty-five is not a better life than a married man of forty-five; that among widowers of from twenty-five to thirty the rate of mortality is as great as among married men of from fifty-five to sixty." In other words, celibacy ages a young man at least twenty years, and widowhood still more. In France the rate of mortality among married men, between twenty and twenty-five years of age, is ten per thousand, and among bachelors of that age sixteen per thousand, and among widowers nineteen per thousand.

In regard to criminal acts, these occur about 50 per cent. oftener among bachelors than married men, and 25 per cent. oftener among spinsters than married women. Suicide is also much less frequent among the married. In fact, all the statistics show very conclusively that the married state promotes health, long life, and morality.—*Lancet.*

DIPSOMANIA AND DRUNKENNESS.—Dipsomania is a disease of the nervous system, akin to epilepsy and

insanity. It implies a degeneracy of the intellect; hereditary influence has a large share in its production; in it there is generally a complete abolition of the moral sense, as shown by lack of shame, unrestrained licentiousness, deceitfulness and broken promises; it occurs sometimes as an acute disease, it often appears in periodical attacks like epilepsy, but it most frequently exists in a chronic form. It occurs oftenest amongst the higher classes, and champagne is of all drinks the most active as a cause; and drunkards, on the other hand, are persons who when they drink do so to a complete state of intoxication, but when they recover, are wretchedly ill and quite conscious of their moral wrong. They yield rather to external temptations than to internal cravings. They generally come from the lower classes.

In treatment the above distinctions should be regarded. Dipsomaniacs should be treated as insane persons, and the State should take charge of them. They should be committed to asylums for a year at least, and if possible for three years. There is but one way to obtain a cure, and that is the absolute withdrawal of alcohol. The only drug of any use is bromide of potassium.—*The Practitioner*, June, 1879.

THE CÆSARIAN OPERATION IN LOUISIANA.—Dr. R. P. Harris has recently collected, with much care and trouble, records of all the operations of gastro-hysterotomy that have occurred in Louisiana, and the statistics give a very favorable showing for that State. Nineteen cases are reported. Of these, 73 $\frac{1}{2}$ per cent. of the women, and 42 $\frac{2}{3}$ per cent. of the children were saved. In six instances the operation was performed early, and here all the women and four of the children recovered. In ten cases where labor was prolonged three women and all the children died. These statistics are particularly valuable in showing the real mortality of the operation, because they include all the cases and not those alone which had previously been published. The danger in drawing conclusions from the cases voluntarily put on record is shown by the fact that of the 108 collected cases in the United States only 62 have even been published, the remaining being, of course, often fatal ones. The statistics given show that about three-fourths of the women and two-fifths of the children recover; also that the early operation is very much more favorable both for mother and child.—*N. O. Medical and Surgical Jour.*

MUSCLE-BEATING IN INFANTILE PARALYSIS.—A muscle-beater manufactured at St. Petersburg and on exhibition at Paris, has been introduced into some orthopedic establishments as a supplement to massage. Besides this instrument, which is called Klein's muscle-beater, there are employed oval palettes four inches long, two and a half inches wide, covered with velvet and attached to a handle seven inches long. Two of these are used, striking the limb alternately. The palettes are better than the Klein's muscle-beater, but neither will take the place of rubbing.—*British Med. Journ.*

THE PURE RUBBER BANDAGE.—In a letter to *The Lancet*, Dr. H. A. Martin reiterates his claims for the rubber bandage in the treatment of chronic ulcers. There are few, we believe, who have tried them who have not met a good deal of disappointment, and anything but uniformity in the results. At some of our city hospitals it is roundly asserted that those who attain such extraordinary successes mistake granulation for cicatrization. Dr. Martin contends, however, in his letter, as he has done elsewhere, that failures are due to the use of ointments and washes

with the bandages, or to the bandages themselves being improperly made. The most injurious, and perhaps most frequently used wash is one containing carbolic acid. And this drug is also employed in making many of the bandages, especially the English ones. The bandage should be composed of pure rubber, with the minimum amount of sulphur necessary to vulcanize it. Dr. Martin is undoubtedly right in discountenancing the employment of the various irritating washes and applications. To claim, however, that with the pure gum the days of the chronic ulcer are over, is going much farther than facts will justify.

NEW REMEDIES.—Dr. J. J. Mulheron, of Detroit, gives additional testimony to the value of eucalyptus globulus in subacute cystitis. He uses it in doses of ℞xx. of the fluid extract every four hours. Dr. A. S. Rockwell, of New York, reviews the history of *Viburnum prunifolium*, or black haw, and as the result of the experience of others and himself, endorses its use in certain kinds of dysmenorrhœa. The cases in which the drug is indicated are those of delicate nervous women, in whom the pain is due to slight flexions, slight endocervicitis, partial stenosis, or where it is neuralgic in character. Black haw may be classed as an anodyne antispasmodic and tonic. It is given in infusion, tincture, or fluid extract, the dose of the latter being about ʒss. every one or three hours.

Dr. John B. Rice relates a case in which the tincture of *Thuja occidentalis* seemed to cure a case of epithelioma of the lip. The patient took fourteen drachms daily. This drug was first brought into prominence by Dr. J. R. Leaming, of New York, in 1877, and he has had similar successful results in his own practice. It is not pretended that it is always a specific, but it seems to be often very beneficial and occasionally even curative in these affections.

The new laxative *Cascara sagrada*, about which there has been much quarrelling in western journals, seems to be taking its place as a tolerably useful remedy.—*New Preparations and Mich. Med. News.*

HYDROPHOBIA.—The repressive measures usually adopted by municipalities to prevent hydrophobia are those, according to Dr. Blatin of Paris, most likely to cause the disease. This is especially true of muzzling dogs. The practice of killing dogs the moment they are suspected of being mad is still more absurd. It is stated by the Council of Hygiene of Bordeaux that the premonitory stage of rabies is harmless. It is known that mad dogs live but seven days, which is not a very long time for the bitten person to wait in order to learn with certainty his fate.

ST. LUKE'S HOSPITAL.—Dr. Beverly Robinson has been appointed Visiting Physician to this institution, to fill the vacancy caused by the resignation of Dr. Wm. M. Polk.

LESSONS IN GYNECOLOGY.—Our attention has been called to an error in the review of Dr. Goodell's "Lessons in Gynecology." The reviewer says, "nowhere has even mention been made of the name of Emmet," etc. This is an error which we cheerfully correct by directing attention to page 182, where the parenthetical sentence, "Emmet, to whom we owe all we know about the operation," etc., can be found.

SPASMODIC INFANTILE PARALYSIS— SPASMODIC INFANTILE HEMIPLE- GIA.

A CLINICAL LECTURE DELIVERED AT THE PHILADEL-
PHIA HOSPITAL.

BY CHARLES K. MILLS, M.D.,

NEUROLOGIST TO THE HOSPITAL.

(Prepared for THE MEDICAL RECORD.)

GENTLEMEN:—The affection to which I will first call your attention this morning is a form of infantile pseudo-palsy, of which you will find little or nothing said in your text-books. Cases reported in journals have also been few, although the spasmodic spinal paralysis of adults has been largely discussed by neurological contributors during the last few years.

B. D., *æt.* 4, is a little boy from the children's asylum connected with the Hospital. As nothing is known of his relatives, no previous history can be obtained, and we will have to be contented with a study of his present condition.

He has a fair-sized head, but it is flattened a little more than usual from the vertex forward. The fontanelles are closed, but the lines of the sutures are projecting and rough. Both pupils are dilated, and, according to the nurse, they are always in this state. He has left internal strabismus; he has no facial paralysis; he can protrude his tongue without difficulty, and he talks pretty well for a child of his age. He seems to have fair intelligence, but he cries and laughs on slight provocation.

His back seems weak, and tends to project backward as he sits on the chair; he has, however, no real spinal curvature. He has good use of his arms, but they show a *tendency* to flex at the elbows; they frequently get into a semi-flexed position when he is quiet, and sometimes resist extension slightly, but they are not rigid, and he can straighten them himself without special effort.

He is unable to stand alone, and if attempts are made to force him to do so he becomes much alarmed. If not held he falls at once to the floor. Supported by the hand, or from behind, he stands in a peculiar position. His legs, from the knees upward, are tightly drawn together; below the knees, they are a little apart; the heels are kept slightly elevated; the thighs are bent on the pelvis at an angle of about 120°, and the legs have about the same inclination on the thighs; the feet turn inward slightly. The flexors and adductors of the thighs, and the muscles of the calf, feel hard, and are in a condition of tonic spasm. He walks in a curious fashion, keeping hold of the hands of the nurse; his legs remain semi-flexed at the knees; he steps on the front part of his feet and toes, his heels never touching the floor. As the leg and foot of one side are advanced, they tend toward and sometimes are carried over the other limb; sometimes, as he puts forward the right foot, the toes of the left will get under the right heel, and *vice versa*; the limbs, in walking, have a tendency to become entangled; the flexors and adductors of the thigh seem to be always acting unduly; the feet are kept in a condition of slight extension and adduction.

His body appears to be abnormally long in proportion to the length of his legs. His hips are narrow, and the glutei muscles show some want of develop-

ment. The thigh and leg muscles are fairly developed, particularly the flexor groups. Electro-tractility is generally well retained. Sensibility is good. The limbs are not cold nor changed in color; the joints are free from adhesions; the prepuce is not adherent and can easily be retracted.

When he is sitting or lying down his legs can be straightened by the exercise of some force, but they immediately tend to return to their state of abnormal flexion and adduction.

Lightly tapping each patellar tendon, the corresponding foot and leg is projected quickly and somewhat forcibly forward. I can produce the same phenomenon by tapping upon the lower part of the tibia. Abruptly forcing the foot into flexion, and smartly striking the tendo-Achillis, no tremor or oscillation is set up, but the spasm in the flexors and adductors is increased.

Before discussing this curious case, I will read you the notes of a private patient, many of whose symptoms correspond closely to those of the child before you.

J. P., *æt.* 4, was apparently very healthy until three months old, when he had a severe attack of vomiting and convulsions. Several other children in the same family have had convulsions during infancy. When a year old the patient had pneumonia, during which his mother says he had "inward spasms." For more than a year after this his bowels were much constipated, never being opened without an injection. During his entire infancy he was very fretful and irritable. When he began to use his arms and legs his parents noticed that he could not grasp things properly and could not balance himself on his feet. He has never been able to stand or walk alone.

His condition has not materially changed during the six months that I have had him under observation.

He has left internal strabismus, which his mother thinks dates from birth. His face has a smooth look, the lines not being well marked. He has, however, no paralysis of the facial muscles. He can talk quite glibly and seems bright and intelligent; but it is often difficult to fix his attention upon a special subject. He usually carries his head thrown backward slightly. His back seems weak.

He carries the left arm strongly flexed at the elbow, and flexed and abducted at the wrist, the fingers and thumb being at the same time thrust apart and slightly bent backward. His right arm, forearm, and hand present the same abnormal contractions, but they are not nearly so marked as on the left side.

Both legs exhibit a strong tendency to flexion at the knees. The thighs are adducted, but not forcibly. His feet are held slightly inverted and extended, the heels being drawn upward. The flexors are spasmodically contracted.

Catching hold of some one's hands to support him, he makes a timid effort to walk. He steps on the toes and balls of the feet, his heels not coming down. The legs do not straighten at the knees. The feet are kept wide apart. The limbs do not tend to interlock or to cross one over the other, as in the other case.

The muscles generally are firm and well developed. Those of the upper, outer, and posterior aspect of the thigh are particularly large and firm. Electro-tractility and sensibility do not appear to be changed. The patella-reflex actions are rather above than below the normal, and passive dorsal flexion does not produce clonus, but seems to increase the already existing spasmodic tendency and condition.

Both legs and arms can be straightened by forcible traction, but the flexors resist the effort, and on letting

go of the limbs they tend immediately to return to their condition of spasmodic flexion.

The legs show no vaso-motor or joint troubles. The functions of the bladder and bowels are naturally performed.

Let me now sum up the chief features presented by these two cases. Briefly they are as follows: Dilated pupils and internal strabismus; slightly weakened intelligence; in one case convulsions in infancy, in the other the infantile history not known; apparent weakness of the muscles of the back in both cases; marked state of tonic spasm of the lower extremities, chiefly affecting the flexors and adductors; a similar spastic condition in the arms in one case, and a tendency to spasmodic contraction in the other; inability to stand or walk alone; tendon-reflexions increased; no paralysis of bladder or bowels; retention of electro-tractility and sensibility; absence of vaso-motor changes or joint troubles.

The positive symptoms are certainly chiefly spinal. They would seem to indicate either a congenital or an acquired want of development of certain columns of the cord. As we have no loss of sensibility, no ataxia, no trophic or vaso-motor changes, but only disturbances in the domain of motion—spasm, paresis, and increased reflex—the lesion, whatever it may be, is probably one of the motor divisions of the cord, of the lateral or antero-lateral columns. You have a disorder of infancy and childhood analogous in many respects to the spasmodic spinal paralysis of Erb, which this author tells us is almost exclusively a disease of maturity, and whose pathology is probably properly indicated by the designation primary lateral sclerosis. Erb, indeed, remarks that from various observations which he has reported it would appear that spasmodic spinal paralysis may also develop itself even in earliest childhood, and we might then imagine the possible congenital defective development of certain divisions of the spinal cord. Part of the cases described under the name of spasmodic infantile paralysis may well belong to this class. The remarkable observation communicated by Seeligmüller, where four children of the same family were taken sick with amyotrophic lateral sclerosis, should also be placed here. (*Ziemssen's Cyclopaedia*, Vol. XIII, p. 624.)

Is not the brain implicated in cases of this kind? The convulsions, lowered intelligence, strabismus, and dilated pupils might be supposed to point to cerebral involvement. The convulsions, however, may have been spinal or may have arisen from temporary causes, and intellect is not more seriously compromised than in many other children who have early lost the use of their limbs from spinal or peripheral disease. The ocular symptoms might be connected with spinal defect. You must not forget, however, the very frequent occurrence, even in the so-called systemic sclerosis of the spinal cord, of coincident cerebral lesions. You might have lesions in such cases in both brain and cord. It would not be impossible to explain the phenomena of spasm and paresis presented by these patients by a bilateral sclerosis and atrophy of portions of the cortical motor zones; but a primary spinal affection is, on the whole, more probable. Secondly, the cerebral centres of motion have, no doubt, become affected.

In St. Bartholomew's Hospital Reports, Vol. XIII, 1877, Samuel Gee, M.D., in a brief communication *On Spastic Paraplegia*, reports several cases similar in many of their features to these cases. He gives their chief characters as follows: Constant rigidity of legs, or of legs and arms, which increases when the limbs

are handled, and disappears under chloroform; the functions of the limbs impaired; the disease congenital or beginning in infancy; the affected muscles act well to faradism; the nutrition of the parts usually well kept up; general nutrition good; no tremors; intellect and sensation natural; no lesion of micturition; the back apparently weak in all cases; choreiform movements of the face occurred in two instances; in two a tendency to convulsions; painful cramps in the legs in one case. Gee gives these cases without note or comment.

Cases of spasm involving the muscles, the legs or arms, or both, somewhat similar to those I am describing, but of temporary duration, are sometimes met with among infants and children, as well as among adults. Dr. S. Weir Mitchell, in a lecture on *Spasmodic Disorders of the Legs*, published in the New York *MEDICAL RECORD* for June 28, 1879, mentions some cases of this kind, and makes of them a distinct group due to obscure functional conditions, and in which the spasms seem to be temporary, and to constitute the sole objective symptoms. One of his cases was a lad aged seventeen years, who, after exposure to intense heat, was attacked with headache, and subsequently with dull aching and extreme rigidity of the legs. The rigidity disappeared by slow degrees, and the boy was well at the close of three weeks.

Several months since, in consultation with Dr. Roland G. Curtin, of this city, I saw one of these curious cases of temporary rigidity or spasm. The patient was a girl thirteen years old. She was first taken down with pains in her limbs, apparently rheumatic in character. In a few days endocarditis developed; a mitral systolic murmur was detected. Soon, under treatment, the pains and cardiac symptoms improved greatly; but she now began to suffer from a troublesome crampulous diarrhoea. About the same time the doctor noticed a stiffness in certain muscles of the arms and legs. These rigidities increased, and were accompanied by pains and aching in the limbs and joints; I saw her nearly four weeks after their first appearance. Her arms were held semiflexed at the elbows; her hands were slightly flexed and abducted at the wrists; both the extensors and flexors of the thighs were in a condition of tension, so that her legs were kept rigidly straightened out; the heels were drawn upward and the feet inward by strong spasmodic action of the calf-muscles; so far as the symptom spasm was concerned, the condition was much the same as that of my second little patient, differing from it only in degree. Pain or soreness in the affected muscles and around the joints was, however, a symptom not present in my cases of spasmodic infantile paralysis. In this case, as in the others, by the exercise of considerable force, the muscular rigidities could be overcome and the limbs extended or flexed; but after she had been handled in this way she suffered for several hours with more or less pain in the parts manipulated. In our infantile patients, pulling and hauling at their limbs does not seem to cause any pain, either at the time or afterward. In this girl the tendon-reflexes were exaggerated. Sensation was unaffected. She suffered considerably with headache. Her appetite was very capricious. She was highly anæmic. She had never shown any hysterical peculiarities. She was placed upon the nitrate of silver and opium, the one-sixth of a grain of each four times daily, and, what is most gratifying to report, immediately began to improve. In one week she was able to stand and walk a little; in two weeks the diarrhoea and spasmodic disorder had both disappeared; her general health also became good, and

Dr. Curtin has informed me within a few days that she is now, and has been for many weeks, right well.

Dr. Mitchell, in the lecture alluded to, speaks of rigidity of the legs in children, which he believes to be associated with defective cerebral development; also of cases of spasm of the adductors of the thighs for which he has had circumcision performed, but without success. He thinks that irritation of the sexual organs is sometimes a source of adductor spasms.

I do not think, as I have already intimated, that in my cases the brain was chiefly involved, and preputial irritation had certainly nothing to do with the production of the symptoms.

In regard to the treatment of these cases of spasmodic infantile paralysis, I am sorry to say that I have nothing encouraging to advance. If a congenital or acquired atrophy of the spinal cord is at the root of the trouble, you can certainly hope for but little positive benefit from any treatment, unless new channels for the transmission of motorial impulses can be created. Nitrate of silver, and remedies of the same class, might be tried, but not with the hope of success that you would have in cases of a functional or temporary character, or even, perhaps, in spinal sclerosis occurring from special causes in adults. Something may, perhaps, be accomplished by training, by persistently striving to get the patients to throw more will into the muscular efforts which are wanting.

In the second case which I have detailed, I made a systematic trial of electricity. For six weeks, every other day I applied as strong a galvanic current as the child could bear—not a very strong one, by the way—along the spinal column. I used large sponge rhizophores, keeping one in the lower lumbar region, and putting the other first to the back of the neck, and then moving it slowly from point to point down the spine. The ascending current was employed for half the time, and the descending for the other half. No appreciable effect on the disease was produced. Still further trials with electricity might, however, be made. The general health of the patients should, of course, be sustained by attentions to diet, fresh air, etc. As pain is usually absent, narcotics are not called for, and hypodermic injections of atropia, or of atropia and morphia, are not as useful as in the spastic paralyses of adults. In the present state of our knowledge of these cases, cutting the tendons could not, I think, be looked upon as anything but bad practice, however tempting it might be to interfere surgically.

SPASMODIC INFANTILE HEMIPLEGIA.

In conclusion, in connection with the cases just studied, it may not be uninteresting to direct your attention briefly to a case of paralytic and spasmodic disease occurring in infancy, and of undoubted cerebral origin.

The patient is a little girl, four years of age. When she began to creep her mother first noticed something wrong with her left arm and leg; they seemed much weaker than the limbs of the opposite side, and she usually carried the arm slightly bent at the elbow. When two years and a half old, the child awoke suddenly one day, crying and frightened, and immediately fell over in a spasm. The convulsions affected only the left side of the body, and the movements were chiefly confined to the fingers and toes of this side. This attack lasted about half an hour, or a succession of seizures took place during this time. Her face was pale and her lips blue during the paroxysm. Every month since this first convulsion, she has had

two or three similar attacks. They are always followed by a temporary increase in the parietic symptoms in the left arm and leg.

The child, you observe, is rather small for her age, but is of good color and fair, general appearance. She talks pretty well. She is cross, self-willed, and irritable. She never complains of headache or of pains. The left arm and leg measure about half an inch less in circumference than the right limbs at corresponding points. She carries the left arm slightly flexed at the elbow, the hand, thumb, and fingers being also in slight flexion. This arm is weak, but not powerless; she can lift it to a horizontal line, and has some grip, but cannot long continue her grasp upon an object. The entire left leg is weaker than the right, but shows no contractures. The left foot tends to turn inward. Faradic and galvanic contractility are retained, but are diminished in the peronei and extensor muscles of the foot. Examination with the ophthalmoscope shows nothing abnormal.

I could quote to you from my note-books many cases similar to this. At one time they were passed by without reasonable explanation, but much light has been thrown upon them by researches in cerebral localization. Unlike the other cases of which I have just spoken, the spasms in this patient are clonic, are accompanied by unconsciousness, and are confined to the limbs of one side. You have here in all probability a permanent lesion, both irritative and destructive, of the cortical motor area of the right hemisphere. Hughlings Jackson was the first to clearly point out that these cases of partial epilepsy, with hemiplegia or hemiparesis, were usually due to lesions of the convolutions of the brain. A number of cases have been reported by Charcot and his pupils, by Ferrier and others, in which, with symptoms like those presented by this patient, the lesions after death were found to be softening, sclerosis, atrophy, hemorrhage, tumor, tubercle, syphilitic exudation, or injury of the motor zone of the cortex.

When the spinal cord has been examined, usually a band of sclerosis has been discovered occupying the lateral column of the opposite side to the seat of the cerebral disease. This lesion of the cord belongs to the class of secondary degenerations, and is the probable cause of the persistent spasmodic conditions of the extremities.

ETIOLOGY OF DIPHTHERIA.—In discussing the outbreak of diphtheria in London last spring, Dr. T. Morton states that undoubtedly the most common mode by which diphtheria is kept alive in our midst is by direct infection from case to case. It is not probable that the poison is conveyed by fomites, but it is more than likely that very slight and almost unnoticeable cases may be the parents of severe ones. It is certain that milk is a very important factor in causing the disease. Whether it acts directly, *i. e.*, whether the poison is generated by a disease in the cow itself, such as garget, or what the Germans call "perlspeck," or whether the milk is simply a carrier of germs taken in the cow's food, cannot be decided yet. The fact that milk is the infectious agent, however, is sufficiently established.—*Med. Press and Circular.*

PILOCARPINE AS A REMEDY FOR BALDNESS.—Two cases are given by Dr. G. Schmitz, of Berlin, in which pilocarpine caused a new crop of hair to appear on patients previously quite bald. The drug was being given for disease of the eye.

Original Communications.

CEREBRAL COMPLICATIONS OF CHOREA.

By L. PUTZEL, M.D.,

NEW YORK.

APART from the interesting nature of the following cases, I have been led to publish them from the fact that the cerebral complications of chorea have excited so little attention in this country. The histories of these cases also tend to shed some light upon the pathology of the affection, and favor the view that chorea is the result of an abnormal process occurring in the cortical structure of the brain, and not in the basal ganglia, as held by so many English pathologists.

CASE I.—Peter K—, æt. 3½ years, first came under my observation at the Clinic for Nervous Diseases in the Bellevue Out-door Department, on April 22, 1878. The family history is unimportant, there being no tendency to hereditary disease of any kind; neither the parents nor any other member of the family have ever suffered from rheumatism. The patient was always in excellent health until the first week in March, when he suddenly developed considerable fever, followed, in three days, by swelling of the knees and ankles, the joints also becoming exceedingly painful to the touch. This condition lasted three weeks, and was diagnosed as acute articular rheumatism by the physician in attendance at that time. Very shortly after the termination of the rheumatic attack (April 1st), and while the patient was apparently doing very well, he began to suffer from irregular choreiform twitchings in the limbs, which did not, however, attain any considerable severity. A few days later, the child awoke one morning in a condition of great muscular weakness and was unable to articulate, although speech had hitherto been perfect. The paresis gradually grew worse until a week ago (April 15th), since which time it has remained *in statu quo*. The twitchings of the muscles continued up to the present time, but were not of a very marked character.

Present condition (April 22, 1878): The patient is a large, apparently well-nourished child. He has left convergent strabismus, which came on after a slight attack of diarrhœa occurring last July.

Physical examination: The apex-beat of the heart is felt at the nipple; a loud, blowing systolic murmur is present, and is heard most distinctly at the apex; it is also conveyed into the left axillary space, but could not be traced into the scapular region; the second cardiac sound is sharp and distinct.

The patient is unable to swallow solid food, and the mother states that this condition has lasted since the beginning of the paralysis. There is considerable weakness of the upper limbs. The grasp is feeble, and the hands cannot be raised above the shoulders. The lower limbs are even weaker than the upper. There is almost complete paralysis of the anterior muscles of the leg, the feet hanging in the position of talipes equinus, and the toes are only movable to a very slight extent. The patient is barely able to flex the thighs on the abdomen. When placed in a sitting posture, the child immediately topples over to one or the other side, apparently from paralysis of the dorsal muscles. The muscles throughout the entire body feel soft and flabby. It is impossible to get accurate data with regard to sensation on account of the age of the patient.

Reflex action and the electro-muscular reactions are entirely normal. The patient is unable to speak, except to say "yes" or "no" in an indistinct manner. Sleep is very much disturbed. The natural folds of the face are almost completely effaced, and the lower facial muscles appear to be parietic. The eyelids are, however, opened and shut in a normal manner. There is very little power of motion in the tongue, the organ being protruded slowly and only to a slight extent. The choreiform movements are scarcely noticeable, and occur at long intervals. I ordered milk diet, cod-liver oil, and the following prescription:

℞ Tinct. ferri chlorid. ʒ ij.
Potass chlorat. ʒ j.
Syr. simp. ʒ iv.

Sig., ʒ j. t. i. d.

The condition of the child began to mend very rapidly, and a month later the following notes were taken: The patient is able to walk almost as well as ever, and the power of the upper extremities is apparently entirely restored. Slight choreiform movements still continue from time to time; speech is almost perfect. The mother states that during the last two weeks the child has been almost demented, and has not appeared to comprehend the simplest ideas. At times he has apparently had hallucinations of sight; on one occasion, while playing with some toys, he turned around and began to talk with some imaginary playmates, saying "that he was better than they." To-day, however, the patient appears quite bright and intelligent.

June 5th.—The patient is well in every particular, except that the mitral murmur is still distinctly audible, though not so loud as formerly.

The distribution of the paralysis over the entire body, and the coincident mental disturbances, appear to indicate that the morbid process was situated in the cerebral cortex. The rapid recovery would serve to show that the affection was due to some circulatory disturbance (anæmia?), and not to an organic lesion. In my opinion, the existence of endocarditis was merely a coincidence, and cerebral embolism may be excluded by the bilateral character of the paralysis, the rapid recovery, and the probability of a cortical lesion (symptoms of mental derangement).

CASE II.—Fanny M—, æt. 17½ years; family history is entirely negative. She always enjoyed good health until the beginning of the present ailment. Last August the patient caught cold while menstruating, causing a sudden arrest of the menstrual discharge. A week later, choreiform twitchings began upon the right side of the body, and soon increased in violence. After the lapse of three or four weeks, the left side of the body also became involved, but the movements have never been so severe as upon the right side. Towards the end of September the patient had a bad attack of nightmare, during which she started up from bed and wandered about the house in a condition of great fear and consternation. For the next five or six weeks she gave marked indications of insanity. For some time she refused to eat, stating that her food was poisoned and that she was being persecuted by strangers. She evinced hostile feelings toward the members of her family, especially toward her mother, whom she called vile names. At times she failed to recognize her friends and acquaintances, and thought that her female relatives were men dressed in women's clothes. The patient was also vicious and violent, destroying her clothes and various articles of furniture. During this time the choreic movements became extremely violent and continued

even during sleep, so that the patient's limbs had to be tied down in bed in order to prevent her from falling out and doing herself bodily injury. After the affection had reached its height, the choreic manifestations rapidly improved, and the symptoms of insanity began to disappear at the same time. The choreiform movements still persisted, however, to a certain extent, and were present to a moderate degree when the patient first came under my observation. I then prescribed Fowler's solution, beginning with five drops three times a day, and increasing rapidly until twelve-drop doses were taken. Within a week after beginning this plan of treatment, the menses (which had been suppressed since last August) returned, and in less than a month the choreiform movements were no longer noticeable.

In this case the mental aberration was most marked at the height of the chorea, when the movements were so violent that they did not even cease during sleep, and necessitated the application of stout bandages to the patient's trunk and limbs. The prognosis of this form of choreal mania is very good as regards recovery from the insanity. In the majority of cases the mental disturbances disappear as soon as the choreic manifestations have subsided, or within a couple of months thereafter. Cases of maniacal chorea furnish, however, a large contingent of the mortality in chorea, not so much on account of the complication with insanity, but because the choreic movements are so severe that they interfere with sleep and nutrition. This fact furnishes an important guide-post with regard to the treatment of these cases. The faulty nutrition is best met by resorting to rectal alimentation (milk, blood), or to the milk diet per os. The lack of sleep must be combated by the administration of large doses of chloral and bromide of potassium (the quantity must vary with the individual case), and, in some very obstinate cases, chloroform has been successfully employed.

Chorea sometimes simulates insanity, although the mental powers are intact. Thus, choreic patients may appear to be incoherent in their speech, owing to the fact that articulation of speech is interrupted by involuntary movements of the muscles of phonation, giving rise to the involuntary utterance of words or of disjointed sentences foreign to the matter under discussion. This apparent incoherence of ideas, together with the apparent destructive tendencies manifested by the patient on account of his lack of control over the muscles, has led physicians, in several instances, to make a diagnosis of insanity, although the intellect was normal. An English alienist, whose name escapes me, has reported two cases of this nature which had been committed to an insane asylum. The differentiation of such cases from those of choreal mania must depend upon the exercise of the judgment of the physician.

CASE III.—Wm. K.—, *æt.* 8 years; the patient's great grand-aunt was insane; his grandfather died of apoplexy; a grand-uncle was an inebriate; a brother suffers from epilepsy. The mother is nervous and hysterical, but she states that this condition has only developed of late years from the worry and distress consequent upon the ill-health of her children. No member of the family has ever suffered from rheumatism. When three weeks old the patient had pneumonia, and had a number of convulsions during his illness. He also had convulsions at the beginning of an attack of measles from which he suffered during infancy. The patient had two attacks of acute articular rheumatism at the age of three and five years; had another attack, which lasted a week, about eighteen or nineteen

months ago. Two years ago the patient began to have choreiform twitchings in the limbs, which grew worse in the spring, and almost entirely disappeared after the lapse of a year. But even at the present time, considerable muscular twitching becomes apparent if the patient is very much excited. When the patient is calm these movements disappear entirely.

During the course of last summer the patient began to act strangely. He became extremely insubordinate at school, and began to display evidences of very bad temper. Upon one occasion he cut a playmate with a knife on account of a trifling dispute. Last September he began to entertain the delusion that objects around him were placed crooked. When sitting at table, he would carefully smooth out the wrinkles in the tablecloth, was continually moving the dishes in order to straighten them, and stated that the chairs and pictures were crooked. At length he would eat only from a low bench placed upon his knees, on account of his inability to get the table straight. About the same time he began to manifest an uncontrollable aversion toward his mother, to whom he had previously been fondly attached. During the summer the patient was continually finding fault with his clothes, stating at one time that the sleeves were too short, and then again too long. Finally he began to tear off his clothes, and would run around naked, "because his clothes hurt him." The patient also had hallucinations of sight and hearing. Sleep was very much disturbed unless the patient took hydrate of chloral at night. The appetite was very capricious, so that at times he would eat ravenously, and then again would lose all desire for food. The patient would wake up in the morning feeling very tired. I have been unable to obtain a history of any epileptic seizures, either diurnal or nocturnal. The patient has gone to the window several times with the expressed intention of jumping out; he has also threatened to commit suicide by cutting himself with a knife. He also said that he would rather be dead than alive, and remarked to his mother "that she would also prefer death if she felt like him, though he does not suffer from headache." Upon being cross-questioned, he is either unwilling or unable to define the nature of his suffering. His insane condition is not constant, but alternates with intervals in which he appears to be perfectly rational. These intervals are more numerous and longer than they were during last year.

The child's physical condition is excellent, and careful examination fails to reveal the slightest indication of organic disease. The patient is shy, and the expression of his countenance is gloomy and careworn.

I again saw the patient to-day (Aug. 15, 1879) and was informed by his mother that his mental condition has improved considerably during the past month, the child being more sociable in his disposition and manifesting greater affection for his mother than formerly. The treatment consisted in the beginning of Fowler's solution, and hydrate of chloral in ten-grain doses at night. During the past six months, the Fowler's solution was discontinued and the patient received nitrite of amyl, *gtt.* *ijj.* *t. i. d.*, by inhalation. The administration of the latter remedy was usually successful in cutting short an attack of maniacal violence.

The prognosis in this case is very poor, the hereditary tendencies to severe nervous diseases constituting a great obstacle to recovery. This case differs from the preceding one in the fact that the choreic movements were not well developed; hereditary predisposition undoubtedly played an important part in the etiology, and this fact may also account for the con-

tinuance of the mental disturbances. Rheumatism may be disregarded as an etiological factor, both on account of the duration of the insanity, and also because the mental disturbances were not manifested until long after the disappearance of all symptoms of rheumatism.

No. 252 E. 48TH ST.

STATE PROTECTION FOR SYPHILOPHOBISTS.

By HENRY M. LYMAN, M.D.,

PROFESSOR OF PHYSIOLOGY AND OF DISEASES OF THE NERVOUS SYSTEM, RUSH MEDICAL COLLEGE, CHICAGO.

IN spite of the conclusive manner in which this subject has been discussed and decided in accordance with the highest generalizations of science and philosophy, feeble voices may still be heard in remote corners of the land, hoarsely crying for protection by the civil government against the consequences of indiscriminate dalliance with the charms of easy virtue. Such an exhibition of folly might well be left to correct itself were it an isolated fact. But, unfortunately, it is merely an expression, in a particular form, of the immense ignorance which now prevails, and is even fashionable in certain circles, regarding the nature and meaning of disease, and regarding the proper functions of civil authority.

Good government exists solely for the purpose of securing to every one the largest liberty of action consistent with equal liberty for every other citizen. Good government recognizes the individual and individual rights as the highest elements of society; and, consequently, leaves to the individual the responsibility of protecting himself and his private interests in his own way, as long as he does not interfere with the equal rights of his fellows. In this way alone can the highest evolution of human character be secured; in this way strength and self-reliance and self-respect are developed and matured. But every inferior type of government seeks to subordinate the individual, and to make itself supreme. Those forms of government which accomplish this result are bad, because they are so organized as to give to certain individuals an advantage over all other members of the community. Such government is bad, because it unduly restrains the freedom of one portion of society, while it unfairly enlarges the liberties of the remaining fraction. Such a system of government produces, therefore, a one-sided development of all who are subjected to its influence. The most perfect system of government, therefore, is that which bears with the greatest impartiality upon all alike, and which refuses to lend itself to promote the welfare of any person at the expense of the equal welfare of other citizens. A bad system of government, on the contrary, lends itself readily as a means of procuring the special advantage of any enterprising character, or class, who may succeed in capturing the machinery by which it is administered. Constituting, as it does, an engine of tremendous power, the history of the world consists principally of a record of the manner in which energetic people have wielded the power of government for their own benefit. Unscrupulous people who thus regard the political machinery of society, are always ready to enlarge the sphere of government. Every additional extension of this sphere means a greater limitation of individual liberty and individual evolution. Every such extension adds to the importance of the official administrators and their friends—consequently every official class naturally seeks to help

itself by promoting the increase of official functions. At the opposite end of the social scale will always be discovered a class of indolent or enfeebled persons who are ready to fix themselves as parasites upon any social organization that seems to possess energy sufficient to sustain their weight. A government which is not maintained for the simple purpose of securing equal liberty for all, offers to such a class the greatest chances for private advantage; consequently, this inferior form of government will always be preferred by the governing class, and by the indolent and selfish substratum of society. With all such people *protection by government* is the uppermost idea. But by such protection they do not mean equal rights and equal liberty for all. The officials long to enhance their own importance by intruding their protection where it is not needed; the vagabonds insist upon protection, at the expense of honest people, against the consequences of the unbridled indulgence of their own vicious propensities.

The dangerous classes just mentioned often receive noisy reinforcement by a third class—the pseudo-philanthropists—commonly called sentimentalists, because they habitually surrender themselves to the control of their untutored feelings, instead of following the guidance of enlightened reason. These people can think of nothing but the immediate relief of suffering in what seems to them the shortest possible way. As the civil government presents to their teardimmed eyes the most imposing form of visible energy, they straightway fill society with a shrill cry for government aid against intemperance, and poverty, and syphilis, and scarlet-fever, and every other evil, without once stopping to consider whether individual citizens cannot just as well undertake their own protection against such dangers. Here, then, we find the explanation of the demand for state protection which forms a characteristic so discreditable to our present grade of social evolution. The manufacturing chemist insists that government shall “protect” him, at the expense of the nation, against everybody who can sell quinine cheaper than he can. The “statesman” wishes to be protected, in like manner at the expense of the nation, against the fever which his own social habits invite. The tramp boldly demands protection of the same sort, that he may enjoy a life of leisure—*otium cum dignitate*. The “gentleman” who picks his teeth in front of a fashionable hotel, thinks very meanly of a government which will not relieve him of all necessity for caution in the indulgence of his appetites—and all at the expense of honest citizens who have no time for anything but hard work and the practice of rigid virtue. A mere statement of the purposes of such legislation is sufficient to show its inequity and injustice.

It has been proposed to avoid this objection by taxing prostitutes in a sum sufficient to defray the expense of protecting their customers against them. But, to say nothing of the fact that such taxes have never been known to equal the cost of the increased machinery of government, we still meet the same unequal distribution of burdens which always accompanies protective legislation. The weight of taxation, as of shame, is thrown entirely upon the women themselves by this method, which thus becomes an additional refinement of selfishness; and society is expected to acquiesce in this prostitution of its own political machinery for the benefit of its most vicious and heartless members—while sentimentalists tell us that we must not object to any such arrangement, for fear of being eaten up by syphilis! Brave men are not afraid of any such risk.

The supreme selfishness to which allusion has just now been made indicates the existence of a moral side to this question. In fact, since man is a moral being, no adequate discussion of this subject is possible without a full consideration of its moral relations. But, since medical periodicals are not published for the sake of diffusing the principles of morality or the reverse, the proper place for such a discussion would be in some journal devoted to social science. I will, therefore, pass over this most important topic—though nothing daunted by the sneers with which men of undeveloped moral sensibility seek to cast obloquy upon all who undertake to investigate every side of whatever subject they may consider. The narrow way of looking at everything, to which our sentimental friends are so partial, is probably owing, however, to a defective visual capacity rather than to any actual moral obliquity; but it is a very serious impediment to scientific investigation, even when the field of research is restricted to the domain of the physical science. Consequently we find our philanthropic sanitary legislators continually falling into the error of attempting to deal with men and women as if they were so many cattle, instead of free and intelligent beings. Hence the universal failure of all such legislation when it cannot be enforced with powder and ball. Hence the great mistake of supposing that sanitary measures, which may produce good results among soldiers, will benefit civilians.

An army is a machine which exists for the single object of war. A soldier must be healthy and ready to fight—he need not, had better not, be too scrupulous about morals. Consequently, so far as the indulgence of his appetites is concerned, the only question for consideration is the prevention of disease as a result of indulgence. Anything which will protect him from disease is good enough, for he is not to be treated as a moral being, but as a combatant. But civilians are not so to be regarded; they are men and women, and they have rights—social and moral—which no one may safely ignore. For this cause, the alleged success of certain methods of dealing with prostitution among soldiers constitutes no reason whatever for the conclusion that the same methods will benefit civil society. The conditions are totally different, consequently the results must be as widely different.

In addition to these arguments, and to many others which may be drawn from political science and from moral philosophy, may be urged the argument of experience. In every community where the experiment has been tried, it has been found that the registration and inspection of prostitutes fails to secure absolute protection for debauchees. Women who pass the official examination may still carry within themselves the seeds of disease, and may infect a paramour whose caution has been lulled to sleep by an official certificate. It has also been found utterly impossible to maintain a system of inspection without the establishment of a loathsome brood of spies and informers, whose influence upon society is of the worst possible description.

Dismissing for the present all further notice of considerations derived from the higher sciences, we find that the entire proposal for state protection of syphilophobists is utterly opposed to the wholesome laws of nature which, if unobstructed by meddling interference, will surely accomplish the highest physical good of mankind. As Herbert Spencer has wisely remarked, disease and pain are simply the admonitory result of being out of harmony with one's surroundings. Without such warning it would be impossible for a conscious being ever to learn the fact of such mal-adjustment, and the evolution of the human race

would be indefinitely retarded. But, stimulated by such monitions, through the aid of natural selection, two classes of human beings are growing into prominence. The first, by sobriety and by self-control, puts itself beyond the reach of venereal disease; the second, by constant transgression, will become at length thoroughly adjusted to the brutal condition, and, ceasing to be out of harmony with its surroundings, will practice promiscuous fornication with an immunity equal to that which attends the similar performances of a dog or a goat. The great restriction and progressive amelioration of syphilis which has taken place within the period of modern history proves that this strictly scientific expectation is not so very far from accomplishment at the present time. But, if these wholesome natural processes are to be rudely hindered by the three dangerous classes of the community above mentioned, the process of the adjustment of mankind to its surroundings will be greatly delayed, and the sum total of human anguish will be greatly increased. State protection for the vicious is, therefore, the most thoroughly unscientific thing that can be proposed, as every one who has comprehended the theory of evolution must necessarily perceive. But, since sentimental people are sentimentalists by reason of their incapacity for certain kinds of knowledge, every effort thus to address them with scientific arguments must be as fruitless as would be the attempt to discuss politics with a pig. One must have a capacity for sight if one would see. To their own devices, therefore, must we abandon all such people.

CLASS-ROOM LESSONS ON CHANCROID,

GIVEN AT THE COLLEGE OF PHYSICIANS AND SURGEONS IN THE CITY OF NEW YORK.

By FESSENDEN N. OTIS, M.D.,

CLINICAL PROFESSOR OF GENITO-URINARY DISEASES,

[FOR THE MEDICAL RECORD.]

I.

CHANCROID — ITS CHARACTERISTICS — ITS HISTORY — ITS DIAGNOSIS.

GENTLEMEN:—To-day we will begin the study of chancroid, and the lesson will be restricted to general remarks regarding its characteristics, its history, and perhaps its diagnosis.

Chancre is an acute, contagious ulceration, recognized as resulting from venereal contact. It is a purely local disease, possessing characteristics which entitle it to be considered, *par excellence*, the highest type of acute ulcerative action. In the great majority of cases it is the result of inoculation of the purulent secretion of an already existing ulcer of a similar character. Applied to sound integument or mucous membrane, it is capable, under favoring circumstances, of effecting a solution of continuity of the part, and of communicating to it at once its destructive and contagious properties. More commonly and readily it is established upon an abrasion of the skin or mucous membrane produced *in coitu*. On application of the purulent secretion of *chancre* to an abrasion, either on the person already affected or on one previously free from the disease, congestion, inflammation, suppuration, rapid destruction of tissue follow in quick succession. The ulcer thus formed presents all the characteristics of rapid destructive action; it is sharply cut, with ragged edges and pultaceous floor, and secretes pus freely. Chiefly characterized by its

contagious property, the chancroid is seldom single, several distinct lesions usually presenting at the same time. Occurring under circumstances of good general health, cleanliness, and temperate living, its progress is usually self-limited; gradually increasing from two to five weeks, it acquires a diameter of from three to six lines; the loss of tissue is then slowly restored, and a scar like that of an ordinary burn is left. From first to last its secretion is inoculable, and the sore is capable of being reproduced upon the person bearing it. When reproduced by artificial inoculation it loses its contagious power in each successive inoculation until the secretion from it is no longer inoculable. It will thus be seen that the tendency of the disease, under favoring conditions, is always toward recovery. When acquired under unfavorable conditions, however, such as a depraved constitution, irregular life, filth, and alcoholic excess, the chancroid assumes its most vicious type. Characterized now by a high grade of inflammatory action and an increased destructiveness, it not unfrequently takes a peculiar action which is termed phagedenic, through which, in a few days, or even hours, important loss of tissue ensues, not rarely resulting in irretrievable mutilation, and possibly in loss of life. In other rarer instances, the *chancroid* takes on a sluggish but persistent form known as the *serpiginous*, with a gradual irregular loss of tissue, involving the integument only, but continuing often for years despite every means and mode of treatment. The extension of the *chancroid*, usually by continuous tissue, not unfrequently takes place through the entrance of the contagious secretion into a lymphatic vessel (opened by chancroidal ulceration), and its passage along that vessel to the adjacent lymphatic gland. This accident may occur at any period during the continuance of the chancroid. The gland in this manner affected (usually in the groin, and known as the chancroidal bubo), becomes tender and swollen. Evidences that the peculiar destructive chancroidal action is going on within the substance of the gland become daily more distinct, until in a few days an abscess is formed. On the discharge of the purulent contents of this abscess, they are found to possess the peculiar properties of pus from the original ulcer, and the open bubonic abscess takes on the appearances and other characteristics of the typical chancroid.

The *venereal ulcer*, or *chancroid*, in its early stages, is promptly amenable to judicious remedial measures. The application of any caustic, of sufficient power to destroy completely all the tissue which has been implicated in the diseased action, suffices to change the contagious venereal ulcer to a simple sore, when it goes on to recovery without other treatment than such simple sores require. The conditions which determine the severer forms of the chancroid are recognized as already stated. It is also found that the particular lesion which may present partakes in great degree of the activity, greater or less, which characterized the lesion from which it was derived, so that every grade, from the simple excoriation to the sharply defined and most active ulcer, may be met. Hence, all do not require the prompt and energetic course necessary to arrest and cure the typical chancroid. In the milder varieties, the judicious application of carbolic acid, iodoform, sulphate of iron, and other, even simpler antiseptic, sedative, and astringent agents, may suffice to bring about an arrest and cure. In the lightest forms it is often difficult to distinguish from non-venereal pustules which result from acrid sebaceous secretions, or from connection with a female suffering from an acute form of simple leucorrhœa.

In regard to its history, the chancroid is conceded to be of ancient origin, even to antedate the advent of *syphilis*. It has various synonyms—viz: "pseudo-syphilis," "soft chancre," "non-infecting chancre," "chancroid," etc. By the latter term, *chancroid*, it is almost universally known at the present day. It was distinctly recognized and described by the ancients as a disease known from the earliest times. Notwithstanding this, shortly after the recognized appearance of syphilis in Europe in 1492, it became confounded with that disease. Its purely local character was obscured, and it was subjected to constitutional treatment as a form of syphilis. Its chief characteristics, however, always most marked, were never quite lost sight of. Evincing its destructive property *at once* on inoculation of its secretion upon healthy tissue, and commonly associated with inflammatory enlargement and suppuration of contiguous lymphatic glands, it was thus directly opposed to the sluggish course of the syphilitic local affection and its non-suppurating glandular concomitants. Yet it was so often found associated with and followed by the constitutional manifestations of syphilis that its distinctive significance was doubted; and when, after a time, the well-known acute venereal ulcer was occasionally observed to exchange its soft edge and base for the indurated tissue known to characterize the early syphilitic lesion, the fallacious theory of *post hoc ergo propter hoc* prevailed, and thus the confusion of the two distinct diseases became complete. From this time *all* the contagious venereal diseases, gonorrhœa, chancroid, and syphilis, were accepted as practically identical, requiring the same constitutional treatment. It was found, however, after the habitual mercurialization of persons afflicted with soft sores or with gonorrhœa, for more than two hundred years, that constitutional syphilis did not necessarily follow the occurrence of the soft ulcer nor of a gonorrhœa, even when no treatment was resorted to, while the ulcer with indurated base and edge was invariably succeeded by the general manifestations of syphilis. John Hunter, in 1786, was the first to recognize publicly the value of the induration characteristic of the venereal sore which was followed by constitutional syphilis, thus making the first positive step toward identifying and restoring to the different venereal disorders their distinctive individuality. Hunter, however, misled by an experiment upon his own person, taught that while the local manifestations of the venereal diseases were different, their source of origin was identical, and that the peculiar form and nature which they assumed in any given case was dependent upon some peculiar condition or idiosyncrasy of the affected individual. In 1798 Benjamin Bell of London claimed a simple origin for gonorrhœa, and in 1830 M. Ricord of Paris, after a series of observations and elaborate experiments in inoculating the purulent fluid of gonorrhœas and the secretions of the soft and hard venereal lesions, demonstrated the purely simple, non-specific nature of gonorrhœa, thus completely and forever eliminating it from among the manifestations of syphilis. Ricord, however, notwithstanding his numerous and carefully observed inoculations, and while distinctly recognizing the local and ultimate differences between the hard, or Hunterian chancre, and the soft sore, or chancroid, yet accepted and taught Hunter's view, that the difference between them was not one of origin, but of personal condition or idiosyncrasy. It was reserved for M. Bassereau of Paris (a pupil of M. Ricord), in 1852, to demonstrate the fact that in the disease then known as syphilis, comprising the soft local venereal ulcer and the indurated infect-

ing venereal sore, with its consequences, two separate diseases existed. Upon the confrontation (*i. e.*, personal comparison) of a very large number of persons affected by venereal disease, with those from whom their disease had been acquired, Bassereau found that in every person presenting a venereal ulcer, accompanied by well-pronounced evidence of constitutional syphilis, the person from whom the disease had been acquired was also, or had recently been, the subject of ulcers which were followed by constitutional syphilis, and that in no case was syphilis ascertained to originate from a person bearing the soft venereal ulcer alone. Similar observations by confrontation were made by Messrs. Dron, Clerc, Diday, Rollet, and Fournier in 1856, and in 1857 by Messrs. Fournier and Cuby, under the supervision of M. Ricord, with the result of proving that in all cases of chaneroid the type of ulcer remained unchanged in passing from one individual to another. Nevertheless, M. Clerc, while accepting and confirming the observations above alluded to, claimed to have produced the typical chaneroid by inoculation of the secretion of an infecting (syphilitic) chanere upon a person previously the subject of syphilis, and thus to have demonstrated that the chaneroid was the product of the inoculation of the syphilitic virus upon persons then or previously affected with syphilis. Clerc also claimed that while, as a rule, the chaneroid thus originated usually transmitted only chaneroid, yet on being inoculated upon a healthy person it was capable of reverting to its original type, and hence of communicating syphilis; thus asserting the unity of origin of the two diseases; and those holding this view were known as *unicists*. Rollet and others held, on the contrary, that not only were chaneroid and chanere (the initial lesion of syphilis) separate and distinct diseases, but that they owed their origin to separate and distinct poisons; and thus the school of so-called *dualists* was initiated. The position of M. Clerc was supported by the observations of Henry Lee of London, the late Prof. Boeck of Christiania, Melchior Robert, and others, who succeeded in producing the typical chaneroid upon persons syphilitic and non-syphilitic by inoculations of pus from an irritated syphilitic chanere. It was required that the degree of irritation in all cases should be sufficient to induce a free *purulent* secretion. Sores produced in this manner were inoculated in successive generations upon persons quite free from syphilitic taint, and behaved in all respects like the ordinary venereal chaneroid. It was, however, found that when the superinduced irritation subsided, and the secretion was no longer purulent, it was no longer auto-inoculable; and hence it became evident that the property of inoculability was consequent upon a peculiar action resulting from the persistent irritation of an already diseased surface. The fact that the chaneroid could be established upon persons entirely free from syphilitic taint, and not be followed by syphilis, demonstrated that its existence was not necessarily dependent upon the syphilitic principle. Experiments were then made by Pick, Bidencap, Koelner, Boeck, and others, to ascertain the effect of inoculations of pus from simple lesions on persons free from syphilitic taint. The result showed that affections in non-syphilitic persons which are of slight virulence, the secretions of which are not inoculable, can be made to produce an inoculable secretion by the application of an irritant. Kaposi states that in his experiments the pus taken from acne, and from scabies in non-syphilitic individuals, has produced pustules, the pus from which was inoculable in generations on the bearer as well as on other non-syphilitic persons. In 1866 Dr.

Edward Wigglesworth, Jr., of Boston (reported by Dr. Bumstead in his paper *On the Unity and Duality of Venereal Sores*, read before the Centennial Medical Congress of Philadelphia), while studying under Prof. Zeissl of Vienna, and being entirely free from any suspicion of venereal taint, but in somewhat impaired general health, inoculated his own arm with pus taken from a simple pustule of acne. This produced a similar pustule at each of the three points of inoculation. Pus from these being again inoculated, a third generation was established. Nine distinct sores, the result of the inoculations, were present at the same time, and, pursuing a similar course, finally healed, leaving as many distinct cicatrices, indicative of loss of tissue through the process of ulceration. This experiment during its progress was under the personal observation of Prof. Zeissl, and was repeatedly exhibited to his class as demonstrating the contagious and destructive properties of non-specific pus under certain circumstances unconnected with syphilis or with any venereal influence. Observations (personal) have shown that the muco-purulent secretion from non-specific nasal catarrh will sometimes produce excoriations of sound cuticle, and that contact with secretions from non-specific leucorrhoeas will sometimes promptly cause pustular eruptions (*herpes*) of the preputial mucous membrane of the male; and these more or less rapid in development and progress according to the degree of activity of the inoculating secretion (in some instances so simple that they are scarcely more than sero-purulent vesicles, and in other cases observed so vicious that in appearance they do not differ at all from the typical chaneroid), the secretion being also *auto-inoculable*, as proven by the occasional occurrence of similar lesions upon opposing surfaces.

Mr. John Morgan, of Dublin, in his work on venereal diseases (1873), cites numerous instances in which he has observed the typical chaneroid to result from inoculation of the muco-purulent secretions of leucorrhoeas in syphilitic women, upon other women, also subjects of syphilis. Vidal cites a case where pus taken from a pustule of simple cethyma, in a patient suffering from typhoid fever, was promptly inoculable on the patient, but failed when inoculated upon a healthy person. It is therefore shown that the quality of pus is variable, according to the circumstances under which it is produced and the condition of the person upon whom it may be inoculated. That a low condition of the general system from any cause predisposes the healthy tissues to take on ulcerative action and to elevate the accompanying purulent secretion to a point of contagiousness. Lesions, especially of mucous membrane of the human genital apparatus of both male and female, are common under the circumstances peculiar to the venereal act. Inflammations of mucous membrane in the same locality are frequent, and characterized by muco-purulent secretions, often profuse and acrid; and this, too, when the subjects of them are in good general health and living under the most favorable hygienic conditions. When, therefore, it comes to be considered that the most frequent habitat of the chaneroid is in localities where venereal excess and every kind of debauchery abound; when to this are often added the potent elements of syphilis and serofula, hereditary and acquired, filth, and irregular living; and when (as has been shown by Fournier* and others) chaneroid is found by far the most frequent in proportion to syphilis among the de-

* Fournier noted in his private practice, 82 simple, 252 infecting; in Hospital du Midi, of 341 chaneres, 215 were simple; and the report of service in the same hospital, where 10,000 cases of venereal sores were treated, 8,045 were and to have been simple chaneroids.

based and dissolute, the conclusion is inevitable that chancroid is, and of necessity must be, a self-engendered disease, possessing no specific virus, but acquiring its power for destruction and contagion through the stimulation and vitiation of benign natural processes.

The venereal ulcer or chancroid acquires its chief importance from its liability to be mistaken for, and treated as, the initial lesion of syphilis. The distinction between the two lesions at the outset is often impossible. The active characteristic of the chancroid is recognized as a necrosis—that of the syphilitic lesion one of growth or proliferation. The surface of a sore, then, may be the field of chancroidal action, while the living tissue beneath may be at the same time a centre of proliferation of syphilitic disease-germs, which are constantly gaining access to the general circulation through the contiguous lymphatic vessels. These germs may be originally deposited upon a simple abrasion or one already the seat of chancroidal action, or may possibly be subsequently inoculated through the breach of tissue made by the chancroid. If the former, the imposition of the secretion of a chancroid upon the same point, if the disease germs have been freshly deposited, might cause their destruction, and thus leave only the chancroidal element; but once the syphilitic principle has extended below the surface and has entered a lymphatic vessel it has gone beyond the sphere of action of the chancroid. The only method of determining whether a given chancroid or other lesion, occurring after a suspicious venereal contact, is or is not to be followed by constitutional syphilis, is to reserve a final decision for a full month subsequent to the exposure. This course should be pursued even though during the interval the suspected lesion, possessing all the characteristics of the typical chancroid, should have fully healed. If during or after the month no hardening of the tissues composing the edge and base of the sore, nor, if healed, of the cicatrix, nor any enlargement of the adjacent lymphatic glands, can be discovered, then, and not until then, can the patient be assured that he has had an uncomplicated chancroid, and that no syphilis will follow. Those milder forms of ulcerative action which are just within the line of distinction between the simple so-called herpes and the chancroid are the most frequent to exhibit subsequent evidences of syphilitic infection. By reason of their inactivity they are less likely to destroy any of the germs of syphilis which may come in contact with their surface.

The frequent association of chancroid with syphilis will never lead to mistaken identity if it is constantly borne in mind that syphilis is always, in all its manifestations, a process of growth, of proliferation. The most scientific and critical examination of the products of syphilis, from the *initial lesion* to the *gummy tumor*, has never been able to detect any abnormal material—nothing but excessive accumulations of tissue-building cells. Chancroid, on the other hand, from its inception to its cicatrization, is a process of necrosis—literally, *death* of tissue. So that *syphilis* and *chancroid* are always and only in relation to each other as *life* to *death*—each the highest type of its own peculiar action.

(To be continued.)

Progress of Medical Science.

TANNATE OF PELLETTIERINE AS A TÆNIAFUGE.—The active principle of the bark of the punica granatum, discovered by M. Tauret, and described by him under the name of *pelletierine*, has been used with success as a remedy for tænia. It is given in the form of the tannate, in the dose of 50 centigrammes, followed in two hours by 30 grammes of castor oil. Dr. Laudrieu describes its action as follows:

In the two cases observed neither colic nor headache were occasioned. In the first the patient had been prepared by dieting, and a single dose sufficed to expel the tænia entire. In the second one dose did not suffice, it is true, but the patient was not weakened by the treatment. The patients did not exhibit that repugnance so constantly shown to the administration of koussou or the pomegranate bark. In a third case the administration of a dose of the chlorhydrate of pelletierine brought away 15 metres of worm, the only phenomena observed being diplopia and a slight tendency to syncope, both of which quickly passed off.

The pulse and temperature were not influenced by this medicine; nor were the kidneys in any way affected. The medicine seemed to have an elective and toxic action, operating solely on the tænia.—*Journal de Médecine de Bordeaux*, June 28, 1879.

ON THE STRUCTURE OF BRUNNER'S GLANDS.—Prof. Renault, of Lyons, has made a careful microscopic study of the Brunner's glands of the human duodenum, and states that they are not, as generally believed, conglomerate glands like the salivary, but resemble rather the mucous glands of the œsophagus and bronchi. The specimens of intestine examined were removed from the body of a decapitated felon thirty minutes after execution, and while the heart was still kept beating by mechanical irritation. He found the glands in question arranged in two distinct layers, one being situated in the *muscularis mucosa*, and hence in the deeper parts of the intestinal mucous membrane, and the other in the loose submucous connective tissue, in direct contact externally with the muscular coat of the gut. In structure each gland consists of a series of multifidous culs-de-sac, the lateral diverticula situated on a collecting tube opening directly into it without any contraction in diameter. The connective tissue framework of the glandular tube is disposed in the form of a spur at the junction of the secondary with the primary culs-de-sac. Prof. Renault compares these culs-de-sac to the ramifying fingers of a glove, while the salivary glands, with which Brunner's glands have hitherto been considered analogous in structure, are most correctly compared to a bunch of grapes. In the salivary glands each acinus empties its secretion into an intralobular duct, which unites with others to form interlobular and interlobar ducts, the epithelium of each anatomical subdivision of the gland having its own peculiar characters. In Brunner's glands, on the contrary, each lobule is formed of from fifteen to twenty culs-de-sac opening one into another, without anything resembling intra- and inter-lobular ducts, and the epithelium presents the same characters in all parts of the gland. It is composed of clear prismatic cells, with a flattened nucleus crowded toward the base; the cells are longer than they are broad, are completely filled with mucus, and are entirely analogous to the cells of the muciparous glands of the œsoph-

RED CINCHONA as a remedy for habitual drunkenness is receiving considerable indorsement from English physicians. It is by no means considered a specific, but it is a useful adjuvant to beef-tea and good resolutions.

agus, bronchi, and pylorus. The base of each cellule, however, is prolonged into a sort of minute cue, which is insinuated under the neighboring cell. The connective tissue forming the membrane of the gland presents minute projections, which embrace the bases of the epithelial cells. Prof. Renault has not succeeded in demonstrating a subepithelial endothelium; on the contrary, the fixed cells of the connective tissue envelope are separated from the epithelial layer by a delicate transparent border, which remains untinged and contains no nuclei. The epithelium of the collecting tubes differs from that of the culs-de-sac only in the cells being a little flattened. These tubes open either at the bottom of a fold of mucous membrane or into a follicle of Lieberkuhn.

The glands of the external group form more voluminous masses, which are divided off into lobules and lobes, but in their minute structure they are identical with the glands of the internal group. The glands of the two groups often communicate through gaps in the muscularis mucosae. Prof. Renault states it as his opinion that Brunner's glands are destined for the secretion of a peculiar mucus, but not of any ferment. In support of this opinion, he adduces the absence of the zone of granular cells characteristic of glands that furnish a mixed secretion of mucus and ferment. He claims that these glands form, with the true mucous glands of the œsophagus and bronchi, which present the same fundamental characters, a natural, distinct, anatomical group, totally distinct from the group of conglomerate glands proper, the type of which is the parotid or submaxillary.—*Le Progrès Médical*, June 7, 1879.

A CASE OF LONG-CONTINUED PRIAPISM ACCOMPANYING LEUKÆMIA.—Dr. Salzer, of Worms, reports the case of a man, 46 years of age, who suffered for seven weeks from persistent priapism. He had previously suffered from intermittent fever, but was at this time in apparent good health. One morning he was awakened by an intensely painful erection of the penis, that proved utterly rebellious to treatment. Leeches, warm fomentations, chloral hydrate, and even chloroform narcosis were tried in turn, but all without success. The urine was passed with difficulty, usually in short jets, and most readily in the knee-elbow position. Physical examination revealed only marked enlargement of the spleen. Finally, after the penis had been kept for three weeks constantly enveloped in strongly camphorated narcotic poultices, opium and camphor being administered internally at the same time, the priapism gradually disappeared, having persisted fully seven weeks. During the week preceding this attack, the patient had had two attacks of priapism, one of which lasted only a few hours, and the other twenty-four hours. After the appearance of the priapism the patient rapidly lost strength and acquired a cachectic appearance, and the spleen progressively increased in size. Two months after the priapism disappeared there was complete loss of sexual power, and the patient died about eight months afterward. The blood was not examined microscopically, and an autopsy was not permitted.

Dr. Salzer collates from medical literature eight cases of priapism occurring in connection with leukæmia. Various theories have been brought forward to account for the priapism in these cases. Kremme ascribed it to extravasation of blood into the corpora cavernosa, and Longuet to impeded circulation in the smaller vessels and the formation of thrombi, resulting from the altered condition of the blood, while Neidhart thought that irritation of the nerves might

possibly be the exciting cause. Dr. Salzer thinks that the rapid disappearance of the priapism in the two first attacks in the above case argues against the occurrence of an extravasation of blood. He believes that both the temporary and the persistent attacks of priapism were due to irritation of the nervi erigentes. It is well known that priapism may be produced both by peripheral and by central irritation of these nerves. As examples of the former, he adduces the erections accompanying inflammation of the urethra or of the neck of the bladder, swelling of the prostate, etc.; and, as examples of the latter, the erections of insane persons, or that follow injuries of the spinal cord. The priapism of leukæmia, he claims, differs from these varieties chiefly in its longer duration, and hence for its development some special cause must be sought. This may possibly be found either in the presence of anatomical changes in the nervi erigentes, or in pressure on them, ex. gr., by swollen lumbar glands.—*Med.-Chir. Rundschau*, June, 1879.

TREATMENT OF URTICARIA BY ATROPINE.—In 1876 Dr. Fraenkel recommended the internal administration of atropine in the treatment of severe forms of urticaria. Dr. Schwimmer now reports three cases of this affection, which, after proving rebellious to all the usual methods of treatment, were rapidly cured by atropine. These three cases, however, show that the atropine treatment does not prevent relapses. Dr. Schwimmer believes that urticaria is simply an angioneurosis, and ascribes the efficacy of the drug to its action on the sympathetic system.—*Lyon Medical*, July 13, 1879.

SALICYLIC ACID IN THE TREATMENT OF LUPUS.—Dr. Ameglio reports a case of ulcerative lupus of the face, of five years' duration, in which he employed salicylic acid locally, after all the usual applications had proved ineffective. The ulcerating surface was painted three times a day with a solution of six parts salicylic acid in twenty parts glycerine. After a few days the readily bleeding vegetations withered, and the floor of the ulcer took on a healthy appearance; at the end of the month cicatrization was completed. The patient at the same time took arsenic internally.—*Gazette degli Ospedali*, and *Med.-Chir. Rundschau*, June, 1879.

USE OF Pilocarpinum Mercuricum IN CHILDREN'S DISEASES.—Prof. Weiss has studied the effects of pilocarpine in fourteen children suffering from nephritis, with general dropsy, following scarlatina. In four of the cases there existed, also, extensive bronchitis, in two diphtheria, and in one pneumonia of the left lung. The medicine was administered hypodermically, four or five drops of ether being added where collapse was feared. The following are the author's conclusions: 1. Pilocarpine has proved to be a very successful remedy for children suffering from nephritis and scarlatina. 2. In giving it to children, care should be taken to begin at first with small doses, which may later on be gradually increased. 3. If the little patients are very weak and likely to collapse after the injection, a few drops of ether should be added to the pilocarpine solution. 4. The drug produces a very copious and lasting secretion of sweat, such as no other drug has ever been known to call forth. It acts quickly. 5. In cases of bronchitis, complicated by dropsy, which often produces dyspnoea in children, the affection of the bronchi vanishes very soon after the remedy has been administered.—*London Medical Record*, May 15, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 6, 1879.

THE BRITISH MEDICAL ASSOCIATION.

WE were favored with a report of the proceedings of the British Medical Association at the earliest date possible, and gave it to our readers in advance of the complete report as it appears in *The British Medical Journal*, the journal of the Association. It is gratifying to hear that the late meeting held in the city of Cork, Ireland, has left behind it so many pleasurable recollections. Nothing was left undone which could be regarded as likely to add to the convenience and the happiness of the guests, or to facilitate the business of the Sections.

One feature in the general management of the Association, during the annual meeting just held, is worthy of special mention, and we hope it may find its exact counterpart in the next Annual Meeting of the American Medical Association to be held in this city. It is this: the whole of the numerous meetings, committees, and sections of the meeting, were provided for under one roof. None but those who have attended the meetings of such Associations can fully appreciate how much such a convenience contributes to the actual scientific work done by their members.

We are pleased to learn of the financial prosperity of this Association, and we are also happy in receiving the information that its prosperity is largely due to the aid afforded by a well-managed medical journal, which circulates weekly nine thousand copies. The Honorary Treasurer made the satisfactory announcement that the excess of assets over liabilities at the close of the year—embracing income from all sources—amounted to upwards of six thousand pounds.

We have reason also for good feeling in the fact that the Association, through its journal, acknowledges that the working value of the meeting and the distinction of the gathering was increased by a considerable number of scientific guests from "other lands," who brought with them important contributions of

new knowledge, and a weight of reputation and international character. Among the distinguished visitors from this country, whose names were not mentioned in our report, we notice Drs. E. G. Loring and C. E. Agnew, of New York, and Dr. Wm. H. Byford, of Chicago, who gave to the Association valuable accessions of scientific work.

The meeting itself is a testimony to the united spirit which the whole profession, both in the new and in the old world, begins to feel, and we hope that the smoking flax will not be quenched.

The American Medical Association holds its next Annual Meeting in the city of New York, a point easy of access from all parts of the world, and we believe we speak the sentiment of the profession of this city and of this country when we say, we hope that to American physicians and surgeons may be accorded the privilege of greeting distinguished visitors from the old world, more numerous than those from the new world who have just been made the recipients of the hospitalities of the British Medical Association.

But we wish to acquaint our readers a little more extensively than has been done in our report with the scientific work of the Association. A sketch of the address in Surgery by Mr. Savory has already been given. It was largely devoted to the question of antiseptic surgery, and as that is the topic of the day, the remarks of one who has had immense experience in one of the largest hospitals in Europe are worthy of a more extended reference than they have received.

It has been the great theme of surgery to prevent blood-poisoning after wounds and operations, and, says Mr. Savory, "a splendid struggle now goes on through England, Europe, and the civilized world to reduce the mortality from this cause after operations to the lowest possible terms." The chief glory of surgery during the past twenty years has been the great advance which has been made in all its processes, and now the question arises, How has this result been secured? Mr. Callender, one of England's able surgeons, during his last visit to this country, spoke to our medical students and to our surgeons of the details of the dressing of wounds and the management of the patient after undergoing a surgical operation, so that the least possible shock should be given to the system, and the least possible disturbance to the processes of repair. We were all favorably impressed with the exceeding simplicity and yet great value of his surgical advice. He depended upon careful attention to the details, prior and subsequent to the operation, rather than a formidable array of steam-boilers, glistening instruments, and elaborate apparatus to give him the best possible results. Mr. Savory, in answering the same question, also says that the advance has been secured by "increased care and attention to all the details of the dressing of the wound; the state of the patient's health, the selection of the operative procedure, the surroundings of the patient,

and especially by a comprehensive study of the difficulties which each surgical case presents." While Mr. Savory does not reject Mr. Lister's plan, he assumes what seems to us to be a very sensible position, namely, that the attention of surgeons has been too exclusively fixed upon what is called "antiseptic surgery," and that the importance which belongs to other matters has been overlooked.

We have often been impressed with the question, and it seems that the attention of others has been turned in the same direction, Why do open wounds heal so kindly, if it be true that the atmosphere is laden with deadly germs which are ready at all times to enter and develop blood-poisoning? The truth is, so far as we have been able to ascertain, that no physical proof of the germ theory has been given, and it is this fact, perhaps, which has led the strongest advocates of the Lister plan to persistently avoid the challenge to show by actual comparison how far their results are really superior to those obtained by surgeons who do not adopt the method of treatment.

"The foul and ugly mists of vapors that did seem to strangle him" may with propriety be reduced by a "twenty per cent. of carbolic," and "upon my life, it will do well," but as one of our able contemporaries puts it, we do not believe that bigotry or stupidity is shown in requiring experimental proof of the superiority of the practice before admitting the exclusive claims of the antiseptic method.

To the knotty points in this question Mr. Savory turns his attention, and discusses them with the ability of a master in the art. He does not evade the following question: Are there classes of cases which can be treated successfully by Lister's method, and not by simple treatment? but gives us this answer: "I take leave to doubt whether these assertions are borne out by facts. In my humble opinion, operations are sometimes performed, both with this method and otherwise, which in any case had better be left undone; but I believe that patients have escaped with life after operation as full of risk to it, with other methods as with this. But this sort of statement, because it admits of no direct refutation, is never wanting in favor of any novelty. Has any new plan of treatment ever been proposed unsupported by abundant illustrations of its excellence?"

It might seem at first that Mr. Savory's address is an attack on Listerism; but it cannot, in justice to its author, be so construed, because he pursues an independent line of argument to show that, in hospital surgery, the best results have been obtained by the simplest means. It may be said, and with a certain degree of truthfulness, that operations are now undertaken, such as opening into the knee-joint, into the abdominal cavity, and are safely performed under complete antiseptic precautions, that, previous to the introduction of the system, were approached with very great timidity. Yet it is equally true that some sur-

geons, especially in this country, habitually practised opening large joints—the safety, as they claimed, depending upon the manner of performing the operation—many years antedating the birth of Listerism. However, if there is no principle in the plan, and it is nothing more than a proper detail, it is worthy of observance.

In this instance, as in many others, there is a lack of authentic information upon both sides of the question, and it is this deficiency which renders it impossible to form an abiding judgment. "There is need of more definite information on many of the most essential points of surgical treatment, and in particular for that full and definite comparison between the results of antiseptic and of ordinary surgery, which has been so long asked for by those who are neither enthusiasts nor opponents of the method, but who want to do their duty to their patients."

Mr. Savory's address has already attracted the attention of the advocates of Listerism, and a correspondence has appeared in the *Lancet* from the pen of J. Greig Smith, Surgeon to the Bristol Royal Infirmary. It seems quite probable that the address will give rise to an extended discussion.

The saving of human life should be made the essential element in the great art of medicine and surgery.

VIOLATION OF THE CODE.

SCARCELY a week passes in which we do not receive one or more complaints or reminders that there has been an infraction of the code. There are those who feel aggrieved because medical men persist in lending their hard-earned and questionable fame to sustain the virtues of lager beer. There are others whose spinal columns arch at the fact that certain pseudo-eminent surgeons have become consultants to homeopathic hospitals; and there are still others, young in the profession, who have had a temporary attack of exophthalmos because some old and honored member of the regular school, and in good standing in his County Medical Society, has consulted with eclectics, homeopaths, and others of like ilk, and has allowed his name to enter the columns of the village newspaper in what seems to be an undignified, unprofessional, and under the aroma of the code, in an illegal manner. One young man, who recently graduated from a respectable medical college, where he listened to the old story of our "glorious and honorable profession," holds his hands up in horror at what his ears have heard, his eyes have beheld, and his warm heart has felt. He asks for advice. He is perplexed; he is annoyed; and, judging from his pathetic appeal for aid, he is disgusted. It is very evident from the tenor of all these complaints that violations of the code are eye-sores to the complainants; they are like a picture hanging askew on the wall.

For their comfort and encouragement it may be said that there is a way out of their embarrassment, which

perhaps may seem thorny, but it is narrow, direct, and will ultimately lead them to clear and unobstructed professional sailing. It is a time-honored principle in the practice of medicine to first, if possible, remove the cause of disease. This principle may be relied on in dealing with questions of medical ethics with the same degree of safety as in dealing with the manifestation of germs, infectious elements, or chemical compounds. Provisions have been made for the radical treatment of all such cases of individual indiscretion or personal attempt at setting at defiance established regulations, and the machinery for correcting the violations of which complaint is made is within the reach of the humblest physician. A court of inquiry and trial exists in each County Medical Society in the State, and from these an appeal can be carried to the State Medical Society, and it is fair to presume that when a case of direct violation of the by-laws and the constitution of these societies or of the code of medical ethics is presented, that each offender will receive the attention he merits. Let the offended promptly complain before the local tribunal; let the local tribunals be thorough, impartial, energetic, and scrutinizing in sifting the evidence brought; and let the higher authority be honorable and uncompromising in establishing the ends of justice, and there will be far less cause for murmuring than at present seems to exist. This is a method of removing these excrescences which is effectual, direct, and radical, and we will add that it is the duty of those who live in the midst of such abnormalities to set their own house in order, and be as faithful in cleansing it as though they had been exposed to the virus of yellow fever. Thorough purgation in the present instance first, and disinfectants afterward.

HONOR TO DR. LONG.

We furnish our readers a brief correspondence relating to the presentation of a portrait of Dr. Crawford W. Long to the Georgia Legislature, in Atlanta, August 22, 1878. A few years ago Dr. J. Marion Sims revived the discussion upon the discovery of the anæsthetic properties of sulphuric ether, and gave the credit to Dr. Long, who, at the time the discovery was made, was a resident of Jackson Co., Georgia. The movement initiated by Dr. Sims has culminated in the presentation of a fine portrait of the discoverer to the Alumni Association of the University of Georgia, which, in turn, presented it to the Legislature of the State of Georgia, and it is to be retained in the Hall of the House of Representatives.

The movement has already given rise to discussion, and it may be that this whole subject will again be brought before the profession and the world.

A NEW MEDICAL SCHOOL is to be established in Edinburgh in connection with the new university. The buildings are now being erected.

Reports of Societies.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

Third Annual Meeting, held in the City of New York, August 26th, 27th, and 28th, 1879.

TUESDAY, AUGUST 26TH—FIRST DAY.—MORNING SESSION.

THE Association met at Park Avenue Hotel, and was called to order by the President, Dr. L. A. Duhring, of Philadelphia.

At 9.30 A.M. a business meeting was held at which the Report of the Council was presented, the Nominating and Auditing Committees appointed, proposals for active and honorary membership made, and miscellaneous business attended to. There were present during the sessions of the Association the following members: Drs. Louis A. Duhring and Arthur Van Harlingen, of Philadelphia; I. E. Atkinson, of Baltimore; J. N. Hyde, of Chicago; W. A. Hardaway, of St. Louis; C. Heitzmann, R. W. Taylor, L. Duncan Bulkley, H. G. Piffard, George N. Fox, and Frank P. Foster, of New York; J. C. White and Edward Wiglesworth, of Boston, and S. Sherwell, of Brooklyn.

The first thing on the regular programme was the address of the President, Dr. Duhring, which showed great labor in its preparation, and the subject of which was

THE RISE OF AMERICAN DERMATOLOGY.

In tracing the history of the science he gave an exhaustive résumé of all the earlier literature on the subject, and afterward a chronological narration of the establishment of all chairs devoted to the subject in the principal colleges and of special institutions for skin disease, as well as of the skin departments of the various large hospitals and dispensaries. Among the works referred to are the following: "A Brief Guide in the Small-pox and Measles," by Thomas Thatcher, which appeared in 1677, and is believed to have been the first medical book ever published in this country. The author of it was well known, not only as a learned physician, but also as a divine. A work on Cancer by Lieut.-Governor Cadwalader Colden, a man of great learning and high attainments, and also author of a volume on the Climate of New York, which is better known than the other. "An Essay on the Causes of the Different Colors of People in Different Climates," a long and elaborate treatise by John Mitchell, of Virginia, which is said to have been the first work ever published on the subject. Dr. Mitchell was also the author of a brochure on yellow fever as it prevailed in Virginia in 1741. "An Essay on the Causes of the Variety of Complexion and Figure in the Human Species," by Samuel Stanhope Smith, President of the College of New Jersey (1787). The book attracted a considerable amount of attention in Europe, and contained an account of the case of the negro, Henry Moss, of Maryland, who during a period of twenty years underwent a change of color from a deep black to a clear and healthy white. "An Experimental Dissertation on the Rhus Vernix, Rhus Radicans, and Rhus Glabrum," an able and exhaustive work by Thomas Hanfield. A "Dissertation on Perspiration," by James Agnew, of Princeton, New Jersey (Philadelphia, 1800), an essay of unusual excellence. "On the Warm Bath," by Dr. Lochette, of Virginia. "The Lues Venerea: the Modus Operandi

of Mercury in curing Gonorrhœa," etc., by James Tongue, of Maryland, in which the author endeavored to prove that syphilis was not introduced into Europe from America, and that syphilis and gonorrhœa were two distinct forms of disease. "A Prospect of Extirminating the Small-pox," and a paper on the Cow-pox Virus, by Dr. Waterhouse, of Cambridge (1800). "The Jennerian Discovery," by C. R. Aiken. "The Structure of the Skin, with a View to the Diagnostics and Cure of Diseases usually denominated Cutaneous," a Boyleston prize essay by George S. Shattuck, of Boston.

On the second of June, 1836, the "Broome Street Infirmary for Diseases of the Skin" was established in New York, with Drs. H. D. Bulkley and John Watson as physicians in charge. The following year a course of lectures on Dermatology was given at the Broome Street School of Medicine, by Dr. Bulkley, who had fitted himself for the work in Europe, and this was the first ever delivered in America on this subject. About the year 1830 the Medical Department of the University of Pennsylvania came into possession of a large and fine collection of models of skin disease, which had been purchased in Europe by Prof. George B. Wood, and this was the first treasure of the kind that was ever brought to this country. In 1861 Dr. J. C. White, the honored ex-president of the Association, gave the first course of lectures on Dermatology in Harvard University, and shortly after the close of the war chairs in this department were established in all the medical colleges of New York, Philadelphia, and other large cities. The New York Dermatological Society, an organization which has exerted so marked an influence on the study of skin disease, was founded in 1869, with Dr. H. D. Bulkley as its first president.

The first regular paper was one by Dr. I. E. ATKINSON

A CASE OF INCOMPLETE VITILIGO.

The patient was a dark mulatto woman, twenty-five years of age, who had first noticed the affection under consideration four years before. Her skin presented peculiarities having the same relation to acquired leucoderma or vitiligo as the case described by Captain Burton, the African traveller, of which Beigel speaks, bears to congenital leucoderma, or albinism. The trouble was very extensive: the back of the hands, the forearms, arms, neck, breast, abdomen, buttocks, thighs, and, indeed, nearly the whole surface except the face, scalp, and back being affected. These various portions were sure to be colored in different shades. First there was a dark one, which formed the ground color, and was the normal hue; then there was a still darker ring bordering the vitiliginous patch, and finally a central much lighter shade which involved an immense number of irregularly distributed, discrete and confluent spots. Upon the neck and breast these spots were comparatively few; but here, in addition, there were a number of vertically running atrophic striae of an abnormally light color, such as are commonly seen upon fat persons and on the abdomen after pregnancy. There was no difference to the touch between the normal portions of the skin and that affected with the vitiligo, and the æsthesiometer showed that there was no deficiency of sensibility in the latter. Beyond some anxiety on account of the discoloration of the skin, the patient did not seem to have any subjective symptoms.

No result was produced by any therapeutic measures; but, curiously enough, it was noticed, while the case was under observation, that in certain portions of the body (notably the backs of the hands) there was first

the complete absence of deficient coloration, subsequently the existence of the vitiligo, and, finally, its complete recession from these parts. The hairs, although not abundant anywhere over the surface, were not less numerous upon the affected spots of skin than in other portions of it, and remained unchanged in color.

Dr. WHITE considered it a matter of importance that this restoration of pigmentation should have taken place under the notice of a reliable observer, and said that he believed it to be the first instance of the kind which had been recorded by such.

Dr. TAYLOR referred to the case of a Dr. Burdick, of Vermont, who has leucoderma of the hands every summer, which, however, begins to disappear as the cool weather of autumn comes on, and is entirely absent during the winter.

Dr. BULKLEY stated that he had seen but one case of leucoderma in which the hairs remained entirely unaffected in color; and Dr. Fox remarked that he thought this case of Dr. Atkinson's explained many of the cases in which the disease has disappeared and reappeared, as well as those in which the hairs were in a variable condition. In the complete form he was inclined to believe both that the hairs always turned white, and that no return of pigmentation ever took place. Of course it was always a difficult matter to say in any given case whether there was really a complete absence of pigment. One case which he had seen was of great interest, as it was one of combined melanoderma and vitiligo, there being *increase* of pigment before it began to disappear; and he thought that this was perhaps the general rule. After some further discussion by Dr. Sherwell and Hardaway, a paper entitled

A CONTRIBUTION TO THE STUDY OF THE BULBOUS ERUPTION INDUCED BY THE INGESTION OF IODIDE OF POTASSIUM,

was read by Dr. HYDE, of Chicago. The case which gave occasion for his writing it was remarkable not only in being an instance of a very rare affection, but also on account of the age of the patient, an infant at the breast eight months old. It had been troubled with chronic eczema capitis, and about a month before Dr. Hyde was consulted in reference to it, an immense number of boils came out upon its head. It was on account of the latter that the physician in charge ordered the iodide of potassium; the quantity taken being five grains a day. When the bulbous eruption known as hydroa made its appearance, he discontinued the iodide (although until the suggestion was made to him by Dr. Hyde, it had not occurred to him that this new difficulty was due to that cause), and it at once began to decrease. In view of the points elicited by a study of this and all the other reputed cases that he was able to collect, Dr. Hyde came to the conclusion that some of Tilbury Fox's opinions in regard to this disorder could only be accepted with reserve in the light that we can command upon the subject at the present time. The most valuable of the practical deductions to be made from his case, Dr. Hyde considered to be: That both in eczema and acquired syphilis, when a distinctly vesicular or bulbous eruption becomes suddenly apparent, the lesions intermingled with those characteristic of the disorders named, in the person of patients who have been under inexperienced practitioners, the possibility that the iodide of potassium has been previously administered should be carefully estimated.

A discussion of great interest followed the reading of this paper, and was participated in by Drs.

White, Taylor, Wigglesworth, Van Harlingen, and Duhring.

On motion of DR. BULKLEY the thanks of the Association were unanimously tendered the President for his able and valuable paper.

On motion of DR. WIGGLESWORTH, it was decided that the Association should devote the afternoon of Thursday, August 28th, to an inspection of such cases of interest as the various members might like to present, and on motion of DR. HYDE, that a committee of two should be appointed by the chair to select a suitable place for the purpose, Drs. Bulkley and Taylor were the gentlemen selected to constitute this committee.

FIRST DAY—AFTERNOON SESSION.

The first paper in order was one by DR. BULKLEY ON TWO CASES OF CHANCER OF THE LIP, PROBABLY ACQUIRED THROUGH CIGARS.

Both of the sufferers in these cases were physicians of skill and intelligence, and they were each entirely unable to trace their syphilitic trouble to any other source of infection than the above.

DR. HEITZMANN, in commenting on one of these cases which he had personally seen, stated that the sore in the mouth was to all appearances nothing but a chancre, and that there was also a similar lesion on the penis, which had been caused by matter carried from that in the mouth by means of the hands. In view of facts like this, he thought that the doctrine of duality was no longer tenable, as, indeed, Hebra and other high authorities had long ago concluded.

DR. BULKLEY attributed the absence of hardening to the fact that at the time referred to by DR. HEITZMANN the patient had been taking mercury for three weeks; and he also stated that in his experience he had not found chancres on the lip so hard as those on the prepuce.

Both Drs. WHITE and TAYLOR were of the opinion that the evidence which Dr. Bulkley had adduced was hardly sufficient to prove that the two physicians whose cases he had related had become infected with syphilitic poison in the manner indicated. Dr. Taylor also stated that he was very much startled by Dr. Heitzmann's remarks on the subject of dualism. As for himself, he believed that as sure as there was a sun in the heavens, there were two forms of disease, and he then proceeded to mention some of the investigations by the most distinguished authorities, on which the so-called dualists based their opinion. After some further remarks by Drs. Atkinson, Wigglesworth, and Bulkley, Dr. Fox read a paper on

THE TREATMENT OF ECZEMA AND ULCERS OF THE LEG BY AN ELASTIC TUBULAR BANDAGE.

This bandage was to be applied by slipping it over the foot on to the leg, the limb having first been oiled; and among the advantages claimed for it were, its lightness, the equal pressure which it exerted, the saving of time and trouble (since it was not necessary to remove it in order to clean the parts), and its cheapness, due to the fact that so little rubber was required in its construction.

The third paper during this session was by DR. HEITZMANN, on

MICROSCOPICAL STUDIES ON INFLAMMATION OF THE SKIN,

in the course of which he stated that his observations had led him to the following conclusions:

First. In epithelium the first step of the inflammatory process consists in an increase of the living

matter, both in the protoplasmic bodies and between them; the former producing the coarse granulations of the epithelia, and the latter the thickening of the so-called "thorns" in the current substance. Any particle of living matter both in the epithelia and between them, through continuous growth, may lead to a new formation of epithelia, with the termination in hyperplasia of epithelium. (Seen in psoriasis, squamous eczema, horny formations, etc.)

Second. In connective tissue the first manifestation of the inflammatory process is the dissolution of the basis substance and reappearance of the protoplasmic condition. By this process and the new formation of medullary elements, which may start from any particle of living matter, the inflammatory infiltration is established. The sum total of the inflammatory elements, which remain united with each other by means of delicate offshoots, represent an embryonal or medullary tissue. If the new formation of medullary elements be scanty, the resolution is accomplished by reformation of basis-substance. (Seen in erythema, erysipelas, etc.) If, on the contrary, the new formation of medullary elements be profuse in new formation, connective tissue, or hyperplasia, will result. (Seen in scleroderma, elephantiasis, etc.)

Third. The plastic (formation) inflammation may be accomplished by the accumulation of a larger amount of serous or albuminous exudation in the epithelial layer (seen in miliaria, sudamina and herpes), or in the connective tissue of the derma (as in urticaria). In both instances complete resolution will ensue.

Fourth. Suppuration in the epithelial layer of the *rete mucosum* is produced by an accumulation of an albuminous or fibrinous exudation, by which a number of epithelia are destroyed, and by new formation of pus-corpuscles from the living matter of the epithelial elements themselves. Epithelial suppuration heals without the formation of a cicatrix. (Seen in eczema matidans, impetigo, and pemphigus.)

Fifth. Suppuration in the connective tissue of the derma results from the breaking apart of the newly formed medullary elements, which, being suspended in an albuminous or fibrinous exudation, now represent pus-corpuscles. Pus is a product of the inflamed connective tissue itself, and always a result of destruction of this tissue. Suppuration of the derma invariably heals through a cicatrization. (Seen in abscess, furuncles, acne, ecthyma, and variola.)

ELECTION OF OFFICERS.

At the business meeting preceding the regular morning session on August 27th, it was voted that the meeting of the Association next year should be held at Newport, and the following officers were elected: President, Dr. Louis A. Duhring, of Philadelphia; Vice-Presidents, Drs. Edward Wigglesworth, of Boston, and W. A. Hardaway, of St. Louis; Secretary, Dr. Arthur Van Harlingen, of Philadelphia; and Treasurer, Dr. I. E. Atkinson, of Baltimore.

(To be concluded.)

THE MORAL EFFECT OF POPULAR BEVERAGES.—According to Dr. Boeck, of Leipsic, tea and coffee produce nervousness and peevishness, e.g., the snappishness of the Chinese and the hypochondriasis of bibulous ladies; beer brutalizes, wine impassions, whiskey infuriates, but eventually unmans. Alcohols in general, when combined with a fat and flesh diet totally subjugate the moral nature. Chocolate alone is an innocent drink.

OBSTETRICAL SOCIETY OF LONDON.

W. S. PLAVFAIR, M.D., F.R.C.P., PRESIDENT, IN THE CHAIR.

(FOR THE MEDICAL RECORD.)

THE USE OF THE FORCEPS AND ITS ALTERNATIVES IN LINGERING LABOR.

The noteworthy debate inaugurated in the London Obstetrical Society by Dr. Robert Barnes has been continued. The fair and impartial discussion which this question has received at the hands of those thoroughly competent to speak upon the subject must carry with it practical and permanent benefit to the whole profession.

In the very able paper read by Dr. Barnes, the following propositions were presented as likely to give rise to an expression of differences of opinion:—1. In lingering labor, when the head is in the pelvic cavity, the forceps is better than its alternatives. 2. In lingering labor, when the head is engaged in the pelvic brim, and when it is known that the pelvis is well formed, the forceps is better than its alternatives. 3. In lingering labor, when the head is resting on the pelvic brim, the liquor amnii discharged, and it is known that there is no disproportion or only a slight disproportion, even although the cervix is not fully dilated, the forceps will generally be better than its alternatives. 4. In proportion as the head is arrested high in the pelvis, in the brim, or above the brim, the necessity, the utility, and safety of the forceps becomes less frequent. 5. As a corollary from the preceding proposition, increasing caution in determining on the use of the forceps, and greater skill in carrying out the operation, are called for.

At the next regular meeting following that in which the paper was read, the discussion was opened by Dr. Edis, who remarked, with reference to expectancy, that unfortunately too much was expected of the patient and too little of her attending physician. Not infrequently is the woman, at the commencement of her labor—a really trying process that calls for an immense expenditure of muscular force—found without proper preparation, having for a long time, perhaps, had only disturbed sleep, partial digestion, and improper performance of body functions.

But, on the supposition that she is as well prepared as possible for her ordeal, there is much that can be done in seeing that an actual waste of her physical power does not occur. On this basis it was argued that the judicious use of the forceps was an aid which supplemented the defective efforts of nature, and that the medical attendant therefore should not look upon instrumental delivery as a *dernier ressort*.

So soon as there is any general evidence, as established by the condition of the pulse, power, and pains, that the woman has a task which she cannot readily perform, it is the duty of the accoucheur to prevent her from falling into powerless labor. Under such circumstances recourse may be had to the simple means of affording aid by external pressure over the uterus, which Dr. Atthill regarded as unscientific and calculated to be injurious, or by applying the binder; but these having failed to give prompt relief, the forceps should by all means, says Dr. Edis, be used in preference to ergot.

It has been a belief, extensively accepted, that a prolonged first stage of labor does not entail danger upon the mother and the child. Dr. Edis gave an emphatic negative of this proposition—regarding the woman as in the first stage until the os is completely dilated—and cited cases in confirmation of the view

entertained. As bearing upon the treatment of such cases, Dr. Barnes asked, "Is the application of the forceps ever necessary or useful before the full dilatation of the cervix uteri?" To this question Dr. George Johnston replied that in cases in which the liquor amnii had escaped at the commencement of labor, and before the os is fully dilated, the forceps are necessary and useful to avoid the danger to the mother which accrued from pressure of the child's head, especially if there is any delay with the head at the brim. Even though the membranes are not ruptured, the timely use of the forceps under such circumstances may save the woman's soft parts from inflammation and sloughing. Instrumental delivery at this stage certainly saves the child from the danger incident to compression of the placenta and consequent death from obstructed circulation. At the same time, Dr. Johnston is very strong in his statement that the application of the forceps and traction through an undilated os is justifiable only when such an os is dilatable. The conclusion reached by Dr. Johnston was that, in course of time, the forceps in skilful hands will prove to be of the greatest advantage in saving the life of both mother and child.

From November, 1875, to May, 1879, 3,958 women were delivered in the Rotunda Hospital, Dublin. From the experience which Dr. Lombe Atthill obtained during that period, as master in that institution, he thinks that no practitioner of experience should say that the forceps should not be used because the os is not fully dilated, although under such circumstances the instrument should be employed as rarely as possible. When the os is not fully dilated, Dr. Atthill objects to the use of the forceps, no matter where the head is, unless the condition of the mother calls for its use. He feels satisfied that the danger from the use of the forceps, before the os is fully dilated, is underestimated by some because they fail to distinguish between two very different classes of cases. In some cases the os is so soft and easily dilatable that delivery is effected with the greatest possible ease and safety, although a most unjustifiable procedure. The cases to which he refers are those familiar to every physician with any extended obstetric experience, in which a uterine pain will cause the os uteri to all but disappear, yet, as the pain subsides, the head speedily recedes and the os contracts to the same size as before. These cases, manifestly, are to be placed among those in which the os is dilatable, and in them the use of the forceps, by unanimous consent, is easy and safe, and may be justifiable. "But," says Dr. Atthill, "it is far different with another class of cases," and from this point he discusses the question with reference to an "undilated cervix" which often opposes delivery. The danger in attempting forceps delivery in cases of undilated cervix has induced him to avoid the use of the instruments, when possible to do so, until the os uteri is fully dilated. In cases, however, in which delivery is imperative before the os is dilated, he does not hesitate to use the forceps in preference to employing version, notwithstanding the obstacle to easy delivery which an undilated cervix may offer. His practice, then, is to use the forceps when the head is low and the os fully dilated; but when the os is not fully dilated, he uses the instruments with the greatest possible hesitation.

With reference to ergot its use is prohibited in the Rotunda—and abdominal compression and introduction of the fingers into the rectum Dr. Atthill regards as unscientific and most irksome both to the patient and practitioner. The use of the forceps before the os is fully dilated, where there is some difficulty of extrac-

tion, he believes does not contribute much to saving the life of infants.

The discussion was continued by Dr. McClintock, who confined his remarks to the use of the forceps in the high and the low operations. Dr. McClintock, like Dr. Barnes, cautiously and wisely avoids drawing fixed conclusions, and discards such statistics as we have as almost valueless. Contrary to the belief expressed by Dr. Edis, Dr. McClintock states, "It is one of the most generally true maxims in midwifery, that so long as the membranes are entire and the liquor amnii present, no danger will accrue to either mother or child by the continuance of the labor process, except from convulsions or hemorrhage."

It is important, therefore, in speaking of the first stage of labor, to bear in mind the presence or the absence of the liquor amnii, as all readily admit that the use of the instruments in this stage, in purely lingering labors, is especially influenced by the absence of the amniotic fluid. Dr. McClintock, in opposition to the practice of Dr. Johnston, entirely dissents from using the forceps while the membranes are intact. In his estimate of the value of the forceps in the high operation, he agrees mainly with Dr. Barnes in the statements that the necessity for this operation is not frequent; that it is not without danger in skilful hands; and that extra judgment and skill are required in deciding upon and carrying out the operation when the head is high above the brim, and the os uteri is only imperfectly dilated. Under the last circumstances he entirely disapproves of the use of ergot. But when the head is in the pelvis, and there is no mechanical obstacle to its expulsion, ergot in his hands has acted most satisfactorily, and, in opposition to the statement made by Dr. Barnes, he does not object to its use. His position is that it does the child no harm if it does not produce uterine contraction; if it does excite the uterus to action it involves danger to the child, to be sure, but it expedites labor to such an extent that timely interference rescues the child, hence it is preferable to the forceps.

This is the position assumed by a man of deserved reputation and great experience, and yet it carries with it an element of danger which needs careful watching, and the forceps may be required to effect a safe escape. This Dr. McClintock recognizes, for he says that if the drug fails to deliver prompt enough, the accoucheur is just as capable of delivering with the instruments as if it had not been given.

With reference to the low operation he believes that, notwithstanding the too frequent use of the forceps at the present time, the policy of procrastination formerly employed lacks the advantages which obtain in the more frequent use of the instruments.

Dr. Basset agrees substantially with Dr. McClintock regarding the use of ergot, and thinks the charge against the drug has been somewhat overdrawn. If the ergot fails to produce the desired result—prompt delivery after the head has reached the floor of the pelvis, if there is no mechanical obstacle—the forceps can at once be employed.

Although the os—he makes no discrimination between os and cervix—is only partially dilated, he thinks less harm will come to the patient by the use of the forceps if the operation is prudently undertaken, than if other methods of treatment are employed.

In speaking of the resistance offered by a rigid cervix uteri to the progress of labor, Dr. Henry Bennett holds that it is always due to pathological conditions, such as chronic inflammation; hence the inutility of many of the agencies resorted to for overcoming it.

A former assistant-master of the Rotunda Hospital, Dr. Cranny, holds that there are many cases in which the necessity for the early use of the forceps exists, especially to prevent undue exhaustion, and sloughing and its consequences, but the suitable cases are those in which the os uteri is dilatatable and soft, and the cervix is not rigid. The safety of this rule is apparent, and it conforms to views held generally by those who participated in the discussion.

Throughout the discussion there is the same notable absence of statistics bearing upon the condition of the woman subsequent to instrumental delivery, as was manifest at its commencement. The statistical information given bears upon the life of the mother and the child. Under this head Dr. Cranny refers to statistics to show that the early use of the forceps has decreased the number of craniotomies, and has contributed to the saving of the life of the child.

One can readily see, however, that statistical information must be of the purest quality to be of practical value to the general practitioner who, in the same day, perhaps, may be called upon to operate for strangulated hernia, amputate a leg, treat a case of ophthalmia neonatorum, remove a foreign body from the ear, and deliver a child by means of the obstetric forceps; for rules may be framed out of statistical evidence and medical testimony that will, in the hands of one man, yield results not only highly beneficial, but entirely innocuous, while in the hands of another they will be equally dangerous and undeserving of adoption. The mechanic of only ordinary skill must be restricted by rules which for the expert are entirely unnecessary. Hence the difficulty in giving general rules for the guidance of the general profession, which embraces among its members a subsequent disputant who had attended lingering labors, during the last twenty-five years, in a maternity hospital, which he acknowledges is a small one, in which the patients did "very well" without the forceps, although the parturient process lasted perhaps two days.

Dr. Roper, in speaking of the application of forceps in the first stage of labor, that is, in cases in which dilatation of the os goes on slowly while it receives the pressure of the bag of membranes, or the presenting head, when the liquor amnii is discharged, remarked that he had not seen the absolute necessity of delivery by forceps when the os is only partially or even four-fifths dilated, in order to avoid serious consequences to the maternal structures and danger to the life of the child. In a case of simple labor, prolonged only by a physiological rigidity of the os uteri, Dr. Roper has not seen evil results from a protracted first stage of labor. Such results are not liable to occur for the reason that, even though the membranes be ruptured and the liquor amnii discharged, there is no continuous pressure. Persistent contraction and impaction of the head do not, says Dr. Roper, occur in connection with the first stage of labor.

From Dr. Collins' and Dr. Roper's experience we derive the practical observation that "the death of the child, as a rule, precedes injury to the maternal structures," so that if the foetal heart can be heard it is presumptive evidence of the safety of the soft parts of the mother.

If this be true, it seems to us that some other explanation must be given for the frequent occurrence of vesico-vaginal fistule than that which, in this country at least, has a somewhat general recognition, namely, delayed delivery after impaction of the head occurs; for this lesion exists in numerous cases in which the child was still-born.

With reference to the frequent use of the forceps in

the first stage of labor only when the os is dilatable, seems, according to Dr. Roper, to be unnecessary, because the head of the child will soon expand it and allow delivery to take place. He also disapproves of the practice of carrying the obstetric forceps to every case of labor, and using the instrument without the existence of any factors of difficulty, simply for the purpose of diminishing maternal suffering. For he believes that such practice carries with it risks of liability to post-partum hemorrhage, and the gynæcological work that follows interference with the natural functions of the uterus in child-birth.

In speaking of the use of the forceps in the *second* stage of labor, he gives the result of his observations in two classes of cases:

First, those in which everything seems to be favorable to a quick delivery; the soft parts are lax, the child's head lies loosely in the pelvic cavity, and the labor is protracted simply through uterine atony. Such cases he believes always terminate naturally by expectancy; but if importunities of friends, or other apparently uncontrollable circumstances force a forceps delivery, it should be accompanied by the subcutaneous injection of ergotine. He uses ergot, not as an alternative of the forceps, but as an adjuvant.

In the *second* class of cases the features of the labor are just the opposite of those just described; the women are usually primiparous, the uterus acts powerfully, the pains are frequent, regular, and of an expulsive character, and the expulsion of the child is resisted by the tonicity of the soft parts of the outlet of the parturient passage. Every obstetrician can recall such cases, in which the head, with every pain, is forcibly crowded against the soft parts, the perineum becoming distended to the thinness of parchment, and yet it does not pass over. The pain ceases, the head retreats, all tension is relieved, the placental circulation is restored, and then another pain comes, and so the case goes on, nature admirably using the force, little by little, which is to relax the rigid soft parts and mould the foetal head. So long as the uterus continues to act forcibly and rhythmically, the indication for the use of the forceps has not arrived, but when warned by less movement of the head, by less forcible uterine contractions, the instrument should be used, and not allow the labor to come to a cessation. Experience teaches the obstetrician to anticipate such a dead-lock, and to resort to artificial delivery before the crisis arrives.

An important feature of Dr. Roper's remarks is the statistical argument which he makes against the frequent use of the forceps, based upon the practice in the Rotunda Hospital during the masterships of Dr. Collins and Dr. George Johnston. The former used the forceps but very rarely, 1 in 608; while the latter employed them very frequently, 1 in 10; and the results seem to prove that the frequent use of the forceps does not tend to save the life of either the mother or the child. As already stated, however, statistics are so liable to be varied by uncontrollable influences, that arguments based upon them must be looked upon with suspicion.

Dr. Braxton Hicks gives a prompt and affirmative answer to the question, "Does lingering labor occur, so as to entail danger to the mother and child during the first stage of labor?"

The cases in which he recognizes this danger are those attended by trismus of the uterus, the fetus being held for a long time after it should have been delivered. It is in such cases that he admits the use of the forceps even before dilatation of the cervix, but holds the reserve that "how often" is a matter of

further consideration. He believes that death is not likely to occur in a woman from simple detention in the first stage, so long as the pulse remains of normal frequency, and that interference under such circumstances is apt to be followed by such complications as retention of the placenta, lax uterus, and hemorrhage; at all events, there need be no fear or dread that the woman will die of exhaustion. When, however, a condition of trismus is developed, and the uterine contraction passes into the interval between uterine pains, the time for interference has arrived, and then the milder alternatives, opium, slight anæsthesia, may be tried, certainly not ergot, and if these do not produce relaxation resort should be had to traction.

With reference to the *second* stage, he puts a hypothetical case; suppose the uterus to be at work, the pains at the maximum, and an obstacle occurs; then if it is known that a small amount of traction will bring the child out quickly, he believes it to be beneficial to the mother and certainly to the child to abstract it gently and quietly, but to draw out the child when the uterus is not responsive is one of the most critical things that can be done. He assents to Dr. Barnes' fourth proposition. Dr. Cleveland assents to the same proposition with its corollary, believing that it means that the operation shall not be lightly undertaken. He is of the opinion that it is pretty generally accepted that when the head is well in the pelvis, no progress is being made, no obstacle exists, and the obstetrician is satisfied that the uterus has done its best, the forceps is better than any of its alternatives. He favors the employment of the long forceps, and while he regards it as rare indeed that an operation is required for a purely lingering labor, he does not believe that mischief is likely to accrue to the woman by the skilful use of the instrument, if necessary to employ it. He uses the long forceps for the reason that there are cases in which the arrest is above the brim, and although the os is not well dilated, service is done by the use of the instrument, while to wait until the head comes within reach of the short forceps is positively detrimental.

Dr. Daly, from an experience obtained by an attendance in 1,700 private cases, reaches the conclusion that when the head is below the brim of the pelvis there need be no limit to the frequency with which we may apply the forceps, so as to save the suffering woman from unnecessary pain, without increasing in any degree the risk to mother or child.

Dr. Graily Hewitt agrees with Dr. Hicks, and answers in the affirmative the question: Does lingering labor occur so as to entail danger to the mother and child during the first stage of labor? Is the application of the forceps ever necessary or useful before the full dilatation of the cervix uteri? In answering this question Dr. Hewitt turned attention to the definition of the termination of the first stage of labor, an important point, and one overlooked by the speakers by whom he was preceded, and although he does not give a direct definition himself, yet we are left to infer that it is marked by a dilatable os, and without special reference to the position of the head. With very few reservations, he believes that when the membranes are unruptured, the first stage may be allowed to go on a considerable length of time. With reference to the broad question as to the use of the forceps, Is it a good thing that the forceps should be largely employed, or is it proper that their use should be greatly restricted? he sympathizes with those who contend that the instruments should be largely employed, and he encouraged the use of the forceps much more frequently than has been the cus-

tom; for the dexterity which should be acquired in the performance of the simpler operations will invariably lead to qualifications sufficient to allow dealing with the difficult and dangerous cases. Another important point brought out by Dr. Hewitt was that it did by no means follow that, after the application of the forceps, the delivery should be made to occur as rapidly as possible. By instant extraction much mischief may be done, for the instrument is intended simply to supplement nature.

Dr. Swayne's experience leads him to three conclusions: *First*. That the use of the forceps is proper and safe before the os is fully dilated, when there is any arrest which prevents it descending upon the os uteri; but in his opinion the use of the forceps is improper when the delay arises simply from rigidity, and not from arrest of the head. *Second*. In cases in which the head is arrested at the brim of the pelvis, and the pelvis is normal and not irregular in shape, as a general rule the forceps is preferable to turning. *Third*. When the pelvis is irregular, and the head very high above the brim, turning is preferable to the forceps.

The President of the Society, Dr. Playfair, again pointed out what he has always directed attention to whenever speaking of the use of the forceps, namely, that instrumental interference should be resorted to with frequency only in one particular class of cases, and that is, the cases in which the head is arrested low down in the cavity of the pelvis or on the perineum, and in which only a slight *vis à tergo* is required to effect delivery. The high operation he regards as one to be approached with the very greatest hesitation. With reference to ergot as an alternative he thinks there is hardly any fact in medicine more certainly proved than the immeasurable superiority of the forceps in effecting delivery in retarded labor. Dr. Playfair also speaks strongly in favor of the use of the forceps to relieve the woman of hours of horrible suffering.

According to his experience the cases in which it was necessary, or even contemplated, to use the forceps with an undilated os, are of very great rarity. Again, regarding systematic pressure to the uterus, he did not agree with Dr. Roper, but believed that the very greatest possible advantage may be obtained from it.

In closing this most important and useful discussion, Dr. Barnes alluded to one or two points upon which there was a unanimity of opinion, and their reproduction will be of value.

The head of the child should not be allowed to remain in the pelvic cavity very long. To this there was a general assent. At the same time, Dr. Barnes thought it not good practice to put in the forceps as soon as the head is within reach, as recommended by Dr. Daly, and some others. So long as the uterus is acting fairly without spasmodic action, the head advancing slowly and the parts relaxing, and it is evident that the woman will be delivered within a few hours without notable tax upon her powers, and so long as the pulse is quiet and regular, the use of the forceps is not judicious.

With reference to ergot, the majority of those who participated in the discussion disapproved of its use to terminate a lingering labor. Dr. Barnes was especially emphatic upon this point, and while he admits its use when the head is nearly on the point of being born, he believes that in any of the higher cases it will not do anything which cannot be done more effectively and more safely by the forceps.

Three eminent gentlemen—Dr. Hicks, Dr. Hewitt, and Dr. Barnes—agree that lingering labor occurs in

the first stage of labor, and in those cases expectancy is bad if trusted to alone. In such cases Dr. Barnes allays the muscular spasms of the uterus by the use of nitrite of amyl, puts in the forceps and delivers the woman. He says that this remedy is superior to either chloroform, chloral, or opium, which are valuable in the order named. In conclusion, he remarks that the utility, the necessity, and the safety of the forceps becomes less frequent as we ascend above the pelvic brim; but in the use of the instrument we have not advanced so far as to realize the scientific dream of Dr. Tyler Smith, that craniotomy is on the point of abolition. Craniotomy, however, as an alternative of the forceps, will diminish more and more as skill is acquired in the use of the forceps, and as the instrument is improved and given more power.

Notwithstanding the immense value of the forceps, it must not be forgotten that it is an instrument that is liable to great abuse, and the thanks of the profession are due to Dr. Barnes for inaugurating a discussion upon so practical and important a subject.

Correspondence.

THE PORTRAIT OF CRAWFORD W. LONG.

ITS PRESENTATION TO THE GEORGIA LEGISLATURE, IN ATLANTA, ON AUGUST 22, 1879.

ADDRESS OF SENATOR GORDON IN BEHALF OF THE DONOR, MR. H. L. STUART, OF NEW YORK.

(Special correspondence of THE MEDICAL RECORD.)

At an early hour on Friday, August 22, 1879, the galleries of the House of Representatives of the Legislature of the State of Georgia were filled with a brilliant assemblage of ladies and gentlemen, to witness the ceremonies of the presentation of the magnificent portrait of Dr. Crawford W. Long, a native of Georgia and the discoverer of the anæsthetic properties of sulphuric ether.

The painting is pronounced by competent observers a magnificent and faithful specimen of art portraiture, and seems a living reality to those who knew best the calm, thoughtful face of the physician whom it represents.

It is the generous and noble gift of Mr. H. L. Stuart, of New York, and was presented through Hon. J. B. Gordon, a member of the Alumni Association of the University of Georgia, and United States Senator.

At 11 A.M., General Gordon, Governor Colquitt, Senator Hill, and others, escorting the female relatives, wife and daughters of Dr. Long, entered the hall, preceded by the Senate in a body.

Speaker Bacon introduced General Gordon, who prefaced his presentation address by the following letter, read by the Clerk of the House:

“NEW YORK, August 12, 1879.

“HON. J. B. GORDON.

“DEAR SIR:—Will you do me the favor, as a member of the Alumni Association of the State University of Georgia, to present in my name the accompanying portrait (painted by F. B. Carpenter) of Dr. Crawford W. Long, a late member of this association, and the demonstrated discoverer of surgical anæsthesia by the use of sulphuric ether, March 30, 1842; to be placed in the Capitol of the State of Georgia, under their control and supervision.

"I desire to do this in honor of the memory and just fame of this eminent physician and useful citizen, to make his record complete as the discoverer of anaesthesia.

"Providence seems to have intervened to prevent the final settlement of this vexed question until the claims of this modest, unpretending, and gifted man, who really made the discovery, were fully demonstrated by Dr. J. Marion Sims, a native of South Carolina, also a discoverer and a benefactor of humanity scarcely second to Dr. Long himself. His labors in Alabama, which led to the founding of the Woman's Hospital of the State of New York, have also resulted in giving him a world-wide fame as surgeon and investigator.

"It is fitting that these two eminent southern men should both be represented, as they are, in Mr. Carpenter's picture.

"Very respectfully and faithfully your friend,

"HENRI L. STUART."

The words of the gifted senator were eloquent and soul-stirring, and would that the space allotted us permitted of their entire reproduction. We must, however, only select such as seem to us to be the choicest sentences.

"I am here to ask your acceptance of that trust as a feeble and too tardy recognition of that great discoverer's claims to the homage of his countrymen and the gratitude of mankind.

"It so happens that we are indebted mainly to Dr. Marion Sims, also now a resident of New York, a native of South Carolina, himself a benefactor through his discoveries, for the final and almost unquestioned recognition of Dr. Long as the real discoverer of anaesthesia, a science which may be defined, if the medical fraternity present will pardon me, as the science of paralyzing the sensibilities of the human frame to physical suffering, without the destruction of human life—of relieving and almost annihilating the extremest pains to which man is subjected.

"It was thus reserved for one of our own fellow-citizens to make this great discovery, and not only confer a signal triumph upon Georgia, but a blessing upon the human race, which is beyond the power of language to express or the imagination to conceive; an impartial history will abdicate its truest and its holiest mission, if it does not place the name of Crawford W. Long on the same scroll with those of the immortal Jenner, and John Howard, of England, the world-renowned philanthropist, or by the side of the imperishable names of any age.

"This recognition of Dr. Long as the discoverer of anaesthesia, I repeat, has been too long delayed, if it could have been otherwise; and Dr. Long must have so felt it. It is true that other great discoverers have lived and died without witnessing or even anticipating the best results to flow from their discoveries to the world. Franklin, for instance—the far-seeing Franklin—as he sent his little kite flying to meet the clouds and drew thence lightning to the earth and demonstrated its identity with electricity, little dreamed that he held within his grasp a mighty agent which was soon to become subservient to the will of man, to sweep around the globe at man's bidding, outstripping the sun in its flight, and bearing intelligence to man on its wings of fire. But not so with Dr. Long. As he stood, a modest, unpretending physician, in the county of Jackson, on that 30th day of March, in the year of Our Lord, 1842, testing his discovery upon his patient, he must have felt even then, in the very incipency of his discovery, what a priceless boon he was about to confer upon the hu-

man race. And as, with eager eye and throbbing brain, he looked from the result of this experiment over the vast field of human suffering which lay before, he must have lifted his heart in thankfulness to God that He had permitted him to be so great an instrument in the alleviation of physical anguish.

"In the name of truth then, of justice, of science, of humanity and of religion, I commit to your keeping, representatives of Georgia, the claims and fame of our fellow-countryman and humanity's benefactor, Dr. Crawford W. Long."

Senator Gordon was frequently interrupted during the delivery of his address by bursts of applause.

Speaker Bacon then introduced Representative Benjamin C. Yancey, who received the portrait on behalf of the Alumni of the University.

Mr. Yancey reviewed at some length the history of anaesthesia by ether, a summary of which is contained in the following sentences:

"But the historic facts show that Dr. Long's claim antedates Wells's by two years and eight months, and Morton's by four and a half years, and that we are justified, on the basis of truth, to make this public recognition to-day. I am indebted for most of these facts to the pamphlets of Dr. J. Marion Sims and Dr. J. M. Taylor, of Mississippi."

He then paid an elegant compliment to the donor, after which he read a poem written by one of Dr. Long's daughters soon after the death of her father, which seems filled with the spirit of prophecy. One of the verses reads as follows:

Bright shining through the trees the sunbeams play
And gild the ground;
They glimmer on the tombs of those who lay
At rest around,
O'er thee, dear one! no stately column rears
Its lofty head;
Thy life, thy noble life, is all that cheers
Thy humble bed,
Though known to few, thy unrewarded fame
Was truly won,
Some day, thy nation's heart will proudly claim
Her gifted son.

The address of Mr. Yancey was loudly applauded by the cultured audience, and the event was a red-letter occasion in the history of the State, and its proceedings are embalmed in its records.

ELECTRO-THERAPEUTICS AND THE AMERICAN NEUROLOGICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I cannot agree with Drs. Smith and Rockwell in their depreciation of the tone of the discussion at the late meeting of the Neurological Association, because of its admission of great differences of opinion among electro-therapeutists. It seems to me that if any question in science or art is a mooted one—is one about which there are legitimately great differences of opinion, it is far better to have that question freely discussed, and to have the differences of opinion, and the reason for those differences, clearly defined, than it is to throw a silence over honest doubts. Where there are clashing views the truth is not yet established, and it can only be brought fully into the light by careful observation and unrestrained discussion—observation to obtain facts, discussion to criticise them and their bearings. Dr. Smith would seem to believe, however, that the discussion had run upon settled questions, for he uses this strong language: "I have used electricity many times a day

for the past ten years, and have proven to my satisfaction that the pole used, the direction of the current, and the battery employed, are of great importance. This can be demonstrated beyond quibble or doubt by any physician of ordinary intelligence, by trying the different poles on the following diseases," etc. Let us inquire what other men think. Dr. Russell Reynolds ("Lect. Clin. Uses of Electr.," 1874, p. 18,) says: "It may occur to you to ask what current should I use to relieve pain and spasm, the direct or the inverse? All I have to say is, that so far as I have seen it does not make the smallest difference. Theoretically, it should make a very great difference, but practically, so far as my observations extend, it makes none." Benedict, of Vienna, expresses himself in this way: "I have convinced myself day by day that all the so-called facts in regard to the therapeutic efficacy of the different directions of the current are nothing more than theoretical assumptions." (Quoted by Teissier, "De la valeur thérapeut. des courants continus," 1878, p. 40.) Hitzig, Brenner, Chauveau, are equally sceptical in regard to the direction of the current—they are all quoted by the last-named author. De Watteville, in his late work, which is the best extant, writes: "The anodyne and stimulant effects attributed to the positive and negative pole respectively are rarely realized in practice. In most cases it would seem that the curative effects are due more to the general influence of 'the current' properly applied, both as to strength and place, than to any specific action of pole. The same remark, it must be confessed, may frequently be applied to the direction." ("Med. Electricity," 1878, p. 39.) These gentlemen do not hold the same opinion as does Dr. Smith, and yet there can be found members of the profession who have regarded Russell Reynolds, Benedict, Hitzig, Brenner, Chauveau, and De Watteville as *men of ordinary intelligence*. Did your space not forbid it, Mr. Editor, other names could be cited.

I do not think that my position in this matter has been fully understood. I do not pretend to deny that in physiological experiments, in which a nerve or a muscle, or a spinal cord, or a brain, is laid bare, there is a difference in the direction of the current or in the poles; nor do I deny that in certain diseased conditions of nerve and muscle and spinal cord, there will be a difference *diagnostically* between the two poles; but I do deny that for *therapeutic* purposes there has been *proven* to be a difference between the poles or between the directions of the current, except in the case of the face and possibly the uterus. It is possible that these differences may exist therapeutically, but the evidence of them is very fragmentary and inconclusive.

I doubt, however, whether we shall obtain these differences with our present batteries in the limbs and the body, where the nervous and muscular structures, and the viscera, lie comparatively so deep and are covered by such thick structures, often bad conductors, as to necessitate great diffusion of the current. In the face, the facial and trigeminal nerves, and their foramina of exit, are so superficial that they approximate closely to the condition of the bared nerves and muscles of the physiological experiment, and the current can more readily be made to impinge directly upon them.

LONDON CARTER GRAY, M.D.

BROOKLYN, August 18, 1879.

THE AMERICAN PHARMACEUTICAL ASSOCIATION will begin its twenty-seventh annual meeting at Indianapolis, on Tuesday, September 9, 1879, at 3 o'clock P.M.

Obituary.

SAMUEL B. W. MITCHELL, M.D.

DR. MITCHELL died on Saturday, August 16th, at Spring Hill Station, Delaware County, Pennsylvania, in the fifty-second year of his age. He was a Philadelphian by birth, and graduated from the High School and the University of Pennsylvania, and later from the medical department of the University. At the breaking out of the war he served as surgeon in the Eighth Pennsylvania Cavalry, and was at the same time brigade-surgeon. He subsequently was appointed in charge of the cavalry corps hospital at Appomattox, on the James River, and continued in charge for some time. During his administration this hospital is said to have been one of the very largest, neatest, and best managed camp-hospitals in the service. Its efficiency and general thoroughness were attributed to the excellent executive ability of the surgeon in charge. Indeed, this very quality was said to have been one of Dr. Mitchell's most prominent characteristics during his army service. At the close of the war Dr. Mitchell returned to Philadelphia, and has since resided there. He retired from the practice of medicine some years ago. The funeral was solemnized with military honors.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 24 to August 30, 1879.

HEAD, J. F., Lieut.-Colonel and Surgeon. Relieved from duty in Dept. of the East, and assigned to duty as Attending Surgeon and examiner of recruits at Boston, Mass. S. O. 195, A. G. O., August 25, 1879.

CLEMENTS, B. A., Major and Surgeon. Relieved from duty in Dept. of the Platte, and to report in person to Surgeon-General of the Army. S. O. 195, C. S., A. G. O.

HORTON, S. M., Major and Surgeon. Relieved from duty in Dept. of the East, and to report in person to Commanding General, Dept. of the Platte, for assignment to duty. S. O. 195, C. S., A. G. O.

BREWER, JOHN W., Capt. and Asst. Surgeon. Relieved from duty in Dept. of the Platte, to proceed to New York City, and on arrival there, report by letter to the Surgeon-General. S. O. 195, C. S., A. G. O.

TREMAINE, W. S., Capt. and Asst. Surgeon. Relieved from duty in Dept. of the Missouri, to proceed to New York City, and on arrival there, report by letter to the Surgeon-General. S. O. 195, C. S., A. G. O.

VICKERY, R. S., Capt. and Asst. Surgeon. Relieved from duty in Dept. of the East, and to report in person to Commanding-General, Dept. of the Platte, for assignment to duty. S. O. 195, C. S., A. G. O.

KIMBALL, J. P., Capt. and Asst. Surgeon. Relieved from duty in Dept. of the East, and to report in person to Commanding-General, Dept. of the Platte, for assignment to duty. S. O. 195, C. S., A. G. O.

HOFF, J. V. R., 1st Lieut. and Asst. Surgeon. Relieved from duty in Dept. of the Platte, to proceed to New York City, and on arrival there report by letter to the Surgeon-General. S. O. 195, C. S., A. G. O.

ADAIR, GEO. W., 1st. Lieut. and Asst. Surgeon. Upon expiration of his present leave of absence, to

report in person to Commanding-General, Dept. of the East, for assignment to duty. S. O. 195, C. S., A. G. O.

BROWN, P. R., 1st Lieut. and Asst. Surgeon. Relieved from duty in Dept. of Dakota, to proceed to New York City, and on arrival there report by letter to the Surgeon-General. S. O. 195, C. S., A. G. O.

FINLEY, J. A., 1st Lieut. and Asst. Surgeon. Relieved from duty in Dept. of the Missouri, to proceed to Philadelphia, Pa., and on arrival there, report by letter to the Surgeon-General. S. O. 195, C. S., A. G. O.

TAYLOR, B. D., 1st Lieut. and Asst. Surgeon. Relieved from duty in Dept. of Dakota, to proceed to New York City, and on arrival there, report by letter to the Surgeon-General. S. O. 195, C. S., A. G. O.

TURRILL, H. S., 1st Lieut. and Asst. Surgeon. Upon expiration of his present leave of absence, to report in person to the Commanding-General, Dept. of the East, for assignment to duty. S. O. 195, C. S., A. G. O.

KILBOURNE, H. S., 1st. Lieut. and Asst. Surgeon. Relieved from duty in Dept. of the Missouri, to proceed to New York City, and on arrival there, report by letter to the Surgeon-General. S. O. 195, C. S., A. G. O.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending August 30, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Aug. 23, 1879.	4	12	34	6	26	10	0	0
Aug. 30, 1879.	0	16	34	2	16	23	1	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from August 27th to September 2d, inclusive, was 164, and the number of deaths that occurred was 53. The total number of cases for this year to September 3d is 942, and the total number of deaths 270.

NEW ORLEANS.—A number of cases have appeared and a number of deaths have occurred from yellow fever in New Orleans, but strenuous efforts are being made both on the part of the local and the national authorities to stamp out the disease.

HAVANA.—Advices indicate that the disease is still prevalent, although only ninety-five deaths occurred in the week ending August 27th.

THE AMERICAN GYNECOLOGICAL SOCIETY.—The fourth annual meeting of the American Gynecological Society will be held in the city of Baltimore, Md., beginning Wednesday, September 17th, and continuing three days. The annual address will be delivered by Dr. T. G. Thomas, of New York. Mr. George W. Callender, of London, has accepted an invitation to be present at the meeting.

THE AMERICAN ACADEMY OF MEDICINE.—The fourth annual meeting of the American Academy of

Medicine will be held in the rooms of the New York Academy of Medicine, 12 West Thirty-first Street, beginning Tuesday, September 16th, at 3 o'clock p.m. The annual address will be delivered by Dr. Lewis H. Steiner, of Frederick, Md., on "The Preparatory Education most Needed by the Medical Student."

THE NATIONAL BOARD OF HEALTH AND DISINFECTATION.—The Commission of experts appointed by the National Board of Health have reported a circular embodying familiar instructions for disinfection. The committee consisted of Prof. C. F. Chandler, President of the Board of Health, New York City; Prof. G. F. Barker, of the University of Pennsylvania; Prof. Henry Draper, of the University of Maryland; Prof. John Ramsen, of Johns Hopkins University; Dr. S. O. Vander Poel, Health Officer of the Port of New York; and Prof. E. G. Janeway, of the Board of Health of the City of New York. On presenting the report Prof. Chandler, Chairman of the Commission, remarked as follows: "The people must be instructed that no reliance can be placed on disinfectants simply because they smell of chlorine or carbolic acid, or possess the power of permanganate, and that in general proprietary disinfectants with high-sounding names are practically worthless." The following is the report of the Commission:

"Disinfection is the destruction of the poisons of infectious or contagious diseases. Deodorizers are not necessarily disinfectants, and disinfectants do not necessarily have an odor. The disinfectants to be used are: First, roll sulphur for fumigation; second, sulphate of iron (copperas) dissolved in water in the proportion of one and a half pounds to the gallon, for soil, sewers, etc.; third, sulphate of zinc and common salt dissolved together in water in the proportion of four ounces of salt to the gallon, for clothing, bed-linen, etc. The commission exclude carbolic acid for the reasons that it is difficult to secure the proper quality, and it must be used in large quantities to be of service. In using disinfectants in the sick-room, the most available agents are fresh air and cleanliness. The towels, clothing, bed-linen, etc., should, on removal from the patient, and before they are taken from the room, be placed in a pail or tub of zinc solution, boiling hot, if possible. All discharges should either be received in vessels containing copperas solution, or, when this is impracticable, should be immediately covered with copperas solution. All vessels used about the patient should be cleansed with the same solution. Unnecessary furniture, especially that which is stuffed—carpets and hangings—should, when possible, be removed from the room at the outset; otherwise they should remain for subsequent fumigation and treatment. Fumigation with sulphur is the only practicable method of disinfecting the house. For this purpose the rooms to be disinfected must be vacated. Heavy clothing, blankets, bedding, and other articles which cannot be treated with zinc solutions, should be opened and exposed during fumigation as directed below: Close the room as tightly as possible; place the sulphur in iron pans supported on bricks standing in tubs containing a little water; set it on fire by hot coals or with the aid of a spoonful of alcohol, and allow the room to remain closed for twenty-four hours. For a room about ten feet square, at least two pounds of sulphur should be used; for larger rooms proportionately increased quantities. Cellars, yards, stables, gutters, privies, cesspools, water-closets, drains, sewers, etc., should be frequently and liberally treated with copperas solution. The copperas solution is

easily prepared by hanging a basket containing about sixty pounds of the copperas in a barrel of water. It is best to burn articles which have come in contact with persons sick with contagious or infectious diseases. Articles too valuable to be destroyed should be treated as follows: Cotton, linen, flannels, blankets, etc., should be treated with the boiling zinc solution; introduce piece by piece, secure thorough wetting, and boil for at least half an hour. Heavy woollen clothing, silks, furs, stuffed bed-covers, beds and other articles which cannot be treated with the zinc solution, should be hung in the room during fumigation, their surfaces thoroughly exposed, and pockets turned inside out. Afterward they should be hung in the open air, beaten and shaken. Pillows, beds, stuffed mattresses, upholstered furniture, etc., should be cut open, and the contents spread out and thoroughly fumigated. Carpets are best fumigated on the floor, but should afterward be removed to the open air and thoroughly beaten. Corpses should be thoroughly washed with a zinc solution of double strength, and buried at once. Metallic, metal-lined, or air-tight coffins should be used when possible—certainly when the body is to be transported any considerable distance."

PROPOSED NEW MEDICAL SCHOOL IN ENGLAND.—There is to be a new university in Manchester, England, called the Victoria University, which will in some respects supply the educational facilities to Northern England that the London university does for the south. It is proposed that a medical school be attached to it. This proposition, however, is not very warmly received by the existing medical colleges, of which there are nineteen in Great Britain. A protest was formally made against the project, signed by many eminent members of existing medical faculties.

THE PUBLIC HEALTH ASSOCIATION OF BOSTON has been offered \$200,000 by William E. Baker, on condition that half as much more be contributed by other parties.

ALCOHOL IN HOSPITALS.—There is undoubtedly a great deal more alcohol used in hospitals than is necessary, and attention is now being called to the fact by some of those having charge of these institutions in England. The success of the three London hospitals in which its use is entirely prohibited, is leading to considerable discussion on the subject.

MATRIMONY AND INSANITY.—The statistics of the 8,407 patients in the lunatic asylums of Ireland, show that the unmarried were three times as numerous as the married. This would lead one to infer that the domestic life has a tranquillizing effect upon the Celtic mind.

SANITATION IN PHILADELPHIA.—The Board of Health of Philadelphia has compiled a series of practical Rules for the Management of Infants during the hot weather, prepared under direction of the Obstetrical Society. In addition, there are river-excursions and suburban sanitarium, so that the infant mortality is thought to be not so very great in spite of the intensely hot weather.

THE PATHOLOGY OF PSEUDO-HYPERTROPHIC SPINAL PARALYSIS.—In a clinical lecture upon this disease by Dr. W. R. Gowers, with a report of the autopsy, the following conclusions were given from a study of this and other reported cases. The pseudo-hypertrophic paralysis of early life is not a disease of the spinal cord; it is not, as has often been suggested, an infantile spinal atrophy similar to the common forms of progressive muscular atrophy (Cruveilhier's atrophy) of adults, with a modification in the muscle changes due to the peculiar conditions of nutrition in early life. The spinal cord after death shows various ap-

pearances, none of which are characteristic or common to all the cases. Dr. Gowers is inclined to the belief that it is a primary disease of the muscular tissue, "a congenital nutritive and formative weakness of the striated muscle substance." The remarkable relation of the disease to sex; its conspicuously congenital nature in many cases; its character as a disease of development, making its chief progress during growth; its remarkable origin from the mother—i.e., from the ovum only—a condition almost unknown in diseases of the nervous system, are all facts which harmonize better with such a theory than with any other.—*Lancet*.

COLLEGE LECTURE FEES.—All the regular medical colleges in Chicago and Cincinnati have placed the annual lecture fees at \$75, instead of ranging from \$40 to \$55, as heretofore.

ULCER OF THE RECTUM.—Dr. J. J. Fly suggests a very simple remedy for this trouble. It consists in washing the fundament and thoroughly cleansing the rectum with cold water after each evacuation to a point above the ulcer, then stuffing the rectum with dry tannin.—*Med. and Surg. Reporter*.

Original Lectures.

KERATITIS: ITS RELATION TO THE GENERAL CONDITION OF THE PATIENT.

A CLINICAL LECTURE DELIVERED AT THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

By D. B. ST. JOHN ROOSA, M.D.,

PROFESSOR OF OPHTHALMOLOGY.

(Reported for THE MEDICAL RECORD.)

GENTLEMEN:—Here is a boy who is twelve years old. He is very comfortably clothed, has a good color in his cheeks, and looks as if he might have all the conditions favorable to recovery from his eye trouble. His mother tells us he has had bad eyes, "off and on," for five years. Until he was seven years old his eyes were well. The first thing she noticed was that, without apparent cause, his eyes suddenly became bloodshot, that he then had sore eyes for some time, and that when he got well there was left a "speck upon each eye very near the sight of the eye." That means over the pupil and upon the cornea.

This is a very graphic history of a case of inflammation of the cornea which went on to the result which inflammation of the cornea must reach if unchecked, and that is opacity; or, as the mother says, a "speck or spot" upon the cornea. A speck upon the cornea is a serious matter. Suppose you put a speck upon the object glass of your microscope, and then attempt to look through it, you are in the same condition as the patient who has a speck upon his cornea. It is impossible to get distinct vision through the obscure medium. Sometimes short-sightedness results from such a straining of the eye. Stand the boy before a window that has been coated with brown paint, in which there has been left here and there a fissure, and tell him to look through it upon the landscape beyond, he will strain his eyes to do so, but he will not get clear vision at any point, unless the fissures in the paint are large and clear. So it is with disease of the cornea; there is not only a blemish upon the cornea, but much more, and that is the effect produced upon the eye by the overstraining to which it is subjected by reason of the resistance offered to clear vision by the speck of opacity. Such a condition of the cornea renders it impossible for the female child to learn to sew without straining the eye, or for any child to read without the same effect, and the eye is constantly liable to new attacks of inflammation from overstraining. It would be interesting to know what gave rise to his eye trouble at the age of seven. Perhaps we cannot reach the answer to such a question, but I know, from the straightforward history of the case, that the disease at that time was something from which he did not get thoroughly well. If these inflammations are allowed to go on and involve the structures beneath the epithelium, the anterior elastic layer, and the true structure of the cornea, they will probably not get well without an abnormal physical condition. So this boy was left with a provocative to another attack of inflammation. It is also interesting to know what was the state of his general health at that time, for I have come to consider disease of the cornea as an index to the general condition of the patient. His mother says that he had the measles a short time before his eyes became sore, but that, appar-

ently, he made a complete recovery from that disease, so much so that he ate well, slept well, and was running about with the other children when the eye trouble developed itself. Judging from the evidence of the mother, and it seems to be trustworthy, the boy was in fair health and was being fed properly when this inflammation was developed, so there may have been some local mechanical cause which gave rise to the disease that has produced this change in the cornea. When asked what was done for the eyes when the inflammation first appeared, the mother says that the family physician treated it, and according to the proper rules, he did not put on a poultice, and from her account we cannot ascribe any fault to him. The case not progressing favorably, he recommended that the boy be taken to an eye infirmary, which was a very proper thing for him to do, for the people have a right to expect that he would there receive the best treatment that could be afforded. It seems, therefore, that when this boy was in a fair condition of health he was attacked with an inflammation of the eye that terminated with spots upon the cornea. This is a rather sad story, for we cannot find any condition which retarded recovery, nor any well-defined cause for the outbreak of the disease of the eyes. The case seems to come into that category in which the result is that complete recovery does not take place even under the very best of treatment. There is probably an inherent vice in the constitution of our patient, or something in his surroundings which we cannot at present find out. As illustrating this point, I remember a case in which the patient suffered from recurrent attacks of keratitis, and I was unable at first to detect any cause which I could regard as affording sufficient explanation of the recurrence. Finally, I learned that he was exposed to the acrid fumes of ammonia from a stable which opened almost into his bed-room. Taking the cue from what I saw in some students of veterinary medicine, who had keratitis, I suspected that the ammonia fumes might be the cause of the repeated attacks of inflammation in my patient. Accordingly, I had him removed from the exposure to the emanations from the stable, and, sure enough, he made a rapid and permanent recovery. There may be some such influence at work in this case, of which at present we know nothing. As yet we have found but very little in explanation of his present condition.

I will now describe his eyes. He has inflammation of the lashes, blepharitis; he has crusts at the roots of the lashes, and there are two spots upon his left cornea; there are blood-vessels running up to the lower spot, and the lower part of the ocular conjunctiva is redder than it should be.

BLEPHARITIS: ITS RELATION TO STRAIN OF ACCOMMODATION.

He has, then, blepharitis, keratitis, and that incurable condition, opacity of the cornea. What is the cause of his blepharitis? I believe I was the first to show that blepharitis depends very largely upon strain of the accommodation. I do not say that this boy's blepharitis does so entirely, but I do say that with opacity of the cornea, nearly over the pupil, he has conditions which must cause a strain of the accommodation, and I doubt not but that his blepharitis would disappear if I could remove the spots from the cornea. This blepharitis can be relieved, however—I will not say cured—because there exists the occasion for the constant lighting up of it in the strain necessary to look through an obscure medium. By simply keeping these crusts away, and putting a small quantity of grease along the borders of the eyelids,

his blepharitis will be very much relieved. Am I minute in the description and in my remarks upon this case? It is because I wish you to be minute, and to take into consideration every change, however slight, from the normal condition of the eye and its appendages. I wish you to notice the *character* of the opacities of the cornea which you see, and determine whether they are recent or old. If the opacity is old, there is no skill sufficient to remove it; but if it is recent, irritants and an improvement of the general condition of the patient may stimulate the absorbents sufficiently to cause it to disappear altogether.

In the right eye there is something much more recent than in the left. The entire eye is watery. There are also crusts at the roots of the lashes, the eyelids are red, and there are opacities upon the cornea, but they are soft. I know that these opacities are recent. I know that there is a process going on now in this eye, and that that process is an inflammatory one in the tissues of the cornea. It is an ulcer really, and fortunately it is a little below the pupil. But the boy's eyes are irremediably damaged for life. He will never have sound eyes, but he may be in a very much better condition than he is at the present time. The ulcer in the right eye may heal, and perhaps by the time he has reached twenty-one years of age the large spots upon the cornea will have disappeared. I suspect such a result, for the reason that people come to my office constantly and complain of being short-sighted, of being unable to see things well at a distance, and of not seeing objects thoroughly well even when near them. When they are brought before an ordinarily bright light you cannot see any change whatever in the cornea, but when the cornea is exposed to a strong light you can at once see that it is irregular in shape, and that there are very thin opacities. Then you know that it was once inflamed, and, upon further inquiry, you will be told that there was at one time a marked opacity of the cornea. The opacity, however, has nearly disappeared, and there remains little more than an irregular curvature at that point. Now, the patient, instead of looking through an opaque medium, is looking through a medium which does not have the requisite curvature for the proper collection of the rays of light; and there is nothing which you can do to improve the condition. So I suspect that this case may go on and get well of everything except an irregularity in the shape of the cornea.

We now have the history and the diagnosis of the case, but we have not gained much knowledge regarding its etiology, and nothing has been said of the treatment.

I have stated something with reference to *prognosis*, and I may add that it is good, so far as restoration of the eye from painful and unpleasant symptoms is concerned, but for perfect recovery the prognosis is bad.

TREATMENT.

What is the present general condition of the patient? Let us examine and see if that can be improved. He does not attend school, so that unfavorable surroundings, for eyes in the condition in which his are, do not exist. What does he do during the day? The mother tells us that he remains indoors most of the time, lies upon the sofa, etc. Doubtless, here is a circumstance which must be corrected. Disease of the cornea, as I have already said, a tissue which has no blood-vessels of its own, furnishes an index to the general health. Corneal disease, unless it be of purely mechanical origin, such as comes from

lodgment of foreign bodies in the epithelium or in the deeper structures, is an evidence of a bad condition of the general health. Something is wrong. I have not yet found what it is in this boy's case, but there is malnutrition present from some cause. At all events, we will correct his habit of spending so much of his time in the house. He must go out. But suppose he goes out in the streets of New York, which our Police Commissioners take such remarkable care of, the dust will fill his eyes, and therefore they need protection. Hence we will protect them with blue glasses. Why blue? Because they cut off the rays of light which are most unpleasant to the eye. The glasses should have a shape which will cover the front of the eye; they should have a shell-like surface, with the concavity toward the eyes. I do not mean goggles. There are but few circumstances under which goggles should be worn. They heat the eyes. Furnished with a pair of glasses, the boy should be sent out into the open air; to Central Park, to Madison Park, to Washington Park, or to any park near which he may live. Send him out into the open air, and at the same time he should be occupied with some sort of amusement which will give him moderate physical and mental exercise. As a local application he is at present using sulphate of atropia, and that treatment is very proper. It is an anodyne application, and, besides, it enlarges the pupil; but in this there is some disadvantage. I wish for such cases as this we had an agent which was an anodyne, and at the same time allowed the pupil to remain unchanged. He has no iritis, hence there is no special indication for an agent which dilates the pupil. But the blue glasses will obviate a part of that disadvantage. There is another indication in the case. The eyelids must be kept clean. In the first place, all these crusts should be removed, and that can be best done perhaps by bathing with water which contains a small quantity of bicarbonate of soda. When the crusts have been thoroughly removed, the edges of the lids may be greased with a little vaseline, cosmoline, cold cream, glycerine, sweet-oil, simple cerate, or mutton-tallow without fat. When these indications are met, we have done all that we can do at present, locally. His diet should be nutritious, his sleeping-room should be so situated that an abundance of fresh air can gain admission, and in order to get his eyes well, indeed, he must be treated as though he had consumption. He should receive a bath at least three times a week, and an effort will be made to place him in a proper hygienic condition, and perhaps improvement will result. As a result of these ulcers of the cornea we may have vascular cornea, we may have the formation of an abscess in the cornea; little vesicles also occur upon the cornea—phlyctenular keratitis. This catalogue embraces nearly all the affections of the cornea.

ULCER OF THE CORNEA—AFFECTION OF THE EAR—DANGER OF ATROPIA-POISONING.

Here is another case of disease of the cornea. This baby is twenty months old. There is a white spot over the centre of this little girl's pupil. It is soft-looking, and I therefore know that it is recent. The child has nasal catarrh. It was weaned when six months old, and it is now just cutting its eye-teeth. The mother says it is being fed with whatever there is upon the table; that it receives a little tea and coffee, and that it is allowed to suck pieces of meat, all of which is wrong. Do not allow it among your patients, gentlemen. If the good Lord had wished us to eat meat at the age of twenty months, he would have given us a full set of teeth ready for use at that time.

Dr. Leaming, of this city, whom you should all know, has for some years had charge of an asylum in which large numbers of children are received and cared for, and he does not allow one of them to have anything except milk, and substances which can be dissolved in milk, until they are seven years of age. I think your professor of *materia medica* is equally emphatic upon this question, and now your professor of ophthalmology comes to you and beseeches of you to use all possible influence in the direction of having children reared upon milk alone. Not upon tea, not upon coffee, not upon meat, not upon sweet cake and puddings, but upon milk. Every physician will, under rare circumstances, prescribe beef-juice for infants, very much as brandy is prescribed upon rare occasions for small children, and I shall not quarrel with them upon that point. But I have a decided opinion that, under ordinary circumstances, no child should have anything except milk and farinaceous food until it has been provided with teeth with which to prepare other articles of diet for the stomach. Follow nature in your practice in ophthalmic as well as in every other kind of disease. I will engage, if this mother, who is anxious for her child, will listen to what I say about feeding it hereafter with milk, barley, farina, corn-starch, hominy, with perhaps a small quantity of sugar, that the teething will be easier, the bowels will be more regular, and diseases of the cornea will be less liable to occur. The ear is also in trouble. The child has then an ulcer of the cornea, and also an affection of the ear. The baby is cross because it is unhappy. As we look at the ear we see that there is pus in the auditory canal, and there is eczema behind the ear. What shall we do for this patient? We will do something for the local condition; for the eye we will order sulphate of atropia, one grain to four ounces of water. Of this a few drops should be put into the eye three times a day. The eye should also be bathed and kept clean with lukewarm water. The ear should be kept clean by syringing the auditory canal with tepid water, and a small quantity of vaseline should be used to overcome the irritation of this roughened surface behind the ear. The bowels are regular. We will also direct that small doses of iron be administered, and will tell the mother to take the baby out into the open air every day. We cannot adjust spectacles to the eyes of so young a child as this, but it may wear a shade. There is a belief, and the opinion was advanced by a reputable man, that errors of refraction cause chorea. One of the disciples, not the author himself of this doctrine—for the disciples sometimes regard themselves as wiser than the master—recommended that a child so early in life as three years should wear spectacles. You can imagine the result of the recommendation.

This child looks well clothed—too well clothed to appear in such a clinic as this—a fact which will be closely scrutinized and corrected if necessary, and it doubtless can have very many of the comforts of life.

You can now see what my lecture upon keratitis gets to be; it becomes a lecture upon *general hygiene*. For I must again state my belief that keratitis, idiopathic, not excited by mechanical injury or surgical procedure, is a constitutional affection, and requires a most careful attention to the patient's general health. It requires the attention of a general practitioner in the largest sense of the word.

DANGER OF ATROPIA-POISONING.

I suppose you are sometimes tempted to ask, Is there no danger of atropia-poisoning from the use of the agent in the eyes of such young children? We do

sometimes meet with cases in which such symptoms are developed, but the dose is so small, in a solution of the strength which we have recommended, that there is but little danger of developing *serious* symptoms. If unpleasant results are to be manifested, it is usually very soon after the administration of the remedy, and that result should have the effect of diminishing the dose. I have known children to get as red as a lobster within a few minutes after the application of a few drops of a two-grain solution to the conjunctiva, but such are exceptional cases, and, usually, you can use atropia for weeks in succession without producing unpleasant consequences. You can produce a kind of chronic conjunctivitis by using atropia too long without occasional intermissions. Therefore, you should occasionally omit the medicine for the purpose of determining whether or not it may not be keeping up the irritation. The late Dr. Ely, of Rochester, in this State, had a very good habit when he came to a case that had been under treatment for some time, of stopping everything in order that he might know how the patient was without treatment. He was like a man taking soundings upon shipboard; and it is very well sometimes, particularly after having used drugs for a considerable length of time, to stop the use of those drugs and see where your patient is. So it is in the use of atropia; you must have your suspicions aroused, after it has been used for a long time and the eye seems to be more irritable than at first, that the atropia may be the agent which produces the irritation. You will occasionally be obliged to stop the use of the remedy on account of such a result.

Original Communications.

ADENOID GROWTHS IN THE VAULT OF THE PHARYNX—THEIR REMOVAL BY THE GALVANO-CAUTERY.

By J. O. ROE, M.D.,

ROCHESTER, N. Y.

FELLOW OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

(Read before the Central New York Medical Association, 1879.)

In the vault of the pharynx, just below the junction of the vomer with the sphenoid, is found an aggregation of glandular tissue consisting mostly of the stroma of the mucous membrane which has become more strongly developed, and containing in its meshes of network a large supply of lymphoid cells.

This tissue is ordinarily spread out somewhat thinly over the vault, and extends over the pharyngeal projection of the Eustachian tubes, and into the fosse of Rosenmüller. Often, however, it is less flattened out, forming a sort of cushion in appearance. In some cases it is concentrated or accumulated into a more rounded mass, and is then called, from its histological composition, the "pharyngeal tonsil." At other times it is laid in longitudinal ridges or combs of various lengths, running antero-posteriorly or obliquely, and separated by fissures or lacunae of varying depths. It is covered with ciliated epithelium, and the line of demarcation between it and the surrounding tissue can usually be distinctly traced.

Henle speaks of this tissue as conglomerated glandular substance. Luschka and His describe it as adenoid, while Kölliker considers it as an increased development of the cystogenetic layer of the mucous mem-

brane; that is, resembling the lymphatic gland-tissue, with extensive distribution of lymphoid cells in the interspaces.

The existence of this glandular tissue in the vault of the pharynx was recognized long before the introduction of the rhinoscope into practical medicine; but so little was known concerning its nature and diseases that mention of it was seldom made in medical literature. When observed, which was usually during anatomical dissections, it was described as simply "a chain of glands extending across the pharynx from one Eustachian tube to the other." It did not, however, escape the attention of the celebrated William Hueter, who exhibited in his museum careful dissections of this tissue, both in its normal and pathological condition.*

Horace Green briefly mentions these adenoid growths in his work on "Follicular Disease of the Pharyngo-Laryngeal Membrane;" Czermak speaks of them as "cock's-comb protuberances;" Türck refers to them as "vegetations;" while Semeleder describes two cases of polypi from the roof, which Meyer considers must have belonged to this category.

The first recorded attempt at examination of these growths by means of the rhinoscopic mirror was made by Voltolini in 1865.† He observed comb-like, club-shaped, or berry-shaped formations in this region, which he described as polypoid vegetations of the mucous membrane; and in 1868 a very admirable and elaborate description of the microscopic anatomy of this tissue was given by Prof. Luschka.‡

But little practical attention, however, was directed to the disease of this tissue until Dr. William Meyer, of Copenhagen, gave the results of a careful study of this subject in an elaborate article on "Adenoid Vegetation of the Naso-Pharyngeal Cavity."§ He says: "These vegetations are found to consist of adenoid tissue, and are therefore morbid growths of the closed glandular structure of the pharynx. They vary in form and consistency, sometimes being solid and firm, and at others soft, highly vascular, and prone to bleed."

The diseases most common to the gland-tissue in the vault of the pharynx are those of a chronic inflammatory or catarrhal nature, from exposure to various irritating causes to which it is constantly subjected, leading to hypertrophy and adenomatous growths. In fact, the cause, history, and progress of the affections of this tissue are those of ordinary post-nasal catarrh; and a great number of the cases of so-called chronic post-nasal catarrh, commonly considered incurable, will be found to be due to localized disease of this tissue; and when this tissue is removed, all symptoms of a general catarrh will readily disappear.

These adenomatous neoplasms may be divided, according to the nature or manner of attachment, into sessile and pedunculated. In the early stages of a growth it is often difficult to determine which of the two forms it will assume; but the sessile is by far of the more frequent occurrence. These growths vary in size from a small projection to one sufficiently large to completely fill the nasal pharynx,|| and, as sometimes seen, to project below the palatine border; moreover,

owing to their vascularity, they appear at times much larger than at others. Their frequent association with enlarged granulations in the upper part of the pharynx has led many* to believe in the existence of a connection between the two. Such, anatomically speaking, is not the case. The granulations consist in hypertrophy of the solitary glands; while in the adenoid enlargement, all the elements of the mucous membrane are associated in the hyperplastic action.

The buccal pharynx is composed of connective tissue, while in the nasal pharynx the adenoid tissue largely predominates, and the mucous membrane is much thicker and more vascular.

Etiology.—The causes to which these growths are most frequently attributed, are coryza and exposure to cold and damp. Owing to the readiness of this adenoid tissue to absorb moisture on exposure to humid atmospheres, more or less stasis is produced, exudation takes place from the turgid vessels into the substance of the tissue, and becoming organized, results in a permanent enlargement. Adenoid growths are found most frequently in persons leading an indoor life, owing to the debility of the local parts from lack of air and exercise, and the congestion produced by sudden change from hot rooms to cold or damp air.

The cause for the greater frequency in children lies in the lymphatic temperament, and the anatomico-physiological connection, through the lymph channels, between the naso-pharyngeal region and the cervical lymphatics. The larger size of the channels in children also explains the frequent occurrence of enlarged glands of the neck in those suffering from nasal catarrh. Often an inherited serofulous taint predisposes to these growths, and they are very frequently associated with cleft palate, owing to the direct exposure of this region to various irritating causes.

The age at which these growths are most frequently found is during childhood and youth, but they are also found in many cases of adults of both sexes; although rarely to the extent of filling the cavity of the nasal pharynx, as frequently found in children. They are not known, however, to occur in advanced life.

Symptoms.—In the course of the growth of these tumors, the first function materially interfered with is the free normal respiration; and as the growth increases so as to fill more and more completely the cavity of the nasal pharynx, all the functions depending on a normal condition of these parts—as the respiration, phonation, smell, and hearing become correspondingly impaired.

In children, the growths are usually much larger than in adults, proportionate to the size of the nasal cavity, consequently with them nasal respiration is more seriously interfered with. In children, the first and most prominent symptom is the constantly open mouth, which occasions later on the drawing down of its corners; the lengthening of the line of the nasal wing; a stretched and wrinkled appearance of the skin of the face; a flattened or compressed appearance of the nose from arrested development, and, together with a frequently sallow complexion, gives to the child a peculiar indolent or vacant expression. Sometimes a drawing down of the inner canthus of the eye, so strongly as to give to the face a strange Chinese appearance, as has been observed by Michel; † "deafness and a peculiar deadness to the articulation of certain consonants, as *m* being pronounced like *b*, and *n*

† Diseases of the Nasal Cavity and the Vault of the Pharynx. Cologne, 1876. English translation by Shurley and Yemas, p. 82.

like *d*; a peculiar way of pouting or twisting their lips, toying with them as it were,"* are also striking characteristics.

In *adults*, these symptoms are not usually so well marked, for it is seldom that the size of the growth is sufficient to completely obstruct nasal respiration. They are very clearly described by Dr. Andrew Clark,† as "discomfort, aching, or pain in the neighborhood of the soft palate and posterior nares; tingling, or sense of fullness about the root of the nose, frontal headache, a mawkish or fœtid taste in the back of the mouth, a thick mucus, purulent, or cheesy secretion discharged at intervals, chiefly through the mouth, by means of snorting nasal inspirations, followed by hawking, slight perversion of taste and smell, alterations of voice, sometimes temporary deafness from obstruction of one or both Eustachian tubes, and an abundant secretion of wax in the external ear."

We will now consider the relation of these growths to these important functions. The injurious results to both organs by the substitution of buccal respiration for nasal respiration is at once apparent. During the passage of air through the tortuous nasal passages it is subjected to two important physical changes:

1st. It becomes elevated in temperature.

2d. Laden with moisture by the evaporation going on from the extensive surface.

The effect of buccal respiration on the pharynx is often quite marked. The cold air strikes the pharynx, heat and moisture are abstracted, and the effect is to excite secretion and induce irritation, resulting in granular pharyngitis. In many cases, however, this pharyngitis is produced by other causes, which tend in turn to induce these adenoid growths.

It has been pointed out by Stoerck that the mucous membrane becomes œdematous after obstruction of nasal respiration for a length of time, and the mucous follicles undergo colloid degeneration. The degeneration, however, is the result of the hypertrophy as a primary cause, and frequently results in sufficient infiltration, particularly over the inferior turbinated bones, to require active treatment and often instrumental removal. The same degeneration may extend to the terminal fibres of the olfactory nerve in the pituitary membrane, and thus enfeeble or destroy the *sense of smell*. Occlusion of the nares will also produce the same result by preventing the inspiration or entrance of the odoriferous particles.

With the enfeebling of the sense of smell comes the impairment of an important element in the *sense of taste*. The sense of taste proper is only capable of distinguishing the four elementary properties of sapid substances, as sweet, sour, saline, and bitter, while the perception of all the aromatic flavors depends on the sense of smell. The lack of this element in the taste is often observed in those whose smell is destroyed, and the experiment can readily be made by tasting a choice brand of wine with the nostrils closed, when it will seem flat and insipid.

The most important office of the passage of air through the nose before it enters the lungs, is the arresting or filtration, so to speak, of foreign substances, as dust, spores, etc., from the air; the necessity of which is shown by the experiments of Tyndall, Pasteur, and others. Smith and Davis‡ estimate that there are ordinarily contained in the air we breathe during ten hours, 37½ millions of spores. A microscopic examination of the nasal mucus and the air

found in a crowded, illy-ventilated room, will at once convince one of the importance of nasal respiration in protecting the pulmonary organs; and aptly illustrates the old proverb, "Shut your mouth and preserve your life."

The cutting off of nasal respiration exerts a marked influence in arresting the *development of children*. The first and most serious impediment is its interference in nursing, for as soon as the child closes its mouth on taking the breast it is at once unable to breathe, and has to remove its mouth to take breath. The transitory symptoms of false croup, or laryngitis stridulus, occurring in the early part of the night, to which many children are subject, are often due to this cause. On lying down, while sleeping, the tongue dropping back closes against the soft palate, and, acting as a valve, produces marked stridulous breathing, and should the mouth become closed, suffocation is at once produced, and the child starts up with a cry and spasmodic gasping for breath. In this manner can be explained the restlessness and spasmodic starting in sleep in many children, the cause of which is so often looked for in some nervous derangement. Several cases of this kind have come under my observation, and on the removal of the obstruction the trouble entirely disappeared. I can now recall a very marked case of this kind which occurred several years ago. The patient was seen by several noted physicians, but none succeeded in giving any relief, as all their attention was directed to the nervous system.

The deformity known as *chicken- or pigeon-breast* is often produced by these obstructions, concerning the cause of which the general examination or history will give no clue. In the growth of adenoid tumors there is a transition stage, before the nasal respiration is completely cut off and buccal respiration established, when a deficient amount of air enters the lungs, and by the action of the inspiratory muscles tends to collapse the chest, the pliable ribs giving way to the external pressure. Dupuytren and Roberts attributed this deformity to enlarged tonsils, entirely overlooking the fact that they might be the result of these growths.

Open and clear nasal passages are of the utmost importance in the function of speech, particularly in the pronunciation of the nasal consonants *m* and *n*, which are pronounced *b* and *d* when the posterior nasal opening is occluded. The manner in which this substitution takes place is explained by Loewenberg,* as follows: In the pronunciation of *m*, the air is emitted through the nose, while the buccal cavity is closed in front by the compression of the lips one against the other, the posterior nasal opening and larynx remaining at the same time open. The same configuration of the buccal cavity is necessary for the pronunciation of *b*, except that the soft palate is raised, intercepting the passage through the nose, and the current of air fills the mouth, pressing against the lips, forcibly separating them.

Thus we see that when the posterior nasal passage is closed by the pathological obstruction, the tumor, on attempting to articulate *m*, it becomes impossible. The expired current of air is compelled to escape by the mouth, and *b* is pronounced. The process is exactly the same in the substitution of *d* for *n*, except that the anterior closure of the buccal cavity is made by the tongue, the tip of which is brought in contact with the superior incisors and alveolar process when *n* is pronounced, the current of air being compelled to

† *London Hosp. Reports*, Vol. I.; Spencer Watson, *Diseases of the Nose*, p. 65.

‡ *Loewenberg*: loc. cit., p. 21.

* *Loc. cit.*, p. 27.

pass through the open posterior nasal passage; while in the pronunciation of *d*, the tongue is forcibly separated from the teeth and alveolar process. Thus the labial and lingual resonants, *m* and *n*, are replaced by the labial and lingual explosives, *b* and *d*, so that moon is pronounced *bood*; common, *cohbod*; and nose, *loze* or *doze*. The peculiar nasal twang is also so characteristic as to be readily distinguished when heard.

The influence on the voice in singing is often marked. It muffles the voice and interferes with the emission of high notes by preventing the elevation of the soft palate. Cases are recorded when, after an operation, the voice rose a tone and a half.

Effect on the ear.—Pharyngeal adenoid tumors are nearly always associated with chronic inflammation—as pharyngitis, rhinitis, sometimes hypertrophy of tonsils, and, most frequently of all, with Eustachian catarrh. Meyer found, in 175 cases which came under his observation, that in 130 there were auricular complications.

The ear may be affected by the tumor in three ways:

1st. By the propagation of acute or chronic inflammation through the Eustachian tube to the middle ear.

2d. By the pressing of the tumor against the orifice of the tube, mechanically closing it, and by thus preventing the entrance of air, the membrana tympani becomes collapsed, and in cases of Eustachian catarrh prevents escape of the mucus secreted, causing supuration and perforation of the drum-head.

3d. By mechanically exhausting the middle ear of air during deglutition, in cases where there is complete obstruction of the nasal openings.

The influence of nasal respiration on the ear is illustrated by Mr. George Catlin, in his history of "The North American Indians." Among two millions Indians, he found not one who was deaf or breathed through the mouth, except three or four deaf-mutes; and in the memory of the chiefs of 150 tribes, not one case of deafness could be remembered to have occurred. This is explained by the mother always closing the mouth of the child whenever it attempted to breathe through it.

Diagnosis.—The diagnosis of these growths is ordinarily quite easy. In many cases the symptoms are sufficient to afford very conclusive evidence of their existence, but it is only by a rhinoscopic or digital examination that a positive diagnosis can be made. Michel* states that he is ordinarily able to recognize them through the nostrils; but it has not been my good fortune to be able to do so only in very exceptional instances. Whether Michel's success was due to the large-sized nasal openings in the people of Cologne I cannot say.

In the normal vault the only projection to be seen by the rhinoscopic mirror is the pharyngeal orifice of the Eustachian tube, consequently any considerable elevation above the normally smooth walls is at once to be considered an abnormal growth. By means of the rhinoscopic mirror we are able to determine their exact location, size, color, nature of secretion, if multiple or single, pedunculated or sessile. When sessile they usually form one rounded mass, with numerous small openings, which lead to a general cavity with communicating recesses.† From each opening will be seen exuding a thick viscid mucus, ordinarily quite clear, but sometimes discolored and mixed with

pus or blood. Often this material will dry on the surface, forming a sort of cap, which, when removed, will represent the outline or configuration of the surface of the tumor. When pedunculated they are usually multiple, and hang down from the vault in clusters, or berry-shaped excrescences. They are usually of a bright red color, but sometimes have the appearance of an hypertrophied tonsil. Their presence will sometimes be indicated by their interfering with the introduction of the Eustachian catheter.

In many cases a digital examination, as proposed by Meyer, is necessary to determine the consistency, if firm or flaccid, the exact attachment, and to distinguish in doubtful cases if the enlargement is a fleshy growth or an osseous projection or tumor. After a digital examination there is usually more or less bleeding, and so great is their vascularity that, as observed by Dr. Cohen,* slight hemorrhage is often produced by the projection of a jet of water against them from the posterior nasal syringe. Meyer likens the sensation perceived by the finger to a bunch of earth-worms. A like sensation is, however, often produced by the constriction upon the finger of the muscles of these parts.

In early childhood the symptoms which these growths produce may be mistaken for those produced by coryza and hypertrophy of the tonsils, and in adults with chronic naso-pharyngeal catarrh, hypertrophy of the tonsils, and nasal and naso-pharyngeal polypi. In each of these cases a careful examination will reveal the exact nature of the difficulty.

The *prognosis* is always favorable as far as removal is concerned, and the affections which they have produced in other organs are usually much more amenable to treatment than when produced by other causes.

Treatment.—The treatment of these growths is divided into local and general. The association of these growths with the lymphatic temperament is so frequent that more or less general treatment is usually called for. It should consist in good hygiene, plenty of exercise in the open air, cold sponge or sea baths, and cod-liver oil, bitters, iron, and iodine preparations if required. All irritants, as too hot or cold food, alcoholic liquors, tobacco, bad air, and excessive use of the voice, should be avoided. In cases where there is no diathesis to combat, only the injuries done by the presence of the tumor have to be counteracted.

The *local* means employed are ablation and cauterization. The method usually employed for ablation is by crushing, by means of forceps with strong blades curved at a proper angle to pass up behind the palate; the curette, as used by Loewenberg, consisting of a spoon-shaped blade with cutting-edge, and attached to a handle by means of a slender shank; the *éraseur*, as recommended by Maisonneuve and Wilde; and the cutting forceps, as devised and used by Fauvel, Stoerck, and Cohen. These cutting-forceps are often very convenient as an expeditious means of removing small growths. There is but little danger of injury resulting from their use, as whatever adventitious tissue is found in the vault is legitimate prey. Meyer has recommended an annular knife to be passed through the nostril, by which he scrapes off the tumors. This, however, is only applicable in cases of large vegetations.

Since the introduction of the galvano-cautery into the treatment of these growths by Voltolini in 1867, it has been fast superseding all forms of caustic applications and operative procedures. Its advantages over all other methods are very great, due to the

* Loc. cit., p. 83.

† Clark, London Hosp. Rev., Vol. 1.

* Loc. cit., p. 259.

rapidity and effectiveness of its action, and the avoidance thereby of hemorrhage, which in the cutting operations is frequently very profuse and exceedingly troublesome, owing to the great vascularity of the parts.

The cautery can be used in two ways, according to the variety of the growths. For those which are pedunculated, the platinum wire loop passed through the nostril and around the tumor is best adapted; and for the sessile variety, the curved electrode devised by Lincoln,* which is passed up behind the palate, in the end of which is a coil or disc of platinum protected from injuring the surrounding parts by a shield, and is made to fit Lieter's handle. I have recently had an electrode made with the stem coated with asbestos, which protects the parts entirely in case the stem becomes heated.

In some cases a simple hook for holding the palate is all that is required; but in cases of muscular and rigid palates, where gagging is easily induced, the most reliable retractor I have found to be two soft tapes passed through the nostrils and out of the mouth and tied over the upper lip in front, as suggested by Dr. Cohen; or a rubber cord used in a similar manner, as proposed by Dr. Walcs. By thus drawing the soft palate forcibly forward the shield can to advantage be dispensed with, and by means of the rhinoscopic mirror the entire operation can be performed under sight; and it can readily be seen when the entire destruction of the growth is accomplished. Ordinarily, the use of anaesthetics is unnecessary, as the pain attending the operation is not great; but in some cases of nervous patients, or very irritable throats, they are advisable and occasionally indispensable. The battery which I use is Dawson's, manufactured by Geo. Tiemann & Co., which, with Lieter's handle, leaves but little to be desired for a perfect cautery apparatus.

To illustrate the preceding remarks, I will select a few cases from my note-book as we meet them in practice.

CASE I.—Miss H. D.—, *et.* 22 years. Referred to me Feb. 16, 1875; suffering from trouble in her throat, and deafness. She complained of stoppage of the nares, with a sensation of fulness in the back part of the nares just above the soft palate, and of a thick mucous discharge from posterior nares. Her voice had a muffled and indistinct expression. She also complained of an itching sensation in external auditory meatus, and there was an abundant secretion of wax in the ears. On rhinoscopic examination I found a large growth of adenoid tissue almost filling the vault, pressing on the pharyngeal opening of the Eustachian tube, and hanging down behind the velum, which had quite a polypoid appearance. Not having a galvano-cautery at hand at the time, I removed it with a pair of sharp-edged scoop-forceps, such as are used by Meyer. Considerable bleeding occurred at the removal, but it was readily controlled by perchloride of iron. She continued under treatment for a short time for the deafness, and also some naso-pharyngeal catarrh with which the growth was associated. The latter trouble was removed by local treatment, the closed Eustachian tubes were opened by the introduction of the Eustachian catheter, and her hearing was left but slightly impaired.

June 3, 1877.—She returned with a reappearance of the adenoid growth to nearly its former size, and an increase in her deafness. I then applied the galvano-cautery. One application was sufficient to destroy the growth entirely; and since her voice has

been good, hearing greatly improved, and there has been no tendency to a return of the growth.

CASE II.—Miss S. J.—, *et.* 21 years. Had suffered from more or less throat trouble for the previous seven years. Had also had a great deal of cough and expectoration which proceeded from a bronchial catarrh in right lung. The trouble in throat consisted in an irritation and tickling, with stoppage and sensation of fulness in posterior nares, just above the soft palate. There was also considerable tenacious discharge from posterior nares, obliging her to hawk and cough in order to keep her throat clear. She had also considerable frontal headache. On rhinoscopic examination there was seen a mass of adenoid tissue obstructing the passage; the growths being thrown into folds, giving it a cock's-comb appearance. A profuse tenacious discharge was poured from the openings of the lacunæ of the glands, which were very sensitive and bled on the slightest touch. Her singing-voice, which was before very clear and strong, had become flat and the compass restricted. Removal of this diseased tissue by the galvano-cautery was advised and readily assented to. The first application of the cautery did not result in the complete removal; accordingly, after an interval of about ten days, it was repeated with entire success. Local applications were made to the surrounding congestion, and the slight thickening which the tumors had caused; inhalations and appropriate internal remedies for the bronchial catarrh were given; and she is now enjoying excellent health.

CASE III.—Miss E. W.—, *et.* 23 years. She was slender, delicate, and of a scrofulous diathesis, although quite well until the previous September. Came under my care Dec. 15, 1876. She had been greatly annoyed for about three months by a very profuse discharge of a thick tenacious mucus from the posterior nares, which she was unable to expectorate or clear from her throat. The only manner by which she could dispose of it was by swallowing, which would bring on attacks of sick-headache and nausea every few days. The discharge was aggravated by damp weather or colds, increasing accordingly the frequency of the attacks of nausea, which were very exhausting. She lost flesh and strength quite rapidly. Had a constant dull frontal headache, also an irritation in throat which excited cough, some obstruction to nasal respiration, and difficulty in her enunciation. On rhinoscopic examination, the vault was found filled with hypertrophied glandular tissue, from which the mucus was exuding. Digital examination gave to the finger the peculiar sensation of a bunch of earth-worms, as described by Meyer. The posterior nares were cleansed thoroughly every day by means of the post-nasal syringe, with a solution of chlorate of potash, chloride of sodium, and carbolic acid. This relieved the vomiting and sick-headache. Tonics and good nutriment were given, and as soon as she was restored to sufficient strength the galvano-cautery was applied to the diseased tissue in the vault. Two applications were required before it was entirely removed. After the disappearance of the tissue and the cessation of the discharge, the nausea and sick-headache left, her appetite returned, and it was surprising to note the rapidity with which she regained her flesh and strength.

CASE IV.—The most interesting and characteristic case of this affection came under my care last October. Miss Z. M.—, aged thirteen years, a bright, well-developed, and well-nourished girl; scrofula and phthisis markedly hereditary from both parents. One year ago last February she had scarlet fever, but it was followed by no observable sequelæ at the time.

* MEDICAL RECORD, New York, Dec. 30, 1876, p. 840.

Last February, one year after, she began to have trouble in her throat and posterior nares, accompanied by deafness. She had also a discharge of clear but thick viscid mucus from posterior nares, and an irritation in throat producing cough. Since the trouble came on she has had a growing impediment in her speech, giving her voice a muffled, flat sound, depending on deficient enunciation of the nasal consonants. She snored, and frequently started up suddenly while sleeping. She breathed chiefly through the mouth, because of stoppage in the nose, which, with her deficient hearing, gave her a very vacant, staring expression. Her friends had become quite anxious concerning her hearing, and had had her under the care of two aurists of distinction, during the past year, without benefit resulting. On examination, marked hypertrophy of the adenoid tissue was found nearly closing the post-nasal openings, extending into the fossæ of Rosenmüller, and encroaching on the pharyngeal opening of the Eustachian tubes, occluding them, and thereby causing deafness. The membranæ tympani were markedly concave, but otherwise normal. The opening of the Eustachian tubes by the catheter partially restored the hearing, but only for a short time. Removal of this tissue was advised as the only means of permanent benefit, and the use of the galvano-cautery recommended and readily assented to. The operation was performed with the use of an anæsthetic, Dec. 12th, my friend, Dr. E. V. Stoddard, assisting. The result was very gratifying. Her hearing was quite nearly restored, the hacking cough passed away, and the impediment in her speech also disappeared.

In many cases it is very difficult, often impossible, to obtain the assent of the patient, or parents in case of children, to any method of operative interference; consequently, in such instances, the removal of the tissue must be effected by a chemical means. Various caustic applications are used and recommended for such purposes; as, the Vienna paste, London paste, nitric acid, chromic acid, nitrate of silver, nitrate of zinc, etc. The one best adapted for these applications I have found to be chromic acid, on account of its rapid action and the peculiar advantage which it possesses over the others of causing but a very slight amount of pain proportionate to the destructiveness of tissue.

From a number of cases, I will cite the following as a typical one in which it was used. Frank F., an active, bright boy of thirteen years; home, San Francisco, Cal.; attending school in Oswego. He had been troubled with catarrh for several years, but otherwise enjoyed ordinarily good health. After an attack of measles three years before, his catarrhal trouble became much worse and his health impaired. He had a profuse mucous discharge from the posterior nares, proving a great annoyance to himself and friends, particularly at meals. There was great obstruction to nasal respiration, which on taking cold would be entirely cut off. The nasal resonance was gone from the voice, or, in common parlance, he spoke through his nose. During the night he snored loudly. Examination revealed a mass of hypertrophied adenoid tissue in the vault of the pharynx, about the size of a sparrow's egg, nearly filling the superior pharyngeal space, and from the openings in this tissue were poured out profusely a glairy mucous discharge. There was also moderate enlargement of the tonsils, but no other disease in or about the throat or nares to be found. I advised excision of the tonsils, and removal of the adenoid growth by the galvano-cautery, as the most expeditious means of accom-

plishing the desired end. The excision of the tonsils was allowed, but the removal of the adenoid growth by means of the galvano-cautery was objected to. Consequently I had to resort to the application of a caustic, and accordingly used chromic acid. About fifteen applications were required before the complete reduction could be accomplished, owing to the size and firmness of the growth. It was interesting, in this case, to note the cessation of the discharge with the disappearance of the tumor, and also the corresponding improvement in general health. Before this the boy had been subject to frequent colds, but has been entirely free from them since.

Thus it is a common experience to find more or less disease of this adenoid tissue in nearly every case of obstinate or aggravated post-nasal catarrh which one is called upon to treat, varying in degree from a mild catarrhal inflammation confined to the mucous membrane lining the crypts, and permeating all the channels, as we find in tonsillar catarrh, to extensive disease and hypertrophy of this tissue, blocking up the pharyngeal vault, and producing all the symptoms depicted in the most aggravated cases. And it is in these cases as useless to attempt, by ordinary mild astringent or saline washes, or sprays, to remove the disease thus located almost wholly below the surface, as it is to attempt to remove catarrh or hypertrophy of the tonsils by such means.

Excision or destruction of the diseased tissue is the only means of a radical, permanent, and positive cure.

EFFECTS OF "PITHING" ON THE VASCULAR SYSTEM.

A NEW PHASE OF THE SUBJECT.

By THOMAS W. POOLE, M.D.,

ONTARIO, CANADA,

AUTHOR OF "PHYSIOLOGICAL THERAPEUTICS."

By "pithing" is meant the destruction of the medulla oblongata and spinal cord. The operation is performed by cutting down posteriorly upon the cervical spine, just below the skull, separating two of the vertebrae, and thrusting a probe or stout wire first into the cranium and then down the spinal canal, where it is moved about freely, so as to break up and destroy the nervous substance.

It has been asserted on authority, and currently believed, that this operation causes general relaxation or dilatation of the arteries, and as the calibre of these tubes is under the control of the vaso-motor nerves, whose centres are thus destroyed, the experiment is quoted to prove that arterial dilatation is the effect of vaso-motor paralysis. As a consequence, it is also held that arterial contraction is depending on vaso-motor influence, and is best shown under vaso-motor excitation.

We have had the boldness to call in question the truth of the accepted vaso-motor theory, and in a recently published work, entitled "Physiological Therapeutics," we have attempted to show that this theory is quite at variance with the facts of disease and drug action. At present we propose to refer more especially to the effects of pithing, and before proceeding to the results of our personal observation, we shall refer, in brief terms, to Dr. Burdon-Sanderson's account of the operation, to which the reader may be disposed to turn for the full details, as contained in the "Handbook for the Physiological Laboratory." (Lindsay & Blakiston, Phila., 1873, pp.

244-246.) This eminent physiologist states that the arterial tonus is maintained "only so long as the artery is in communication with the vaso-motor centre," and that "if the medulla is divided immediately below the cerebellum, all the arteries are relaxed." To illustrate this, he enters into details of the "destruction of the nervous centres" by the manner known as pithing. A careful and studied perusal of what follows under this heading has satisfied us, and we think will also convince the candid reader of the work referred to, that the result of the operation, as there recorded, by no means sustains the assertion that the arteries are relaxed, and entirely fails to prove the point it is intended to demonstrate. Thus, Dr. Burdon-Sanderson finds the heart of the pithed frog empty, and that it bleeds considerably less when the ventricle is split open than the heart of an unpithed frog. The intestinal veins are distended. He finds the mass of the blood at rest "out of reach of the influence of the heart," presumably in the veins, which he tells us elsewhere are one-sixth more capacious than the arteries; but he makes no mention whatever of the condition of the arteries, the point on which the interest of the experiment entirely depends! This omission is very significant. If the arteries were relaxed and full of blood (as the experiment was specially designed to show), the left ventricle and aorta could hardly be empty; nor with the systemic vessels distended with blood could that fluid be properly said to be at rest "out of the reach of the heart."

With a view of ascertaining for ourselves what were really the effects of the destruction of the nervous centres on the vascular system, we have conducted a series of operations of the kind referred to on frogs, rats, kittens, and puppies, with the result that, so far from the arteries being relaxed or dilated with blood, we invariably found them empty, pale, and contracted, while, in marked contrast, we as uniformly found the entire venous system distended and its swollen tubes dark blue from the quantity of blood contained in them. We found this fact less palpably shown in frogs, owing to the early bifurcation of the aorta and its subsequent division into small branches. But in the mammalian subjects mentioned, the emptiness of the aorta and its chief branches, the smallness and paleness of the iliac artery contrasted with the corresponding dark and swollen vein, the prominence of the veins of the mesentery and viscera, so injected as to be easily traceable to their venous trunks, and the engorged portal vein, were too well marked to admit of doubt. The lungs were not congested, but were partially collapsed, as though the pulmonary artery, too, had contracted, shutting off the passage of blood; for the vena cavae were full, and the right ventricle bled on puncture rather more than its tiny cavity (in some of these subjects) might be expected to hold. We are satisfied from these observations that destruction of the nervous centres by pithing is not attended by dilatation of the arteries, but that, on the contrary, the arteries are so contracted as to have emptied themselves by forcing the blood into the veins, which were distended and prominent in consequence. We can now fully understand Dr. Burdon-Sanderson's statement as to the mass of the blood having come to rest "out of the reach of the influence of the heart."

These results show that this operation, so far from supporting the accepted vaso-motor theory, militates strongly against it; for the arteries are contracted, when, under the condition of nerve paralysis, they ought to be dilated. Nor can the distended condition of the veins be quoted in support of that theory, for it

is the arteries and not the veins which are under the control of vaso-motor nerve influence. The dilated condition of the veins is a purely passive or mechanical one, from having blood forced into them which was debarred from passing the round of the circulation as usual. For the reasons stated, we believe this obstruction was caused by the contraction of the pulmonary (in common with other) arteries.

Anatomists long ago pointed out, that in death from ordinary causes the arteries were invariably found empty. Hence the ancient notion that they were filled with air or "vital spirits." What we here state to be the effect of pithing is therefore an ordinary and by no means exceptional condition. This uniform contraction of the arteries in death proves that arterial contraction cannot be dependent upon vaso-motor nerve influence, since it occurs after nerve-force becomes extinct. It follows equally that arterial dilatation cannot be due to nervous paralysis, for under this very condition of the nerves the arteries are contracted and empty.

In this connection we are sure to be referred to the celebrated experiment on the cervical sympathetic, in which section of that nerve or ganglion has been shown to produce dilatation of the arterioles of the head and face, with other concomitants of that condition, including increased temperature; and it will be said that here, at any rate, nervous paralysis and vascular dilatation go together. We have fully considered this objection in the work referred to, and have shown that physiologists very frequently regard injury, section, or extirpation of portions of nervous tissue, not as producing paralysis, but as setting up temporary irritation in the remaining nervous substance, or in contiguous nervous tissues, and in this way producing for a time effects similar to those of nervous excitation. In addition to the authorities there quoted in support of this view, we are glad to be able to add that of Dr. Ferrier, who, in his "Functions of the Brain," records marked sexual excitement in a monkey, in whom the occipital lobes had been extirpated before it had recovered its appetite for food, and while still much physically prostrated. Dr. Ferrier remarks: "The excitation of the [sexual] appetite cannot have arisen *ab extra* in the usual manner, for the companion monkey was also a male, and resisted the proffered embrace. It would therefore seem to have been caused by central irritation, and the conditions were such as to excite by inflammatory irritation the centres of the sexual feeling, supposing these to be in immediate contiguity to the line of section of the occipital lobes" (p. 198). Dr. Burdon-Sanderson finds the vagus ganglion of the septum of the frog's heart excited to increased display of its motor power by "the mechanical irritation" occasioned by excision of the sinus venosus (inferior vena cava) from the right auricle, "preferably by a blunt scissor." (Handbook, etc., pp. 277, 278). In view of these authoritative examples, in addition to those elsewhere adduced, proving that physiologists are accustomed to regard traumatic injury of nervous tissue as a source of nervous excitation, we ask for the application of the same principle to section of the sympathetic. In that case, the dilatation of the cranial arteries will be regarded as the effect of excitation of the vaso-motor fibres of the sympathetic, produced by the operation. Many reasons might be shown to justify the opinion that the real function of the vaso-motor nerves is to dilate the arteries and not to contract them. Indeed, it is only on this view of the case that the relations of the vaso-motor nerves to the arteries admit of explanation at all. Take a familiar

example. A little brandy is an undoubted stimulant. It produces flushing of the face, and other signs of arterial dilatation. If the accepted vaso-motor theory were true, there ought, on the contrary, to be arterial contraction, paleness, etc., for on that theory excitation of the vaso-motor nerves by a stimulus causes the arteries to contract, and arterial dilatation is the result of nervous paralysis. To account for the phenomena of this simple case, then, it is necessary to assume that the glass of brandy has paralyzed the vaso-motor nerves, which is manifestly absurd. On the other hand, if we regard the stimulant as temporarily increasing the *dilating* power of the vaso-motor nerves, and these in turn expanding the calibre of the arteries, permitting an in-rush of blood (as also occurs in blushing), the facts and the theory are in accord, and the explanation natural and consistent. Similar examples might be multiplied indefinitely; and indeed, wherever the accepted vaso-motor theory is thus tested in the phenomena of disease and drug action, it will be found inconsistent with the facts.

It can also be shown that excitation of the cranial vaso-motor nerves, as a result of section of the cervical sympathetic, is not inconsistent with the supplementary part of that experiment in which Dr. Brown-Séquard has shown that faradization of the cranial end of the cut sympathetic reduces the dilated arteries to their normal calibre, and thus negatives the effects produced by the irritation of the section. For it is well known and generally admitted, that the electric current relieves pain and produces anaesthesia, at least for a time in nerve-trunks. Anaesthesia is only another name for paralysis, and anaesthetics are paralyzing agents (Dr. Anstie). What more natural, then, than that the electric current, by paralyzing the cranial sympathetic, and thus snuffing out, as it were, the excitation of those nerves induced by their section, should put an end to the *dilating* power of the vaso-motor nerves, and with this restore the normal calibre of the vessels? For further proof of the paralyzing effect of electricity on nerve tissue, see Matteucci's experiment on the spinal cord of the living rabbit, which, during the passage of the current, may be cut, pricked, burned, etc., without eliciting from the animal any sign of pain. We cannot dwell on this part of the subject here, but it is fully discussed in our "Physiological Therapeutics."

We have seen, conclusively, as a result of the destruction of the nervous centres by pithing, that contraction of the muscular coats of the arteries, with reduction of their calibre, takes place independently of nervous influence, of which the fact that the arteries are found contracted* and empty in death from general causes, is a further proof. If, then, as we contend, the influence of the vaso-motor nerves is to *dilate* the arteries (an influence arrested by paralysis or death), the question arises, To what source are we to look for the contractile power of the arteries? The teachings of physiologists themselves supply the answer: to the inherent contractile power of the muscular tissue of which these tubes are in part composed, and with which all physiologists declare this tissue to be richly endowed. We have quoted these authorities at length, on this part of the subject, in the work referred to. It is true they do not assert or admit the independence of muscular contractile power, apart from nerve influence, but they sometimes come so near asserting it that one can hardly help imagining that they refrained from asserting it more through

deference to established opinion than from a positive conviction that the assertion was unjustified. Thus Prof. Kuss, of Strasbourg, in his Lectures on Physiology (Duval, Amory), states that "muscular contractility is a purely physical property of elasticity: the rigidity of the corpse is a phenomenon of the same order as muscular contraction in the living body" (p. 88). Dr. Carpenter says of certain post-mortem muscular contractions, that they are "due to the inherent contractility of muscles, and not in any degree dependent upon the operation of the nervous system" (Physiology, before quoted, pp. 327, 328). This eminent physiologist combats the teachings of some physiologists, "that muscles, though not depending on nerves for their peculiar vital power [of contractility], are yet dependent upon them for the exercise of it" (p. 325). If the "hypothesis" here repudiated by Dr. Carpenter be untrue, then the opposite of that proposition must be true, namely, that muscles are neither dependent upon nerves for their contractile power, nor for the means of exercising it, which is all for which we contend. Drs. Todd and Bowman, in their Physiological Anatomy, "protest against the doctrine which assigns the spinal cord as the source of muscular irritability. . . . It is contrary to all analogy to assign to one tissue the power of conferring vital properties on another. . . . And surely it is too much to suppose that a tissue-like muscle, so complex in its chemical composition, and so exquisitely organized for the development of its proper force, should be dependent on the nervous system, or a portion of it, for its contractile power" (pp. 302, 303). It will be seen, from these quotations, how very little we claim beyond what is fully admitted, when we ask for the recognition of the independent, as well as inherent, contractile power of muscular tissue in the arterial walls.

The points we have endeavored to establish in this paper may be summarized as follows:

1. Destruction of the nervous centres is attended, not by relaxation of the arteries, as has been asserted, but by a marked and uniform contraction and emptiness of these tubes.
2. Arterial contraction cannot be dependent on nervous agency, nor can arterial dilatation be the effect of vaso-motor paralysis.
3. The vaso-motor theory at present in vogue is erroneous, untenable, and at variance with the facts it is intended to explain.
4. There are strong and valid reasons for believing that the real function of the vaso-motor nerves is (not to contract) but to dilate the arteries.
5. Similarly strong and valid reasons exist for the opinion that the varying calibre of the arteries is due to the antagonism between the dilating influence of the vascular nerves, and the inherent contractile power of the muscular fibres of these tubes; contraction or dilatation resulting in proportion as one or other of these opposing forces predominates.

The practical importance of these views will be apparent in their application to the phenomena of disease and the action of that large and constantly increasing class of drugs known to act on the circulation through the agency of the nervous system. We cannot even glance at these interesting results here, but have done so elsewhere, in the publication mentioned, to which we invite the reader's candid attention. We claim that the theory, here inadequately presented, serves to explain in a natural and consistent manner many phenomena of disease and drug action at present involved in obscurity or perplexing contradictions.

* Dr. W. B. Carpenter, Human Physiol., 5th Amer. Ed., p. 334, etc.

JABORANDI AND ITS ALKALOID IN CHOLERA.

By D. B. SIMMONS, M.D.,

YOKOHAMA,

SURGEON TO THE KERR GENERAL HOSPITAL, AND PHYSICIAN TO THE CHOLERA PAVILION HOSPITAL.

At the commencement of the present epidemic of cholera in Japan I determined to give, in its treatment, the still fashionable medicine jaborandi and its alkaloid a fair trial.

Though my observations are far from complete, or in all respects perfectly conclusive, I have seen enough to convince me that we have in this drug a remedy of undoubted value in the treatment of this disease.

Thus, I find that, in the usual complete or partial suppression of urine so common in such cases, the specific effect of the medicine shows itself with almost equal frequency in exciting activity of the kidneys as of the skin and salivary glands, its administration being followed in some cases by a copious secretion of urine, with great relief to all the symptoms. When the fortunate result is not obtained in so marked a manner, the tendency to the development of uremic symptoms is apparently less common.

When too great prostration does not exist, the copious perspiration which follows its use is attended, after the first few minutes, with a decided improvement in the character of the pulse; the sense of oppression is relieved, and a reaction often ensues which is far more natural than when produced by alcoholic or other stimulants, and with apparently less tendency to secondary fever.

A curious fact is often observed, that even when there is considerable vomiting, a drachm of the fluid ext. of jaborandi, at best a nauseous dose, is retained till its specific effect is produced. In one case in which there was almost constant vomiting, this symptom nearly ceased on my administering $\frac{1}{4}$ grain of pilocarpin hypodermically. I find, however, that this remedy has little effect in the more desperate cases, attended by perfect collapse. In fact, I am by no means sure that it does not tend to hasten the already rapidly approaching fatal termination.

PROTOCOINE IN THE DIARRHOEA OF CHOLERA.

This drug has disappointed my expectations somewhat as a remedy for the diarrhea in this disease. In two cases only where the characteristic rice-water discharges were terribly profuse, two three-grain doses of this drug, administered in quick succession, was followed by their almost immediate and complete arrest.

In those cases, however, in which the discharges are small, with more or less mucus, I have been able to obtain very indifferent results with protochine.

TREATMENT OF DIPHTHERIA IN THE GRAND DUCCAL FAMILY.—The cases were treated by Oertel, and his measures were those which he has used for twelve years. They consisted of isolation, inhalation of a disinfectant spray every hour and a half, for fifteen minutes, and inhalation of hot steam (112 to 122 F.); 2.5 per cent. solutions of potass. chlorate, and 0.1 per cent. solutions of acid salicylic were employed. Lime-water and chlorine-water were also used. Internally, large doses of quinine or salicylic acid were given; also alcohol, iron, and other drugs p. r. n.; yet the cases all got well.

Progress of Medical Science.

PERMANGANATE OF POTASSA IN THE TREATMENT OF CHRONIC OTORRHOEA.—Dr. Howe claims to have had excellent results in chronic otitis media purulenta from the use of permanganate of potassa. The solution varied in strength with the severity of the case, two grains to the ounce being used in the milder cases, increased to four, six, or even eight grains to the ounce in the more severe. After thorough syringing with tepid water, a few drops of the permanganate solution were poured into the ear, and allowed to remain five or ten minutes, if it produced no smarting or burning sensation. If decided inconvenience followed, however, it was washed out sooner. When the discharge was at all abundant this was repeated twice daily, and if very profuse, the ear was kept clean by more frequent washings with water alone. Of the 53 cases treated in this manner, 40 have entirely recovered in an average time of thirty-eight days; in 6 the discharge recurs at intervals; in 4 it is continual, but lessened as to quantity and the fetid character of the odor; in 3 it still persists. These results are rather better than follow the use of most of the remedies recommended in this disease. Dr. Howe thinks that in this disease permanganate of potassa can be relied upon to heal safely, quickly, and easily.—*The Buffalo Medical and Surgical Journal*, August, 1879.

ECZEMA OF THE PALM.—The opinion advanced by Dr. Spender, of Bath, that all so-called cases of psoriasis palmaris are either modified forms of eczema rimosum or dermatosyphilis, has given rise to some discussion in the British journals. Dr. Living fully agrees with this opinion, thinking that simple psoriasis so rarely attacks the palm or sole, that practically we may say those parts are exempt from it. Dr. McCall Anderson, while acknowledging that eczema of the palms often assumes an appearance resembling psoriasis, is unwilling to admit that these cases are all forms of eczema. Eruptions limited to these parts may be, in his opinion, eczema (especially eczema rimosum), syphilis, or psoriasis; the first being more frequent than the second, and the last the rarest of the three. Dr. Anderson thinks that the recovery of certain cases under treatment adapted to psoriasis and unsuitable to eczema, is strong proof of the existence of the former disease. Both he and Dr. Living call attention to the possible influence of the gouty and rheumatic diatheses over these palmar affections. The acute or subacute form, Dr. Living thinks, is best treated by the application of water-dressing, lead lotions, or linimentum calcis, according to circumstances; the gist of the treatment being never to allow the dressing to get dry. Pretty free purging is generally indicated. The ordinary chronic forms are well treated by the application of lead-ointment; but in all cases the hand should be rested, covered, washed little, and the ointment constantly applied. In those obstinate cases in which the skin is extremely hard, brittle, thick, and cracked, ointments produce no effect, and other means must be adopted to get rid of the outer cuticle, which entirely prevents any chance of cure. This is best done by the constant application, night and day, of a lotion of liquor potassæ (from two to four drachms of liq. potass. to eight ounces of water is usually strong enough). The hand must be enveloped in rags kept constantly wet with the lotion, and covered with thin gutta-percha, or something of the kind. This treatment must be continued until the

cuticle is thoroughly white and macerated, when it will peel and rub off readily. The process may require to be repeated until the epidermis is reduced to its natural thickness and is thoroughly soft; the skin may then be treated with ointments and glycerine in the usual way. Chronic eczema rimosum of the hand is one of the few forms of eczema in adults that is often benefited by the internal use of arsenic.—*The British Medical Journal*, July 5, 1879.

FOREIGN BODIES IN THE BRAIN.—Dr. Wharton has collected three hundred and sixteen cases in which foreign bodies were lodged in the brain, a large proportion of them being gleaned from the "Surgical History of the Rebellion." Of this number, one hundred and sixty recovered, while one hundred and fifty-six died. In one hundred and six the foreign body was removed, death following in thirty-four, recovery in seventy-two cases. No attempt was made to remove the foreign body in two hundred and ten cases, death resulting in one hundred and twenty-two, recovery in eighty-eight. Ten patients are classed as having recovered, who became sufficiently well to attend to their regular occupations, but subsequently died, at periods varying from three years to fifteen years, from the effects of their injuries. Further examination shows that of the one hundred and sixty recoveries forty-nine were not complete, the patients afterward suffering from epilepsy, vertigo, impairment of mind, incapacity for physical exertion, paralysis, loss of sight and hearing; in one hundred and eleven none of these symptoms were noted. Of these one hundred and eleven perfect recoveries, the foreign body had been removed in fifty-six, and allowed to remain in forty-five. From these figures it is seen that after removal of the foreign body recovery followed in 68 per cent. of the cases, whereas when this operation was not performed 61 per cent. of the cases died. Moreover, of the recoveries following removal, 78 per cent. were perfect, while but 51 per cent. of the recoveries with the foreign bodies *in situ* were free from grave symptoms.—*Philadelphia Medical Times*, July 19, 1879.

TYROSINE EXCRETED BY THE STOMACH IN A CASE OF CANCER OF THE UTERUS.—In a case of cancer of the uterus, the small amount of urea (6 to 7 grammes) excreted by the kidneys induced M. Bruneau to search for it in the saliva and in the vomited matter. The results were negative, but microscopical examination of the vomit showed crystals of tyrosine in the form of long, brilliant needles gathered together in masses. On evaporating some of the liquid with nitric acid, yellowish crystals of the nitrate of nitrotyrosine were formed, which took a brownish red color on the addition of ammonia. As the presence of tyrosine is always accompanied by a diminished production of urea, it accounts for the small quantity of the urea in this case.—*Journal de Médecine*, May, 1879.

ESERINE AND Pilocarpine in Episcleritis.—Prof. Seeley reports two cases of episcleritis that were treated by instillations of eserine. Recovery in both cases was very rapid, ensuing in one case in two weeks, and in the other in ten days. Dr. Wecker, of Paris, says that the treatment that has given him the best results in episcleritis consists in the hypodermic use of pilocarpine (five drops of a solution of twenty centigrammes to two grammes). He makes the injection in the morning while the patient is still in bed. He says this treatment sensibly abbreviates the slow course of the disease, some patients being entirely cured by eight or ten injections. Along with

the injections, he always prescribes the iodide of potassium, and for debilitated subjects preparations of iron.—*Cincinnati Lancet and Clinic*, July 19th.

THE STIGMATA OF MAIZE AND THE ARENARIA RUBRA IN DISEASES OF THE BLADDER.—As the stigmata of maize are a very recent and as yet but little known addition to the materia medica, the following *résumé* of the conclusions reached by Dr. Dufau, both from personal observation and from the reports of others, will undoubtedly prove interesting:

1. The stigmata of maize have a very marked, though not always a favorable action in all affections of the bladder, whether acute or chronic.

2. In acute traumatic cystitis, and also in gonorrhœal cystitis, they have a very marked diuretic action, but at the same time increase the pain; hence they should not be employed in these cases.

3. The best results have been obtained in cases of uric or phosphatic gravel, of chronic cystitis, whether simple or consecutive to gravel, and of mucous or muco-purulent catarrh. All the symptoms of the disease, the vesical pains, the dysuria, the excretion of sand, the ammoniacal odor, etc., etc., rapidly disappear under the influence of the medicine.

4. The retention of urine dependent on these various affections often disappears as improvement progresses, but the use of the sound must sometimes be continued, in order to empty the bladder completely.

5. The stigmata of maize have very often produced a cure after all the usual internal remedies had been tried in vain, or with only partial success. In other cases the ordinary methods of treatment, which had at first proved more or less entirely useless, became efficacious after the stigmata had been administered for a time, and had, as it were, broken the ground for them. Most frequently the stigmata alone sufficed for the cure, but still in some cases the effect was incomplete, and it was found that the treatment could be varied with benefit. Injections and irrigations of the bladder also proved useful adjuncts to the maize.

6. As the stigmata of maize are a very powerful, though at the same time entirely inoffensive diuretic, they have also been employed with the best results in cases of heart disease, albuminuria, and other affections requiring diuretics. Cases have been reported in which the urinary secretion was tripled and even quintupled in the first twenty-four hours, and others where the exhibition of the drug was continued for two or three months without the slightest untoward effect.

7. The best preparations of the stigmata are the extract and a syrup made from it. The decoction is unreliable and uncertain. The syrup, the usual dose of which is two or three teaspoonfuls per diem, must be largely diluted, and for this purpose either hot or cold water, or a decoction of the stigmata may be used. The taste of this mixture is very agreeable. It should be given fasting.

Another remedy for diseases of the bladder that has lately begun to attract attention, is the *arenaria rubra*, a plant of the order of caryophylleæ. It is known in Algeria by the common name of *sablina*, and has long enjoyed repute in Malta and Sicily as a household remedy for the treatment of gravel and catarrh of the bladder. It seems to be useful in the same line of cases as the stigmata of maize, but as yet our knowledge concerning its powers and uses is very limited.—*Le Courier Médical*, May 3d and July 12th.

DR. J. MARION SIMS.—Among the passengers on the Germanic, which arrived in this city Sept. 6th, we notice the name of Dr. J. Marion Sims.

THE MEDICAL RECORD :

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 13, 1879.

PREVENTIVE MEDICINE.

THE day in which the idea that the whole function of medical men began and ended with the treatment and cure of disease has passed away. There has been what is sometimes called "a new departure" in medical science, and the profession has revived the old doctrine that, in addition to administering drugs, something may be done toward the prevention of disease. The rigorous separation of the sick from the healthy had its origin under the Mosaic dispensation. State medicine is fully set forth in the old Hebrew ordinances, and had the sanction not only of the most cultivated race in the world, but of Divine authority.

There is an apathy and stagnation regarding the importance of State medicine and public hygiene which has its foothold, to a very great extent, in the too negative character of past observations and published statistical results. Those who object to sanitary measures have been accustomed to allude to the negative results of sanitary expenditure, and have boldly asserted that mortality statistics afford no evidence of sanitary progress. In a former article we had occasion to speak of the speciousness of such argument, and what we then said regarding another subject, intimately related to actual population, is equally true with reference to sanitation and mortality—namely, that even a stationary death-rate must be accepted as evidence of progress.

It seems to us self-evident that, if by the aid of sanitary science the rate of mortality can be made stationary, notwithstanding the aggregation to large towns and cities, it must be regarded as one of the triumphs of improving sanitary organization.

At the recent meeting of the British Medical Association, Dr. Andrew Fergus, President of the Faculty of Physicians and Surgeons of Glasgow, read an able address on preventive or State medicine, in which he

gave an analysis of the whole of the Registrar-General's returns, and from these he shows clearly that the death-rate in England and Wales is declining; or, in other words, that the mean duration of human life is increasing. The marked decline in the fatality of fever, especially of typhus, he justly attributes to the benefits arising from the adoption of thorough sanitary measures.

There are one or two points in his address to which we wish to call especial attention.

"The first facts that strike us," says Dr. Fergus, in speaking of the lessons drawn from the Registrar-General's returns, "are the increase in the diarrhoeal group, the addition of a new zymotic, viz., diphtheria, which does not appear until 1851, and the small diminution of typhoid in the fever group. If we bear in mind that these are excremental pollution diseases, I believe we shall find the reasons of this increase in the fact that we have been careless in the disposal of our excreta, and have been drinking water and breathing air contaminated by it in a state of decomposition."

In the reports which Mr. Simon and Dr. Greenhow have made to the Privy Council can be found the following significant paragraph: "The excess in mortality has in all cases been coincident with one or other of two definite local circumstances: (a) the tainting of the atmosphere with the products of organic decomposition, especially of human excrement; or (b) the habitual drinking of impure water."

It is an opinion which has generally prevailed that removal of refuse-matter by water is one of the most effectual methods that can be employed, and just here Dr. Fergus's experience becomes especially interesting. We can do no better than to use his own language: "When I first turned my attention to public health, I had the most perfect faith in water-carriage for removal of the refuse of communities; but investigation, experiment, and experience have obliged me to change my opinion. It is a popular opinion that water is a purifier, but in regard to human excretal matter it is a mere shunter. It merely removes the nuisance from my door to deposit it somewhere else, but does not destroy it."

In accordance with this view, he reasons that these offensive matters should not be passed into rivers or into the sea. The results of his experiments have been, that when kidney and bowel secretions are kept separate, decomposition goes on very slowly; if they are mixed, it is more rapid; and if water be added, it is much accelerated. Therefore, as chemical science has told us that water of itself and by itself has no purifying power, we must go back to earth, the original mother of all organized matter, for reliable aid in preventing putrefactive decomposition.

After years of study and observation, this able observer reaches the conclusions that, "if it is true

that organic poisons producing disease may pass from sewage; if it is true that cholera, diphtheria, typhoid fever, and diarrhœa are traceable to taking into our systems, by air or water, the results of decomposition of human excreta; if it is true that these diseases and others from the same causes swell our death-rate and carry off some of the most valuable of our population, then I affirm that the only true sanitary solution of our difficulties is, that all excreta shall either be returned to the earth, or subjected to chemical action rendering decomposition impossible; and I am, furthermore, sure that if a little of the time, skill, and ingenuity, and a one-thousandth part of the money that have been devoted to water-carriage had been spent in investigations in this direction, the problem of the sewage question would have been solved long ago."

The system of water-carriage, as Dr. Fergus says, was hailed as a boon both of comfort and of decency, and the popular opinion, at least, has been that there was no better way of avoiding the evil consequences following the prolonged presence of these matters than by removing them by means of an abundant water-supply. It does not necessarily follow, however, if this be not true, that we should return to the abominations of the old privy system, for the resources of sanitary science are numerous and effective.

Commenting upon this address, the editor of *The Medical Press and Circular* says that appeal can be made to positive facts, which prove the possible and salutary results of preventive medicine, and he refers to instances in which the death-rate has been reduced, within a single quarter, from 23 per 1,000 to 8 per 1,000 by a new system of sewerage and new water-works.

There can be no reasonable doubt that the best way to treat every disease is to prevent its occurrence. It is not always possible to do this, but certainly it cannot be safely assumed that, because the disease does not come after precautionary measures have been taken, sanitation is of no avail. Maintain all communities and all houses in good sanitary condition: remove all magazines of decomposing organic matter which are ready for explosion from the presence of a single spark. The terror which an epidemic disease inspires renders it almost impracticable to institute requisite preventive measures, and that which has not been effectively accomplished before the outbreak of the epidemic, must, to a large extent, be postponed until its ravages have passed.

The ideas which Dr. Fergus has presented in his address are worthy of consideration by our ablest sanitarians.

AN APPEAL FOR AID FOR MEMPHIS.

On the fourth of September the Howard Association of the city of Memphis made a public appeal for moneyed assistance in resisting the deadly march of the

epidemic of yellow fever. For two months they have battled with the dread destroyer, and now find their treasury exhausted, several hundred sick and convalescents to be provided for, and a large number of nurses to be paid. In their appeal they state that they were hopeful in the beginning that, with the fund then on hand, they would be able to provide and care for the sick; but now, at the end of two months, during which the disease has been in their midst, and with two long months of danger before them, they find their resources exhausted and are compelled to ask for substantial aid. In the year 1878 a like appeal was heard, and the ready heart and willing hand of the medical profession went searching into its pockets, and there came forth that which did honor to the charity of the medical men of the nation.

To the charity of a common people the Howards now appeal for aid in alleviating the suffering of a common brotherhood.

The appeal in 1878, made in the name of the medical profession, and also by the Howard Association, met with a prompt and substantial response, and in 1879 like appeals cannot go unheeded. While our inclination may be to send aid more especially to our own representatives in the field, to their widows and to their orphans, we cannot turn a deaf ear to the statement, "if help is not speedily furnished, we will be compelled to abandon the work we have been engaged in, and leave hundreds to suffer and die for want of a Howard's helping hand."

HEALTH AND RECREATION.

The summer vacation is practically closed. The shortening days and the approach of foul weather has already reopened the offices of many of our physicians. They have been out for recreation and have returned ready for work. They have sought recreation believing it to be an essential to the proper preservation of health and the prolongation of life. They endorse the work and play side of the question, and regard the one as essential as the other if the best practical results are to be obtained. Not long since Dr. B. W. Richardson, F.R.S., delivered a lecture at the London Institution, in which he took the position that, both in the young and the old, there was no difference between work and recreation other than one of sentiment. He believes that the reason why such excellence, physical and intellectual, was attained in the short and brilliant bloom of Greek history, was because in the Greek's career, from beginning to end, there was no such thing as work or play, but only life.

Commenting on this lecture, the *London Times* says that, if we could by some means approach the ideal handed down to us by history, we should in a generation or two attain a degree of health which no mere sanitary provisions, in the usual sense of the term, can ever supply, and the same sentiment is as practically applicable here as there. There are conditions of life,

such as pertain to our climate and manner of living, which perhaps will prevent us from realizing the joyousness of Grecian life. But, besides these, there is the unequal struggle for existence, which dooms so many to the monotonous round of toil until the whole body lends itself to the drudgery like an automaton.

"There is a striking exception," says the learned lecturer, "in the happy class who find in mental labor, of a varied and congenial sort, that diversity of work which is truly a recreation of the healthy and vital powers." To confirm this view, he refers to the conclusion, reached by Dr. Beard, of this country, after examining the life-value of five hundred men of the greatest mental activity, and an equal number belonging to the rest of society—which is, that the brain-workers have a life-value greater by fourteen or twenty years than those whose pursuits are chiefly physical. Dr. Richardson, as well as others, have ascertained that the most influential in prolonging human life is the recreative character of intellectual labor.

Again, the *Times* alludes to Dr. Beard, who describes brain-work as the highest of all antidotes to worry. Scientists, physicians, lawyers, clergymen, orators, statesmen, literati, and merchants, when successful, are happy in their work without reference to reward, and work on in their callings long after the necessity has ceased. Good fortune gives good health, and nearly all the money in the world is in the hands of brain-workers, whose life is one long vacation.

Whether it be true or not that the difference between work and recreation is merely sentimental, there is comfort in mental and physical recreation which can be obtained only by absenting one's self from the drudgery of routine and, to a great extent, automatic labor. A grain of consolation for so doing can be obtained from Plato, who warned his readers against over-cultivation of mind, which, so far from being recreative to the health of the body, would be positively injurious, just as an over-cultivation of muscular power might prove mischievous.

Profiting by the suggestion, we may therefore, avail ourselves of every opportunity that presents itself to resort to the sea-shore or to the mountains, in the belief that by so doing all life will be made healthier, happier, and longer.

ANTIMONY IN PHTHISIS.—In phthisical patients attacked with bronchitis there is a condition of the bronchial mucous membrane fraught with peril to the patient. The membrane is congested, swollen, dry, and coated with a thin but tenacious and irritating secretion. This condition may continue for days, producing fever, and paroxysms of ineffectual coughing which exhaust the strength of the patient. In these cases nature fails to bring relief, and our knowledge of the physiological properties of drugs becomes available. There are several that will excite the secretion, but the best is antimony. This, given in doses of $\frac{1}{2}$ th of a grain every hour, will, after a dozen doses, relieve the patient and avert his danger.—*Andrew Clark in Address at Brit. Med. Ass'n.*

Reviews and Notices of Books.

LONG LIFE AND HOW TO REACH IT. By JOS. G. RICHARDSON. American Health Primers. Philadelphia: Lindsay & Blakiston. 1879.

WE have already referred very favorably to the American Health Primers, and this one, which is the second on the list, is likely to maintain the reputation of the series. The author offers us no *elixir vite*, but gives plenty of sensible advice, and those who have the self-control and intelligence to adopt it will reach all the length of days that their constitution allows them.

A TABULAR HANDBOOK OF AUSCULTATION AND PERCUSSION, for Students and Physicians. By HERBERT C. CLAPP. With four plates. Boston: Houghton, Osgood & Co. 1879. 8vo. pp. 97.

WITH the many handbooks on physical diagnosis now in the field, any new one must have some special and notable merit in order to justify its existence. We confess that we are unable to see any great necessity for the publication of the present book. It is simply a tabular presentation of the physical signs belonging to the diseases of the heart and lung, with a tabular analysis and description of the signs themselves. These tables are very well gotten up, and appear to be thorough and reliable. Still, they embrace nothing that is not found in other elementary textbooks. We might perhaps find fault with the author for not including diseases of the abdomen in his book, the physical signs of which being often so intimately related to those of the chest. It is certainly not the thing for a professor in physical diagnosis to teach that the inspiratory sound is caused in part "by the forcible separation of the walls of the pulmonary vesicles." That is not a fact, and is scarcely a plausible theory.

The four illustrations represent the position and relations of thoracic and abdominal viscera, and the name of the firm is a sufficient guarantee that the book is a finely printed one.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF TENNESSEE. 1879. Nashville: Printed at "The American" Book and Job Rooms, 48 Church Street.

IT is a volume of 215 pages with paper cover, and contains some interesting articles. The Roll of Honor contains the names of fourteen members of the society who lost their lives in the yellow fever service during the year 1878, and, in the report on the Roll of Honor made by Dr. Wise, a tribute of respect is paid to "the forty-two physicians who, in the city of Memphis, fell at the post of duty and upon the field of honor."

A valuable clinical report on yellow fever, with meteorological observations, is found in the paper by Dr. G. B. Thornton, of Memphis, on observations made in 460 cases. This is followed by an interesting paper regarding the introduction and dissemination of yellow fever by persons or personal contact, by Dr. W. T. Hope, of Chattanooga, Tenn. These are valuable contributions for study at the present hour.

TRANSACTIONS OF THE MICHIGAN STATE MEDICAL SOCIETY. For the year 1878. Lansing: W. S. George & Co., Printers and Binders.

THIS volume has a paper cover, and contains 330 pages. The minutes of the recording secretary make

up a large part of the book. These are followed by the annual address of the president, and nine papers on interesting surgical, medical, and obstetric subjects. The Report of the Committee on Necrology embraces memoirs of Drs. Abram Sager, Albert E. Leete, and Edward E. Hume. A pleasing appendix contains a report of the proceedings at the annual reception.

PROCEEDINGS OF THE CONNECTICUT MEDICAL SOCIETY. 1879. Published by the Society. Hartford, Conn.: Press of The Case, Lockwood & Brainard Co.

This volume, paper cover, contains 214 pages, and has, besides the report of the usual proceedings at the annual meeting, the President's Address; a dissertation on the Principles of Hygiene and Conservatism in their Mutual Relations to Surgery; the Report of the Committee on Matters of Professional Interest, which embraces several interesting subjects and makes up a considerable portion of the book; essays on Yellow Fever; Alcohol as a Therapeutic Agent; and The Insane Colony at Gheel; several obituaries; a List of the Officers and Members of the County Medical Societies; the Charter of the Medical Department of Yale College; the Charter and By-Laws of the Society; and the Code of Ethics of the American Medical Association.

The last is not the least important of the documents herein presented, yet it doubtless will receive the least amount of candid attention. It makes interesting reading, and should be sufficient to give the volume a local habitation in every medical library.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK. For the year 1879. Syracuse, N. Y.: Truair, Smith & Bruce, Printers.

This volume, containing 700 pages, presents an external appearance that is creditable both to the committee on publication and to the printers. In addition to the regular order of material which enters into the contents of the book, we notice the minutes of the Seventieth Annual Meeting held February 1, 1876. This completes the published record of meetings.

The readers of THE RECORD have already had opportunity to read and to study many of the papers which were read at the last annual meeting of the society; but as we glance at them in their new home we find that they have lost none of their original excellence and interest. According to resolution, the metric system finds its place in the body of the work, and although a few errors have found a lodging-place here, they must be regarded as no more than the tares so commonly seen in a good field of wheat. They have been recognized by the secretary, who has directed attention to them in the corrigenda at the end of the list of county medical societies. The volume contains the list of officers and members of every society entitled to send delegates to the State Medical Society, and, with one or two exceptions, these have been corrected up to the time of the last annual meeting of the various county medical societies. This is a commendable feature of the book, and reflects credit upon the industry of the secretary.

Space does not permit of an extended review of each paper, and we must be content with the statement that in general they are good; some of them very excellent, and are from gentlemen of deserved and recognized position in the medical profession.

This volume will make a valuable addition to the series which contains the transactions of the Medical Society of the State of New York.

Reports of Societies.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

Third Annual Meeting, held in the City of New York, August 26th, 27th, and 28th, 1879.

(Concluded from page 232.)

WEDNESDAY, AUGUST 27TH.—SECOND DAY.—MORNING SESSION.

THE first paper on the second day was one by DR. H. G. PIFFARD ON

VIOLA TRICOLOR.

The first part of it was devoted to a *résumé* of the literature of the subject, in the course of which he quoted at large from Cazin, who has experimented considerably with the drug, and used it with success in practice. He then read as follows from a brief article upon it, written by himself in the American edition of Phillips's *Materia Medica and Therapeutics*, which has just been published by Wm. Wood & Company, and of which he is the editor:

"*Active Ingredients.*—Little known. Boullay failed to find violine in the plant. (Gubler.)

"*Physiological Action.*—A strong infusion made from $\frac{3}{4}$ ss. to $\frac{3}{4}$ j. of the herb, without the root, does not give rise to any suspicion that it contains violine or emetiu. Its action is exceedingly mild; sometimes proving slightly laxative, at other times diuretic; as a rule giving rise to very little disturbance.

"*THERAPEUTIC ACTION.*—*Viola tricolor* has long been a favorite in France in the treatment of eczema capitis et faciei, and the editor has employed it for many years with great satisfaction in chronic cases of this affection. The watery preparations have appeared to answer better than the alcoholic, and our usual procedure is to give it in infusion, combined with purgative doses of senna for the first few days. Afterwards the violet is continued alone. For children Cazin macerates $\frac{3}{4}$ j. to $\frac{3}{4}$ ij. in half a pint of cold water for twelve hours, then boils the infusion and adds a little milk and sugar. This amount to be taken daily. . . . The imported herb should be employed, and care taken to procure a good quality. Most of it in the market is inferior."

Dr. Piffard exhibited various specimens of the drug, procured both in this country and abroad, and stated that it was very difficult to get two that were at all alike. He also showed a fluid extract which was made from some that he had had imported. He believed it to be of the greatest service in eczema about the upper part of the body, and especially the head; while when the affection was situated on the lower part of the body he had found it to be frequently aggravated by the drug. The dose of the fluid extract for adults was a fluid drachm, and for children five to ten minims.

The paper was discussed at length by Drs. Taylor, White, Hardaway, Fox, Sherwell, Wigglesworth and Heitzman.

The next paper was by DR. VAN HARLINGEN, and was devoted to

A CASE OF HITHERTO UNDESCRIBED VESICULO PUSTULAR DISEASE OF THE SKIN

The patient was an unmarried German woman, thirty-nine years of age, whose family history was good, and who had never had any tendency to scrof-

ula. The skin trouble began at a very early age, but was noticed in an aggravated form when she was fifteen years old. It had continued ever since, but was always somewhat better in the early autumn than at any other time of the year. On examination it was found that there were two forms of disease present. The first was an eczema, ill-defined and irregular, and principally located on the head, anus, and back; while the second, which was situated almost entirely on the legs and ankles, consisted of single lesions. These were large tubercles, distinct and solitary, oval in shape, and often of the size of a thumb-nail. They were slightly elevated, and in some a small amount of pus was found in the centre, which was depressed. When these tubercles began to form, there was first local itching, and then an urticarial elevation. In about eighteen hours they were fully developed, and had reached a size of from one to one and a half centimetres; looking somewhat like large mint-drops. Later, exudation took place, and finally depression in the centre; the fluid becoming pustular. The nodule might last altogether for years; but at length it became pigmented and sank to the level of the surrounding surface, a white spot always being left in the centre. Itching was not excessive, and there were no marked subjective symptoms. Iodide of potassium and bichloride of mercury were tried without benefit, and the only thing that seemed to cause any improvement whatever was the application of Dr. Bulkley's *liquor picis alkalinis*, which was employed for about a month before the patient passed from observation.

The lesion was at first supposed to be probably a scrofuloderm; but a microscopical investigation showed it to be of a purely inflammatory nature. There was nothing like a genuine cell-infiltration, such as is characteristic of the scrofuloderm.

After remarks upon the case by various members, Dr. S. SHERWELL read a paper entitled,

"TATTOOING OF NEVI."

At its commencement he passed around the instrument with which he had performed his operations, and which consisted simply of a bundle of coarse needles securely fastened together. It had been constructed by Dr. Sherwell himself. The paper, he stated, was supplementary to one which he had previously read before the New York Dermatological Society, and in which the method had been fully described. He wished now merely to speak of its continued success, and to describe one case in particular where the result had been very satisfactory. The patient was a lady of twenty-seven, who before he took her case in hand had been so disfigured that it had proved not only a source of annoyance, but also of positive detriment to her in obtaining the kind of employment that she was best suited for. The nevus was of the port-wine-stain order, and covered the whole of the chin. There was also a large patch of similar discoloration in the centre of the cheek. The latter was cured after one operation; but four had been performed upon the principal nevus. Two were extended over the whole surface, and two had been confined to those portions where there was the most disfigurement left after the two general tattooings. In one final operation, shortly to be performed, it was thought that the cure would be completed.

Dr. Sherwell stated that he had not changed his after-treatment since he had written his last paper, and that he was more than ever favorably impressed with the advantages of the application of collodion.

As mentioned before, he had hitherto used only an instrument of home manufacture; but at present Tiemann was making one for him which he hoped would prove even more serviceable. He wished it distinctly understood that the only naevi which he claimed to cure in this way were of the cutaneous variety.

In the discussion which followed the paper Dr. HARDAWAY spoke in the highest terms of the method of treatment by means of electrolysis, where a number of very fine needles were employed.

The next business in order was the report of the Committee on Statistics, which was made by the chairman, Dr. White, and which contained a special report on the subject of leprosy in this country. This was followed by the report of the Committee on Classification and Nomenclature, made through its chairman, Dr. Duhring, which recommended that carcinoma should be made a separate subdivision under Class VI. (New Growths), in the classification adopted by the Association last year. On motion, the recommendation was adopted.

AFTERNOON SESSION.

Dr. HARDAWAY, of St. Louis, read a report of
A CASE OF MULTIPLE TUMORS OF THE SKIN ACCOMPANIED BY INTENSE PRURITUS.

The disease in question had existed for twenty-two years, the patient now being fifty-one years of age. It was stated that the first lesions were "blisters," accompanied with itching, and that whenever the fluid from one of these blisters came in contact with sound skin, another similar lesion was produced. Not long afterwards the tubercles and tumors from which the patient now suffers made their appearance, and they have remained almost without change ever since. These tubercles and tumors (the latter ranging in size from that of a pea to that of a hickory nut), the writer said, were about in equal proportions, and a very curious feature of the case was that they were exclusively confined to the arms, hands, legs and feet; the area affected terminating abruptly at the shoulders and the knees. In their natural condition these lesions are covered with thickened epidermis, but, as a general rule, this had been removed by scratching. In some cases the tumors had come together, forming a large nodular mass, and, in addition, there were a number of flat plaques of the size of a child's palm. The intolerable and persistent itching was the most annoying feature of the case, and had given rise to much irritation of all the affected parts.

The patient had taken iodide of potassium, arsenic, mercury, and other remedies, and canterization of the tumors had also been resorted to. She thought the pruritus had diminished somewhat during the last few months; but the scratch-marks were still painfully evident. The peculiar limitation of area, the intense itching, the persistence of the lesions; and, notwithstanding all, the good general health of the patient, seemed to make this a unique case. Specimens from the lesions had been submitted to Dr. Heitzman for microscopic examination, who reported that there was marked hyperplasia of both the epithelial and connective tissue, and that he regarded the trouble as an inflammatory affection of the upper layers of the skin.

The next paper was by Dr. DUHRING, and entitled:
SUPPLEMENT TO A CASE OF INFLAMMATORY FUNGOID NEOPLASM.

The case referred to was the one in regard to which Dr. Duhring had written such an elaborate report for

last year's meeting, when he also brought the patient to Saratoga for examination. Before commencing the paper on this occasion, he exhibited a fine chromo-lithograph of a precisely similar case reported by Gehr, to which he had alluded last year. This, together with the cases of Piffard and Hebra (also referred to at that time), and the case under consideration, constituted all that had as yet ever been recorded. After the date of the last published notes in regard to it, October 1, 1878, the patient continued to exhibit signs of increasing cachexia, although a striking characteristic of her case was the variability of her condition from day to day. She suffered much from the profuse suppuration of the lesions, which was accompanied by the most extreme fetor. The consolidated tumors on the forehead increased to an enormous size, and at last presented a striking resemblance to a huge roasted tomato. As it gave her so much annoyance, and she was exceedingly anxious for the operation, it was finally removed by the galvano-cautery, and although the growth was remarkably vascular, there was no hemorrhage whatever. This was true, also, of the removal, in a similar manner, of a large tumor in the popliteal region. In this respect a striking contrast was presented by the two former operations, which were described last year, and which, as they were performed with the knife, were accompanied by a large amount of hemorrhage.

The case resulted fatally early in the month of May, 1879, and at the autopsy it was found that none of the internal organs were affected with the disease except the bladder, on the walls of which there was a growth corresponding in character to those on the exterior portions of the body. After a careful study of the whole case, Dr. Duhring concluded that the affection was, in all probability, of an inflammatory nature, although some of the microscopical features of the specimens from it seemed to point towards sarcoma.

DR. HEITZMAN regarded the disease, although presenting some very unusual clinical features, as distinctly sarcomatous, and thought the subsequent history of the case only substantiated the correctness of the views which he had expressed in regard to it last year.

DR. ATKINSON remarked that here the histological character of the tumors was, to a great extent, inflammatory; but combined with this were also the characteristics of a new growth. It was a case, therefore, which showed us the border-land between the two processes, and one that should teach us that we ought not to make boundary-lines for nature and expect her to keep strictly within them.

After remarks by DR. TAYLOR, who took Dr. Heitzman's view of the case, and DR. BULKLEY, who took Dr. Duhring's, DR. FOX said that he thought this discussion was an apt illustration of the conflict between microscopic and clinical investigation. Some erred on one side and some on the other; but he was satisfied himself that in all such cases as this, as long as our microscopical knowledge remained in its present state, the clinical features presented the surest basis for diagnosis.

As to Dr. Heitzman's unfavorable prognosis, DR. SHERWELL thought that it was pretty evident to all who saw the patient last year at Saratoga that she would die. The name fungoid neoplasm he thought a sufficiently good one in the present state of our knowledge of such cases, and especially as it did not exclude the idea of a sarcomatous element.

The last paper of the afternoon was by DR. HYDE, on

A VARIETY OF MOLLUSCUM VERRUCOSUM PRESENTING CERTAIN UNUSUAL FEATURES.

The patient was a native of Germany, thirty-five years of age, who, as far as known, had never had syphilis. Between two and three years ago he first noticed a number of spots on the left buttock, which were as large as pin-heads and of a white color. They then spread over both the thighs; finally exhibiting the features visible at the time the case was first seen (August 16, 1878), and at the end of a year from when they began, entirely disappeared. Three months afterward, however, the eruption again broke out, and when first examined by Dr. Hyde it presented the following appearances: The integument of the trunk, buttocks, thighs, legs (to the tips of the toes), and, to a slight extent, the hands, was covered with bodies which looked like papula-pustules, but which were found to contain neither pus, serum, nor any other fluid. The newer lesions were of a dead whitish hue, and resembled miliums in their general appearance, while the older ones were of a delicate crimson. All, however, possessed the waxy white summit which was the distinguishing characteristic of the eruption. They involved the entire thickness of the integument, and were surrounded by perfectly healthy skin. By January, 1878, the lesions had almost disappeared; but as the warm weather came on in the following spring, there was a well-marked recurrence of the trouble. During the present season, however, the patient had been entirely free from the disease.

Owing to certain circumstances which Dr. Hyde explained, no microscopical examinations of the lesions were made. The writer discussed the probability of the affections being atelangiectasic or a lymphangiomatic growth, and expressed the opinion that the diagnosis was by no means an easy one. After referring to various authorities and particularly mentioning Hutchinson's cases of *molluscum contagiosum*, he quoted a letter which he had received from Prof. Kaposi, of Vienna, in reply to one of his own describing the case, and said that in deference to the views stated therein he had concluded that it was probably one of *molluscum verrucosum*. At the conclusion of the paper Dr. Hyde exhibited a painting of the back, buttocks, and posterior aspect of the thighs of this patient, and the eruption was seen to present a very striking resemblance to that of small-pox.

Dr. Hyde also stated that under the finger the lesions felt very much like the variolous papule before the stage of pustulation.

DR. ATKINSON mentioned a case of probably similar character which he had met with in the person of a young mulatto woman. Unfortunately, however, the patient had almost immediately passed from observation.

THURSDAY, AUGUST 28TH.—THIRD DAY.—MORNING SESSION.

The first paper read was by DR. WHITE, on

ETIOLOGY.

In opposition to many of the primitive beliefs handed down from former generations and still prevalent in the minds not only of the laity, but a considerable part of the profession, as well as to many erroneous theories of more recent origin, the writer urged the following points with great force:

1. The autonomy of the skin, or its inherent right to diseased action.
2. That the pathological processes found in the skin were identical with those met with in other parts of the system.

3. That the same methods of observation and induction which were employed in the investigation of disease in all other portions of the body were equally applicable to the skin also.

In his criticism of various unfounded opinions (according to his views), the writer scouted the idea of diathesis, as advocated by the French school of dermatologists, and the whole tone of the paper was strongly in support of the local, rather than the internal origin of diseases of the skin. It was followed by a prolonged and animated discussion, which was participated in by Drs. Heitzman, Fox, Sherwell, Taylor, Bulkley, Hyde, Wigglesworth, Van Harlingen, and Hardaway.

The next paper was one by DR. R. W. TAYLOR, of New York, on

THE NATURE OF SYPHILIS.

In the first part of it he took up in turn the various terms which have been employed by different authorities to express the nosological relations of syphilis, and pointed out to what extent they were all incorrect and unsatisfactory.

The remainder of the paper was devoted to a statement of his own views, as follows: Our own conclusion is that syphilis is a disease of the connective tissue, and not primarily of the lymphatics or of the blood-vessels, although the blood may be temporarily modified and may be the vehicle of contagion.

The secretions of syphilitic lesions are found to consist of a serous fluid containing numerous shining granules or molecules, which are masses of protoplasm or germinal matter, holding the contagious properties of syphilis. These microscopic bodies are probably taken into the circulation by the lymphatics and conveyed over the body. Possibly they are absorbed by the blood-corpuscles, or the latter are infected in some mysterious manner by these actively increasing morbid cells. The fact that serum alone does not convey the syphilitic poison goes to prove that the corpuscles hold the contagious material.

In the secondary period of syphilis these cells are very numerous, and the body may be covered with papules and tubercles composed of them. As the disease wanes, these lesions become more localized and fewer in number, and the blood is less contagious. Finally these cells may be limited to a few gummy tumors; the blood no longer carries the molecules, and it loses its contagious properties. The cells no longer have a tendency to reproduction, which characterizes them in the early stages, but rather degenerate. Hence we consider the blood and secretions in tertiary syphilis innocuous. Even if cells are present, they are old and inactive, and are incapable of reproducing themselves. Lancereux states that he has often punctured himself in making autopsies on subjects with gummy tumors, and has never seen any bad result.

The periods of latency observed in the course of syphilis are of interest, and may perhaps be explained in the following way: Each outburst is attended by the development and multiplication of the peculiar cells, which run their course and are finally absorbed. Some remain, and after a time are excited by unknown causes to activity. Thus repeated exacerbations may recur, each one depending upon the multiplication of cells remaining from a previous outburst. But each relapse is less active and less prolonged than its predecessor, until perhaps only one nodule, and that composed of effete cells, may remain. The disease is then cured. This explanation may seem to apply imperfectly to those cases of prolonged latency

in which no lesion whatever has been perceptible. Virchow thinks that in these cases the lymphatic ganglia have been the places of deposit of the syphilitic cells, which, at the expiration of the period of latency, undergo the changes mentioned. In any case, the specific cells must be hidden away somewhere in the system, since the continuance of the disease depends upon their existence.

With this view of the nature of syphilis, its effect upon the health and upon the organs and tissues may be readily comprehended. In the early active stage of proliferation the red globules are diminished and the white increased in number. The depressing influence of syphilis is thus fully accounted for. Digestion is impaired and the tissues are poorly nourished. Finally, the functions of vital organs may be perverted, or destroyed by the cell-changes produced.

DR. ATKINSON said that he was somewhat surprised that Dr. Taylor should speak of a specific cell. He believed that in nature only a certain kind of cells would be found under any circumstances, and he did not see how it was possible that any different ones should be formed. Neither could he imagine a condition in which the cells referred to by the writer should become so old as not to be reproductive, if they were alive at all.

DR. HEITZMAN thought that too much was assumed in the paper, and not enough proof given in support of the statements made. Let us demonstrate what syphilis is, said he, and then we can form any number of hypotheses.

In reply to the latter, DR. TAYLOR remarked that all the points stated by him had been substantiated by the careful microscopical investigations of Lancereux, Wagner, and a host of other distinguished authorities.

The last paper was by DR. HARDAWAY, on

A SIMPLE METHOD OF OBSTRUCTING THE VARICOSE VESSELS IN ROSACEA.

The procedure recommended was essentially the same as that described by Dr. Hardaway in his paper, presented last year, on the removal of superfluous hairs. Electrolysis, by means of a fine needle (No. 13 cambric), was the agency employed; the only difference being that it was unnecessary to introduce the needle to such a depth, or keep it in the tissues so long, as when the aim was destruction of a hair papilla. Six or eight cells of a moderately good battery were sufficient, and a few seconds all the time that was required for the operation. If the vessel was a long one, however, two or more punctures along its course were required. When a small needle, like that recommended, was used, the parts presented no abnormal appearance whatever afterward, and no cicatrix remained. Dr. Hardaway had performed the operation successfully in several cases, but he could not speak with any great confidence of it as yet, although he felt thoroughly convinced in his own mind that it would prove of great service. His principal object in bringing the matter before the Association, however, was to induce the other members to make a trial of it when they had the opportunity.

With a discussion on the paper by Drs. White, Wigglesworth, Hyde, Sherwell, and Bulkley, the scientific proceedings were brought to a close.

On motion of Dr. WHITE, a vote of thanks was tendered the retiring Secretary, Dr. Taylor, for the efficient manner in which he had performed the duties connected with the position, and the satisfactory and comfortable arrangements which he had made

for the meetings and the accommodation of the members during the last two years.

In a few concluding remarks the President, Dr. DUHRING, congratulated the Association on the great success of the meeting just brought to a close. The papers, he said, had been able and the discussion most interesting and profitable, while the sessions were completely harmonious throughout. He was deeply conscious of the high honor which had been conferred upon him in electing him to the presidency a second time, and he could only say that in the year to come he would do all that he could to promote the interests of the Association and to render it as useful an organization as possible.

The Association then adjourned to meet at Newport on the last Tuesday of August, 1880. In the afternoon a clinical meeting was held at the New York Hospital, for the examination of various cases of interest that were presented by the members from New York and Brooklyn.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 11th, 1879.

DR. J. W. HOWE, VICE-PRESIDENT, IN THE CHAIR.

(Continued from page 212.)

FIBROUS TUMOR OF THE UTERUS.

DR. FINNELL presented a uterus, to which was attached one large and several small fibroid tumors. The large one was attached to the fundus, and all were subperitoneal. The entire mass weighed four pounds. The uterus measured five inches in length. The os was normal, and indicated that the woman had never borne children. The large tumor was calcified.

The specimen was removed from the body of a woman 58 years of age, who had been gagged and murdered at her residence in Forty-second Street of this city.

The brain, lungs, kidneys, and other organs were apparently healthy, with the exception of a moderate degree of congestion. The lungs were slightly œdematous. There were no blood extravasations in either the brain or the lungs. It was thought that she died from suffocation. The right side of the heart was empty, and all the valves were healthy.

FIBROUS TUMOR OF THE UTERUS—CYST OF THE RIGHT OVARY—CYSTIC DEGENERATION OF THE LEFT KIDNEY.

DR. LEO presented a fibroma of the uterus, a cystic ovary and a cystic kidney removed from the body of a woman 48 years of age, who was a patient in the service of Dr. Blumenthal in one of our public institutions. The patient first began to complain last December, when she had pain in the region of the kidney and other symptoms, and passed only about twelve or fourteen ounces of moderately albuminous urine daily. Not long after she had considerable œdema of the lower extremities, and a month later still there was distention of the abdomen, which increased steadily. Dr. Blumenthal then made a diagnosis of fibroma of the uterus, and thought there was also other disease present.

The case progressed from bad to worse, the abdominal distention increasing, diaphragmatic respiration became seriously impeded, threatening asphyxia developed, and upon consultation the abdomen was

aspirated, and four or five gallons of fluid drawn off. It was examined microscopically and spectroscopically, but with only negative results. An additional gallon of fluid discharged spontaneously. The wound closed, the peritonitis continued for about twelve days, and finally subsided with every indication of recovery. Suddenly the urine became excessively albuminous, sp. gr. 1030. Uræmia developed, and death occurred two days ago.

At autopsy a fibroid tumor was found attached to the uterus, and there was also a cyst of both ovaries. The right kidney was also cystic; but it was impossible to remove the kidneys on account of excessive softening and fatty degeneration.

An interesting point in treatment was that neither of the cysts was punctured when the abdomen was aspirated. The cysts each contained about a pint and a half of fluid, and there was besides about one gallon of fluid in the abdominal cavity. It was evident to Dr. Leo that the ascites was produced by mechanical pressure.

DR. BLUMENTHAL remarked that the patient was an unmarried woman, who, until six months ago, had enjoyed comparatively good health. It was not until her ovarian trouble developed that she began to complain. The cysts were not sufficiently large to account for the distention of the abdomen, and it was evident that there was, in addition, ascites. Aspiration was performed with the view of relieving the symptoms developed by the immense abdominal distention, such as difficulty of respiration, and not with the view of tapping the ovarian cysts. As far as direct results were concerned, the aspiration was successful, for the difficulty of respiration was relieved. An operation for the relief of the ovarian disease was contemplated, but was prevented by the death of the patient. The autopsy, however, revealed a condition which would have rendered an operation impossible.

FLESH MOLE.

DR. HEITZMAN presented what was sometimes called a flesh mole, or a placenta, in this instance in the fourth month of pregnancy, occurring in a patient of Dr. L. Weber. Microscopical examination revealed the presence of fat with only a small amount of the original placental tissue remaining. Almost the entire tissue had been replaced by hemorrhagic clots. The remaining deciduous portion had undergone extensive waxy degeneration.

VILLOUS MOLE.

Dr. Heitzman also presented what he denominated a villous mole, or a placenta, that had been entirely transformed into pedunculated berry-shaped masses. Microscopical examination revealed that these little bodies were cysts which contained blood, not in a fresh condition, but coagulated fibrin, and blood-corpuscles that were somewhat disintegrated. There was no evidence of waxy degeneration. The question arose whether such a villous condition could not be the starting-point of a future cystic mole.

Dr. Heitzman also presented a six-weeks' placenta with embryo in place, that had been brought to him by Dr. C. A. Loring. The entire placenta exhibited a yellow color, and had the appearance of fatty degeneration. Dr. Loring also expressed the opinion that it was probably fatty. But in that, as in others, the microscope revealed waxy degeneration of almost the entire solid part of the organ. The villous portion had also undergone waxy change.

With reference to the specimen of placenta presented by Dr. Putnam-Jacobi at the last Stated Meet-

ing of the Society, Dr. Heitzman remarked that it also had undergone marked waxy change.

There were doubtless protoplasmatic bodies in the decidua which were scattered globules of fat, but the fatty change was so slight in comparison with the large mass of homogeneous shining material, that he did not hesitate to say the principal degeneration was waxy in character.

The Society then adjourned.

Correspondence.

THE EXPERIENCES OF A SUCCESSFUL PRACTITIONER.

II.

WHEN Mr. Smith urged me to see his child, after my consultation with Dr. White, I told him that I could not do so because Dr. W. was the regular attendant. Besides, I was overrun with work, and it was but fair that Dr. W. should have a start and make a living. I further said that I appreciated the feelings of a father who was anxious about his son, but, under the Code, I was forbidden to help him out of what he believed to be his difficulty. My assurance that the child would probably recover did not comfort him much; neither did he seem satisfied when I informed him that I would from time to time give Dr. W. such hints as occurred to me, as Dr. W. generally consulted me privately about his difficult cases. Such a trait, in my opinion, recommended him as a young man who was conscientious to his patients, and not afraid nor ashamed to learn.

Just then Dr. White dropped in the office and was somewhat surprised to see Smith and I in conference. Smith was, however, astonished, and for the moment did not know what to do. This gave me my opportunity to put both at their ease by saying that Mr. S. was naturally much worried about his child, and not knowing anything about the Code, had dropped in to talk over the case, and that I had comforted him by telling him that Dr. W. was just the man for the case, and that it was not proper for me to interfere by word or act. Dr. White was pleased, and the ice was broken for a general conversation. The latter ended by my promise to be present at a consultation on the morrow. After Smith left, Dr. W. and I had a frank conversation upon the proper relations which should exist between patient and physician, and between each other; at the same time he intimated that Smith seemed to be a little dissatisfied. White did not believe in keeping cases against the will of the patient, and became virtuously indignant at the want of confidence in him. So incensed did he seem that I was fearful that he might give up the case at once. However, I coaxed him to hold on and he finally left in good humor.

The following day I arrived at the patient's house before Dr. White, and waited for him at the bedside. While so doing I learned that Harry had three passages since the night before and was worse. The mother then showed me the medicine that Dr. W. had ordered. I said that there must be some mistake; that in fact the remedy was the same as the child had been taking when I called, and signified my desire to see the new medicine. When informed that the mixture was made by Dr. W. since the consultation, I at once smiled and changed the subject. The mistake

arose from the fact that Dr. W. had repeated the rhubarb and soda instead of using the chalk mixture. Although this annoyed me somewhat, I merely remarked that Dr. W. must have misunderstood me; that the medicine should be white instead of red, and that I would explain the matter to him when he came. In the course of the conversation I learned that each time after partaking of the medicine the child became worse, but I merely said that she could stop giving the remedy, and that we would make it right when the doctor arrived. Just then he came in. I had the bottle of medicine in my hand, and apologized for my apparent interference by remarking to him that he had misunderstood me, and that the child appeared to be worse. He blushed somewhat, and said that he had none of my medicine with him at the time; a remark which was very indiscreet in presence of an anxious parent. However, I said that as I carried it around with me always and used it a great deal, I would give him some. Accordingly I made the mixture on the spot, administered it to the boy, and retired to consult. White agreed to continue with the chalk mixture, and, when we returned, the boy said he felt good, wanted to sit up, and said he was hungry. I playfully remarked that he liked his medicine, and that he was getting better already. Dr. W. smiled also, and the mother seemed to be quite happy. Shaking hands with little Harry and patting his head, I took my leave, saying that the doctor had done everything necessary, and that I had nothing more to suggest. We left together. W. apologized for not using the chalk mixture the day before. I told him that it was a small matter, but was on my part sorry that I had alluded to the fact before the mother. The next morning White called on me to say that, although the child had improved the family had dismissed him, and urged me to see the case. I felt very delicate about the matter, but as I knew that my former partner would be called in, and as Dr. W. and the family were both willing, I consented, if sent for, to see the case through. After coming to such a conclusion, Dr. W. thanked me for what I had done for him, and assured me that he was willing to leave himself and his former case in my hands. Harry recovered in a day or two, but all I can do I cannot persuade the mother to employ Dr. W. any more. Can I do more?

I have often tried to impress upon Dr. W. the importance of humoring his patients, and have many a time told him that he was too dogmatic. On several occasions I have been placed in an apparently false position by his obstinacy. To give an instance: A wealthy gentleman from the city built a fine mansion in the village and came with a letter of introduction from a college professor to Dr. White. Dr. W., of course, had the family. I was glad to hear of his good luck, especially as the wife of the gentleman was an invalid, and required a great deal of attention. One day on driving past I was hailed by the servant, who asked me to step in and see his mistress. I obeyed the summons, and found a delicate lady reclining upon a lounge, complaining of a ball in her throat, great oppression in breathing, great pain in left side, and a desire to urinate frequently. She informed me that she was Dr. White's patient, but was somewhat discouraged with his treatment. I at once told her that Dr. White was a splendid fellow, one who had a great opportunity for working out her case; that although he had but few patients, he loved to study, and was, on the whole, a very safe, if not too cautious, a practitioner. But this did not quiet her pain. She said that Dr. W. had not only left her

medicine which made her worse, but that he had insisted upon her taking it in spite of the pain. I asked her, with honest incredulity upon my countenance, whether he actually said so. I tasted the medicine and repeated the question with a like answer. Being then assured that there was no mistake, I said that he was probably right, but that she had better not take any more of the medicine until I saw Dr. W. She then seemed better satisfied. I found, on questioning her, that Dr. W. had not made any vaginal examination, nor had he hinted at any. Some way or other she squeezed out of me an opinion that her whole trouble was uterine, and that an examination was necessary. I think I told her as much before I knew whether or no White had expressed any opinion. At all events to humor her, I examined her on the spot and discovered an abrasion of the os. I promised her that I would tell Dr. W. about it and left her without any further suggestion. Now W. is one of those stubborn chaps who do not believe in abrasions, but I tell him almost every woman has them, or ought to have them, and he will be always safe in a diagnosis. He informed me that he did not intend to humor such a prejudice on the part of his patient and seemed a little angry. In spite of all I could do when the husband of the lady sent for me to attend her, I could not persuade her that White was of the two doctors the better man. This case, by the way, narrowly escaped going to my partner, who is a uterine man, and who is favorably known among the laity as the inventor of a self-entering, self-retaining, back-action speculum. I do not think much of his instrument, however, as I have invented one of my own. It is needless to say that the case progressed favorably, and I secured a good fee. It might just as well have gone to Dr. W., but I did the best I could for him as a professional brother. The result of this case was published in our town paper, but as I was Chairman of the Committee of Ethics of our County Society, I explained the case satisfactorily.

Although I have gone somewhat in detail regarding the matter of this epistle, it has been my desire to show that with every appearance of having actually stolen patients from Dr. W., I did everything I could, "under the Code," to protect and befriend him. And yet there are some who say that there is no necessity for a code. * * *

PINK RIDGE ON THE HUDSON.

CHOLERA IN JAPAN.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The cholera epidemic which we reported last mail as severe in the southern provinces of this empire, has at last crossed the mountain barrier which separates them from the capital and the northern half of the island of Nipon.

Though the daily number of cases in Yokohama and Tokio are as yet few compared with that reached in the cities of Kobe and Osaka in June and July, there is still time for sad havoc before the cold weather sets in. The returns up to the 25th of July, from the infected localities referred to, show a total of 31,759 cases, 18,017 deaths, 3,731 cured, 10,011 under treatment. The daily number of cases in Yokohama at this date average from 15 to 20, with a mortality rate of about 50 per cent. The majority of these are received in a well-constructed pavilion hospital of 100 beds. The energy displayed by this people, to whom systematic treatment of epidemic diseases is nearly new in the use of the most improved

means of combating the spread of this scourge, is truly wonderful. We shall have occasion to speak of this in our report at the close of the year.

A detention quarantine of vessels from infected ports, which was established for a time with the hope of retarding at least the progress of the disease in this direction, has been raised, and the inspection system substituted.

D. B. SIMMONS, M.D.

YOKOHAMA, August 12, 1879.

TREATMENT OF YELLOW FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Notwithstanding the many communications regarding yellow fever, I cannot help writing a few lines in reference to an article in issue of RECORD August 16, 1879, where attention is called to the helplessness of physicians in the treatment of yellow fever of the past year. It is much to be regretted that our therapeutics is not more efficient; but, like all epidemics of the severer type, the same want of success will apply. This certainly holds good in the strongest sense in cholera, and yet there is no better field in the world than that which the army surgeons of India have for the study and the treatment of the disease. Every variety of treatment has been tried, and what has been apparently very successful in one year or one section, has been quite the reverse another season; this holds good with other diseases, and especially with yellow fever. Every year brings out some new treatment, to be again thrown aside next year as no more reliable, and as unproductive of good as the preceding. There is no question about the pathological condition being one of congestion—that is, one of the factors of the case, but one only. Watch the disease thirty or forty years, and the pathological condition will be an enigma. While the experiments of Dr. Leared are interesting, I can see no analogy between the cases mentioned and those affected with yellow fever. In the latter the blood is frequently thick and sluggish, having apparently lost its more fluid parts, and excessive sweating is not likely to replace it. In the treatment of yellow fever the induction of diaphoresis is an early desideratum, and is promoted by hot mustard pediluvium, warm teas, etc., bricks made warm, wrapped in flannel and sprinkled with alcohol, vinegar, etc. But those measures do not shorten the fever that runs its course while free sweating is progressing; but carry this to excess, which seems to be relied upon, and the patient's strength is exhausted, and there is not left the recuperative powers necessary to convalescence, and I cannot but think the excessive sweating induced by the Turkish bath, so far from relieving, would in fact have the tendency of inducing congestion of the brain. I have, in fact, witnessed cases where excessive sweating has been a strong factor in the cause of death. I would give cases, but this paper is now more than I expected to write.

CONTROL OF PATIENT'S TONGUE DURING LARYNGOSCOPIC OPERATIONS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—During the past three years, and while engaged in the throat department of an extensive clinic, the writer has dispensed with any assistance from patients in holding or controlling the tongue during laryngoscopic operations.

By exercise and training of the fingers of the left hand it is not difficult for the operator to control the tongue, and at the same time to hold the throat-mirror in position with these fingers.

The manœuvre, as practised by the writer, is as follows: The throat-mirror, heated, is held in the right hand; the tongue is grasped with and between the ring and little fingers of the left hand; the mirror is then placed in position and held between the thumb, index, and middle fingers (of the same hand), precisely as a cataract knife is held during operation.

As there is naturally little strength of grasp or unity of action between the ring and little fingers, some exercise and practice of these digits will be required so as to enable them to hold the tongue.

The ability to use the fingers in the manner indicated will of course give the operator the great advantage of having his right hand free for the use of instruments.

MICHAEL C. O'TOOLE, M.D.,

Late Demonstrator of Laryngoscopy and Diseases of the Throat, Medical College of the Pacific.

SAN FRANCISCO, CAL.

NOTE ON EPILEPSY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In your last issue, Dr. Tanner, U.S.A., communicates notes of a case of epilepsy treated by means of a mixture of chloral and bromide of potassium. This plan is excellent, and has been put to a thorough trial in this city by Dr. A. McL. Hamilton, Dr. McBride, and myself. I now frequently employ such a mixture. Dr. Tanner will find all about this mode of treatment in various numbers of the *N. Y. Medical Journal* for 1878-9, under the title of "Proceedings of the New York Therapeutical Society."

Yours truly,

E. C. SEGUIN, M.D.

NEW YORK, Sept. 1, 1879.

New Instruments.

URETHRAL DILATOR AND SPECULUM.

By ALEX. W. STEIN, M.D.,

SURGEON TO CHARITY HOSPITAL, ETC.

DILATATION of the female urethra is an operation justly esteemed of great service not only for purposes of diagnosis and exploration, but for the treatment of urethral and vesical diseases of the female. But I believe I can assert that the instruments we have hitherto employed for this purpose are not satisfactory, too often rude, faulty in construction, and dangerous. With this conviction I have had constructed a dilator perfectly simple of manipulation, effective and safe, and which I think will be found a decided improvement upon instruments of a similar nature. It consists (see Fig. 1) of a metal tube, three and a half inches in length, with an obturator, elastic

and conical at the point which projects an additional inch beyond distal end, and which serves to facilitate the introduction of the instrument. One inch from proximal end (at A, Fig. 1) is a handle which supports a graduated bar and screw, by means of which the expansion of the instrument is effected. When closed it is thirty-three millimeters in circumference, and is capable of expansion to fifty millimetres. Fig. 2 represents a section of the instrument in a state of complete expansion.

The value of this instrument can only be appreciated when put to the test. Nevertheless, I trust its utility will be sufficiently apparent from description to invite for it a trial. It will be seen that the expansive force of the instrument is exerted equally and simultaneously on all parts of the circumference of the urethra, and not upon two or three points or sides of the canal, as with the instruments usually employed in urethral dilatation. Furthermore, the dilatation can be effected very gradually and with great precision, the degree of expansion of the instrument being determined with the greatest accuracy, even to a millimetre. The canal is stretched

one or more millimetres at a time, according to the amount of resistance felt, allowing sufficient interval of time to elapse for the tissues to relax. In this manner we conform to the conditions by which alone a maximum degree of dilatation without laceration can be attained. Indeed, the tearing or rupturing of the urethra, which, with the ordinary instruments employed, is the almost inevitable result when thorough dilatation has been made, and the troubles of incontinence of urine, etc., which such an injury often entails, are entirely avoided. Owing to the peculiar conformation of the instrument it creates very little pain even when dilated to its utmost.

A most satisfactory view of the urethra and bladder can be obtained either by means of the endoscope which can be attached to the speculum, or by means of the ordinary reflecting mirror.

Tiemann & Co., from whom the urethral dilator and speculum can be obtained, will adapt the same principle of mechanism to other dilating instruments.

CHANGE OF NAME.—The name "Louisville Medical News" has been changed, and the first number of the next volume of the journal will appear with the name "The Medical Age." We hope this racy journal may be successful under its new flag, but there is nothing that so comes home as the old flag under which we were born. If the worthy editors can protect their names from *orthographical* mutilations, we see no reason why their prosperity will not be heightened. In the event of such a calamity, we must beg leave to place them under the watchful care of the editor of the *Michigan Medical News*.

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis, from Sept. 3d to Sept. 9th, inclusive, was 153, and the number of deaths that occurred was 62. The total number of cases for this year to Sept. 10th is 1095, and the total number of deaths, 332.

DR. CLEMENT A. FINLEY, Ex-Surgeon General of the United States Army, died at his residence in Philadelphia, Monday, Sept. 8th, in the eighty-second year of his age.

THE FOOCOW OPIUM ASYLUM.—In the eighth report (1879) of the Foochow Medical Missionary Hospital can be found the first report of "the Opium Asylum," under the care of Dauphin W. Osgood, M.D.

The following are the most important and interesting portions of the report:

"Since the publication of the last Hospital Report, the Opium Asylum has been conducted as a separate establishment, and has been self-supporting. The number of patients treated has been five hundred and forty-four; of these, twenty-four absconded and the remainder were cured.

The plan of treatment consists in the total discontinuance of opium in any form from the time of entering the asylum, and in administering chloral hydrate and potassium bromide for the first three or four days as required. A pill consisting of extract of belladonna, gentian, valerian, quinine, and ginger, is given morning and evening. In addition to the above, various complications have to be met as they occur, such as diarrhoea and vomiting. In some cases stimulants are required, and in all, good food that is easily digested should be taken every three or four hours in small quantities.

In all, over 1,100 cases have been treated. As a majority of these cases have come under my personal supervision day after day, I hope that I shall not be accused of egotism or cant when I write that in my opinion the use of opium is an unmitigated curse. It is equally true that rich and poor alike suffer from the continued use of the drug. It causes anorexia, indigestion, constipation, a general loss of vitality, anæmia, and in many cases difficulty in breathing. The confirmed smoker usually becomes impotent. His sallow skin, emaciated form, and languid step, tell the story. I am free to admit that there are cases where opium is used constantly for twenty or even thirty years in small quantities, with comparatively little injury to the user, but these cases are the exception and not the rule. It is also true that a given amount of opium smoked is less injurious than when swallowed. *I have never yet heard a heathen*

Chinaman defend the use or sale of opium, but on the contrary they universally condemn them. The only apologists for the use of opium have been representatives of Christian lands, many of which have had but little practical knowledge of the evil resulting from the use of opium. We append a table giving statistics of 1,000 opium patients, showing their occupation and the amount used, etc.

Farmers, 273; Literati, 83; Officials, 5; Shop-keepers, 304; Mechanics, 43; Buddhist priests, 2; Taoist priests, 3; Soldiers, 17; Carpenters, 23; Bamboo-workers, 16; Tailors, 22; Attendants in opium shops, 8; Brokers, 6; Doctors, 5; Miscellaneous, 190.

Number treated under twenty years of age.....	5
From twenty to thirty years of age.....	203
“ thirty to forty “ “	454
“ forty to fifty “ “	261
“ fifty to sixty “ “	68
“ sixty to seventy “ “	9
The number using from one candreen to one mace.....	51
From one mace to a mace and one-half.....	89
“ one and one-half to two mace.....	187
“ two to three mace.....	317

“ four to five “	77
“ five to six “	36
“ six to seven “	16
“ seven to eight “	5
“ eight to nine “	8
One ounce.....	3

Fifteen eat opium instead of smoking it. The amount used ranged from five candareens to three mace of the prepared opium.

As some of our readers are not familiar with Chinese weights, we may say the ounce is divided into ten mace, and the mace is again divided into ten candareens. The ounce is equal to 38 grammes.

The above-mentioned quantities are of the extract of opium; each ounce of the extract is said to represent one and a half ounces of the crude opium.

Number who had used opium less than five years.	232

“ “ “ ten to fifteen.....	251
“ “ “ fifteen to twenty... ..	94
“ “ “ twenty years & more.	103
“ “ “ thirty years.....	7
“ “ “ thirty-five years....	1
“ “ “ forty years.....	1

Among the patients there was a Buddhist priest who smoked an ounce of opium daily. He remained about ten days, and at the time of his discharge said that he had no desire for opium.

Another case of interest was that of a military officer, a native of Hunan. He had used opium for more than twenty years, and at the time of entering the asylum was unable to attend to his duties. He had anorexia and constipation, was emaciated, and the slightest exertion caused difficulty in breathing. He had a severe time getting cured. For several days was unable to sit up in bed, but finally got over his desire for opium, and his general health was improving when he left. Before he left Foochow he presented a nice tablet to the Hospital, abounding in eulogistic sentiments.

THE RHODE ISLAND MEDICAL SOCIETY holds its quarterly meeting in Providence, Wednesday, Sept. 17th, beginning at 10 A.M. W. E. Anthony, Secretary.

THE NEW HAMPSHIRE MEDICAL SOCIETY holds its semi-annual meeting in the city of Hanover, Sept. 17th and 18th, 1879. G. P. Conn, of Concord, Secretary.

Original Lectures.

FIBROID TUMORS OF THE WOMB.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL
OF THE UNIVERSITY OF PENNSYLVANIA,

By WILLIAM GOODELL, A.M., M.D.,

PROFESSOR OF CLINICAL AND DIDACTIC GYNECOLOGY IN THE
MEDICAL DEPARTMENT.

Reported for the MEDICAL RECORD.

By the word polypus we mean a stalked tumor growing from the inside of the womb. A fibroid tumor is a tumor without a stalk, having its origin either on the surface or in the substance of the womb. A fibroid tumor growing on the peritoneal surface of the womb may have a pedicle, but in that case it would not be called a polypus. When a pedunculated tumor projects from the cavity of the womb, as is often the case, it is known as a polypus.

CASE I.—This patient that I shall bring before you is sterile. She has been married for a number of years. Soon after her marriage a very curious circumstance occurred. She fancied that she was in the family way, and, the hour of supposed confinement drawing nigh, a physician was summoned, but no child was born. The disappointment preyed considerably on her mind. We all know how great is the pride of maternity. Soon after she came to the Retreat, of which I have charge, for a child, and adopted one. I afterwards learned that she again went regularly to bed, sent for a female physician, who was in the secret, and was ostensibly delivered of this adopted child. This was done to save her wounded pride, for her relatives thought she would otherwise become insane. Unfortunately the child did not live long.

Last week the woman came to see me at the Retreat, saying that she had been flooding a great deal of late, and was rapidly growing fat. Why was she getting fat? The blood-corpuscles, as we know, are the oxygen-carriers, or consumers of the surplus fat of the body, and it stands to reason that, when their number is decreased by hemorrhage, the fat will accumulate. This fat is, of course, of a very low grade.

As the patient had not been in the hands of any physician, and as the existence of some foreign growth in the womb was suspected, I prepared the way for an examination by the introduction of some spongetents. These I removed in twenty-four hours, and filled their places by six new ones. The cervix is today sufficiently enlarged for me to introduce my finger with ease, and what do I find? The cavity of the womb is pretty well filled up by a large tumor. I succeed in grasping it with this instrument, and am bringing it out piecemeal. The growth cannot be a simple fibroid tumor; for it breaks down so readily under the traction that I fear microscopical examination may prove it to be a sarcoma.

Growths of this nature are very likely to lead physicians to false conclusions. The sound is introduced by the medical adviser, and, impinging upon the tumor, prevents him from obtaining the actual length of the womb, and he thinks no growth is there.

As I said a moment or so ago, I am very much afraid that this growth will prove to be a round-celled sarcoma. It breaks down entirely too easily for a simple fibroid, and there is no evidence of necrosis. A round-celled sarcoma is a tumor, without a capsule, feeling like placental tissue. It is a very rare growth

as originating in the womb. This is only the fourth case of the kind that has come under my observation.

I will now curette the wall of the womb, and see if some more fragments will not come away. Crumbling tumors are always dangerous. The round-celled sarcoma, in particular, is very malignant, almost always returning, and, in the end, destroying life. The sarcoma is not, however, so rapid in its course as the carcinoma. In this case there is no pedicle, the growth coming from a large uterine surface.

Once upon a time, many years ago, I was decoyed into a bad error of diagnosis. The case happened to be my first one. I was called to see a woman with a uterine tumor, which had been twice removed, but had as often returned. From this history I inferred that this return of the growth was owing to the fact that the tumor had not been entirely removed upon the previous occasions. I made a digital examination, and found some projecting body, which I made up my mind was a polypus. Upon endeavoring to remove it, this growth broke down so much that I had to use a curette. Subsequent events showed me that what seemed to be the polypus was a sarcoma, and that what I had imagined was the pedicle was tissue constricted by the os.

But to return to the present case. I feel a small remnant of the growth on the posterior wall of the womb. This I will not remove to-day. It is apparently, upon more careful examination, a second small fibroid about the size of a hickory-nut. All the other vestiges I have succeeded in scraping away. This small fibroid which is left is so slightly projecting that there is no chance of removing it.

I will have the fragments which have been scraped away carefully examined. If it turns out to be a round-celled sarcoma it is sure to return. I say that this diseased growth always returns, and yet I have met with an apparent exception. Three years ago I was called by a friend to see a patient of his—a woman—the wife of a truck-farmer near Philadelphia, who, at the age of sixty-five, had begun again, as she thought, to see her courses. We made an examination, and found what we supposed to be a round-celled sarcoma, and removed it, but gave a bad prognosis. Strange to say, there has been no return of the growth and no subsequent hemorrhage. We took away some of the pieces, but lost them, and so have never since been able to substantiate our conclusion. We may have both been in error.

I am injecting this woman's womb with iodine. You can all see, I think, this eversion of the lining membrane of the cervix—the so-called "arbor vita."

These tumors, as they present themselves to the practitioner, may be generally divided into three classes, viz.: (1) those which, being extruded, occupy the vagina; (2) those lying partly in the vagina and partly in the womb, and which are not hard to remove; (3) those which, being intra-uterine, are difficult to remove.

If this proves to be a round-celled sarcoma I shall next week proceed to cauterize the womb where it is diseased, with pure nitric acid.

CASE II.—Here the growth is partly in the vagina and in the womb. It is very large. The woman is unmarried. Four years ago she began to lose a great deal of blood at her monthlies. This flooding was attended with a great deal of pain, which has been growing steadily from bad to worse, until she is now greatly reduced in health. You remember that I brought her before you last week, introduced my finger, and found the vagina filled with a large tumor. This tumor may possibly be an

inverted womb, but I think that I have made such a careful examination as to preclude such a possibility. The tumor is so large that I may be obliged to use as much force in delivering it as I would in bringing down the head of a child. In view of such an emergency, I have brought with me a crotchet and a cephalotribe. The rule which I follow in the case of all tumors of the womb is to get them away by hook or by crook, to get them away as a whole or in pieces. In some cases I have been obliged to take them away piecemeal, bringing down and cutting away as much as possible at each time.

I remember a case that occurred to me some twenty years ago, in which two weeks were consumed in the removal of a growth of similar character. We had no such thing as an *écraseur* at that time, so that we were obliged to do all our work with the long-handled scissors. The first day we cut off all that we could, fully expecting copious bleeding. Fortunately there was but little. (Velpeau holds that hemorrhage is rare in such cases.) On the fifth visit we were able to reach the pedicle and remove it. If we had had an *écraseur* we might have done the whole thing at one visit.

I bring down the tumor to the vulva, and enable you to see that it is very large. So large is it that I find it impossible by any means to reach the cavity of the womb. The tumor is very offensive. The womb runs up nearly to the level of the umbilicus. I shall probably have to incise the perineum in order to get the whole tumor away. The first thing to be done is to clean out the vagina with carbolic acid. This syringing gives vent to a very offensive discharge which has been all the while imprisoned in the vagina. The tumor has acted just like the head of the child preventing the escape of the waters. I am going to deodorize this putrid discharge, as well on the woman's account as on my own. Having done this, I first try to pass a sound. I am certain that the tumor is as large as a child's head at full term. By means of this volsella I am going to try to pull the tumor down and cut it off near its base; but this I find to be impossible: the volsella won't do. I then take the obstetrical crotchet provided with a hook, and see if I can budge it; but still it resists. I must cut the perineum, as I think that it is the perineum which stands in my way. I do this cautiously, as I wish to be very careful not to tear the rectum. I am going to make a lateral incision, or rather lateral incisions—one on the right, and one on the left. I may, after all, be forced to make a slight backward incision.

I ask my assistant now to push on the womb above while I try to bring down the tumor with the guarded crotchet. I find this instrument is slipping, so I hold on to what I have already brought down with the volsella, while I pass the crotchet higher up and get another hold. I am following the proper obstetrical rule, you see, in delivering in the plane of the superior and inferior straits. I support the perineum meanwhile by hooking my finger in the rectum. I now take a second volsella, and make traction by catching the tumor below. This brings us to the pedicle, and, before proceeding to enucleate, I wish to see if the womb is inverted. I have got to be very careful here too, for this is the dangerous part of the operation; for if the womb is at all inverted, it is very difficult often to decide which is the tumor and which the womb. This is no easy question to decide. At any rate, I think this is the line of demarcation between the two, and here I shall begin the process of enucleation. This is undoubtedly the tumor proper: I am going to enucleate it with my finger, so that I may not get into the cavity of the peritoneum. After all,

you see that the tumor has no pedicle at all. I am digging the base of the tumor out of the wall of the womb, which I have inverted, and which my assistant, Dr. Taylor, is keeping inverted for me. There is always less bleeding if one is able to do this. You can see here the bands of adhesion running into the tumor which have fed and supplied it. •

I am gradually getting it all away—yes, here it all is in my hand. It is unusually large. I should say that it was originally a fibroid starting in the wall, near the mucous membrane, and that it was gradually pushed out of the wall of the womb and into its cavity, thus gradually enucleating itself. Here is its capsule, and see how readily we can remove the growth proper by incising its capsule. If there is persistent bleeding, I will apply one part of Monsel's solution to three of water to the cavity of the womb by means of a sponge; but I do not like to put foreign bodies in the womb after such an operation. I am afraid that gangrene and necrosis would follow if I used the full strength of Monsel.

I will now proceed to put in my stitches. These are more than necessary on the lateral surface. The tear on the posterior surface is only through the skin and fourchette. The womb has been entirely reinverted. The posterior tear is the same one which we meet with in almost every first labor.

I am very anxious to see this case recover without any infection or any hemorrhage.

Why are we able to deliver the tumor in such a case? Simply because we are able to invert the womb and remove the growth by enucleation. If I could not enucleate by means of my fingers, I should use a serrated spoon, or cut a groove round the base with a pair of scissors.

Sometimes we experience great difficulty in delivering the tumor. In such instances, if I were unable to bring it down I should cut off all I could with the hot wire at each visit until I had finally brought it all away. As a general thing, if circumstances are favorable, it is best to do it all at one sitting, for a raw surface is constantly discharging, and there is constant danger of blood-poisoning.

If you find a tumor occupying the cavity of the womb and cannot bring it down, how are you to act? (1) Try to twist off the pedicle. The volsella forceps is of no use in this connection, (a) because its hooks project; (b) because it has to be opened so wide that it cannot be passed far up; and (c) because it tears away when you have succeeded in catching the growth. The best instrument for this purpose is the fenestrated polypus forceps. This can be slipped into the womb and the tumor caught at hap-hazard. You catch hold of the tumor just as the surgeon seizes the stone in the bladder. (2) If you cannot twist off the growth, then adopt the plan of Dr. Kidd, of Dublin, by which you can never fail to remove a tumor. This is it: Catch hold of the anterior lip of the cervix with the volsella, and hand it to your assistant to hold; then get, yourself, a good hold of the presenting end of the tumor with a pair of volsella or polypus forceps: all you want is a good hold. Transfer this also to an assistant. Now slip the wire of the *écraseur* over this last volsella until you get to the os. Just here let me show you a wrinkle. You would naturally say, pass the wire up first. But not so: push up the tip of the *écraseur* first, and then coax the wire after, your assistant keeping up traction all the while, till it has passed above the equator of the polypus; it will then slip up to the root.

(This tumor is very large, but not so large as one which I enucleated six weeks ago.)

There is always a good deal of danger of cutting off a portion of the womb in performing this operation. So, after you have got the wire well up, push up the end of the écraseur until it meets with such resistance that it can go no further. In that way you restore the cup-shaped depression of the womb, and can tighten the wire with impunity.

The German physicians are the ones who recommend the lateral incisions where there is danger of the perineum being torn. These incisions must be sewed up immediately after the operation, otherwise they take a long time in healing. Braun, of Vienna—who is attending accoucheur to the Joseph Hospital in that city, where 6,000 women are delivered in a year, and who has consequently attended more labors than any other living man—lays it down as a rule always to make incisions where forceps are employed. This, I think, is a mistake; I say, always take the forceps off when the perineum begins to bulge.

If this woman should fall into the hands of a physician and tell him that she is a virgin, he would not believe her, for he would find all the evidences of a pretty severe labor.

I am sorry I did not stop the bleeding in this case by the use of ice, instead of employing Monsel's solution, for I fear that it may prevent the incisions made in the perineum from healing by the first intention.

The after-treatment will consist in binding the woman's legs together at the knees and keeping her quiet. If any symptom of septicæmia should arise, we shall give full doses of quinia.

Original Communications.

REPORT OF TWO CASES OF EXCISION OF THE RECTUM, WITH REMARKS.

By A. VAN DERVEER, M.D.,

PROFESSOR PRINCIPLES AND PRACTICE OF SURGERY IN ALBANY MEDICAL COLLEGE; ATTENDING SURGEON AT ALBANY AND ST. PETER'S HOSPITALS, ETC.

(Abstract of paper read at the Semi-monthly Meeting, Albany County Medical Society.)

THAT excision of the rectum is not a very difficult operation has been shown by the success of several operators. Billroth is said to have performed it sixteen times, twelve of his cases making good recoveries.

Among the first to do the operation in this section was the late Dr. March, who operated upon a female patient in 1868. She made a good recovery, living for eighteen months, and then died from a rapid return of the cancerous disease.

Dr. John B. Roberts, of Philadelphia, has contributed a valuable paper on this subject.

Of ten cases reported as operated on in this country, four are known to have died. One died seven months after operation, of what was said to be consumption; one was living sixteen months after the excision; of one, the termination is not known, and three are cured.

In a report by Schmidt, of Leipsic, out of thirty-three cases, twenty are reported cured.

CASE I.—*Removal of lower portion of rectum for villous form of carcinoma about the anus.*—Mrs. W—, aged forty, married, and the mother of four children. She has always been in fair health, and presents a good family record. In the spring of 1877, her youngest child being three years old and her men-

struation regular, she noticed an irritation about the anus, which gave her great annoyance, and at times pain. Her bowels became more constipated than usual, and she had some distress in passing urine. By June 1st she noticed a growth about the opening of the bowel, which she at the time believed to be piles, and accordingly consulted a specialist in this city for the treatment of that disease. She was now suffering much pain and itching, and was frequently compelled to take anodynes in order to get rest at night. The movement of her bowels she very much dreaded, as it gave her increased pain and distress. There was a constant moisture about the anus and perineum. The discharge was offensive, being ichorous in character, and producing an eruption about the skin of the gluteal regions.

The treatment she received gave her but little relief, and on Sept. 20, 1877, I was consulted. She now presented a pale, anxious expression of countenance, was in constant pain, her bowels being at times in a condition of diarrhœa; again they were costive, giving her greater pain. There was a loss of appetite and flesh. Her urine was in a healthy state—very little leucorrhœa. The uterus and organs of the pelvis were all in a healthy condition. No induration or inflammation of the deep or superficial inguinal glands. About the anus was a warty-like growth, looking as much like a small sun-flower as anything to which I can compare it. It extended for an inch about the anus on each side, and somewhat farther back towards the coccyx than forward on the perineum. In places the growth was ulcerated, bleeding somewhat easily upon touching. It extended posteriorly about two inches up the rectum, its boundary being well defined. The examination, made without giving an anæsthetic, gave her much pain.

Her menstrual periods were normal, and, as she expected her monthly sickness in two or three days, an operation was advised to be done as soon as she was well over it. This was readily assented to by herself and husband, her words being: "I cannot live long in this condition." She was given quinine quite promptly, and her rectum washed out each day by an injection of tepid water. Two doses of castor oil were also given. Oct. 1st, her menstruation having ceased two days previously, assisted by Drs. Snow, Perry, and my medical student, Mr. Worden, I proceeded to do the operation of excision of the rectum. Ether was given by Dr. Perry, and the patient was placed in the position for lithotomy. With the scalpel I made an elliptical incision, beginning in front of the anus, and then around on each side backward to the coccyx. With serrated scissors I continued the dissection, keeping my finger well in the vagina to protect, as much as possible, the recto-vaginal septum. The bleeding vessels were controlled by the use of Wells's artery clamp, and the time occupied in completing the removal of the diseased mass was about fifteen minutes. Ligatures were applied to eight bleeding arteries.

On careful examination, it was found we had removed more than two inches of the rectum posteriorly and only about an inch in front—in fact, at the latter point, there was evidently a part of the external sphincter muscle left, but the disease was believed to be thoroughly removed. The rectum was now brought down, and by ten stitches attached to the cutaneous surface. After this the oozing of venous blood entirely ceased. Cloths dipped in a weak solution of carbolic acid were applied, and the patient placed in bed. The shock was somewhat marked, the operation having lasted nearly an hour. She rallied from

the effects of the ether quite rapidly. Her urine was drawn in the evening by catheter, and by the aid of $\frac{1}{2}$ gr. morphine she passed a comfortable night. Temperature 6 P.M., 101; pulse, 108. The next day after the operation she expressed herself as feeling very comfortable, none of the old pain or irritation remaining. This patient made such an uninterrupted and successful recovery, that it is hardly necessary to give her daily record. Her temperature was never above 102, and that was for one day only. One point of interest in the case was, that all the stitches gave way between the third and fourth day. The ligatures were all away by the eighth day, the suppuration being quite free. The parts, however, were kept in good condition by frequent washing with carbolized water. No tendency to burrowing of pus. The quinine was continued for two weeks. On the tenth day, the bowels were moved by castor oil and injections, giving her considerable pain and causing some bleeding. The catheter was not used after the second day. At the end of the second week after the operation, the patient was put upon a mixture of liquor pernitrate of iron and Fowler's solution, and this was continued for eight months, when her color and general appearance were that of perfect health. Since the healing of the parts, she has had more or less trouble in getting her bowels to move. There has been very little tendency to diarrhœa, but the contraction about the anus is very decided, so that, in the three examinations I have since made, I could hardly introduce my little finger without giving pain to the patient.

At first, to relieve the constipation, I gave the patient Lady Webster dinner pills, and advised the daily use of the rectal bougie. The former, however, seemed to give gripping pain, or, as she expressed it, "too urgent a desire for an evacuation," while the latter was too troublesome to use for any length of time. For the past six months she has succeeded nicely in moving her bowels by the use of an enema.

At the present time, May 1, 1879, she seems in excellent health, and is free from all pain or irritation about the parts. Microscopic examination of the growth at the time of its removal showed it to be a papilliform form of carcinoma.

CASE II.—*Epithelioma of rectum—Three inches removed.*—In Feb., 1878, my friend Dr. Roscoe, of Carlisle, N. Y., brought to my office Mr. Wm. Becker, to be examined in reference to the condition of his rectum. Mr. B. gave the following history: He was a farmer, aged 58, married, and has three children, all grown and in good health. About nine years ago he first noticed his trouble, which he believed to be piles. He was treated by external applications, at times being worse, and then better, until three years since, when he had an abscess, which discharged quite freely. From that time the itching, irritation, and moisture of the parts have increased, being accompanied by sharp, lancinating pains; also at times by violent burning pains, which the patient very vividly describes. At times he would be troubled by diarrhœa; his pain, however, seemed greater when the bowels were constipated. He frequently experienced also a sensation, caused apparently by the presence of something in the lower bowel, and which he felt he must force out.

On examining the parts, I found, just within the muco-cutaneous border, an ulcerated mass extending up on the right side as far as my finger could reach. The glands in the inguinal region, however, as well as the bladder and prostate, seemed in a healthy condition. He presented a somewhat cachectic appear-

ance, loss of appetite, emaciation, etc. I advised an operation for the removal of the lower portion of the bowel, to which he readily consented. Accordingly, at his home, March 8, 1878, assisted by Drs. Roscoe, Perry, and Lowell, I did about the same operation as in Case I.

Having the catheter in the bladder, I made a complete dissection and removal of the rectum, to the extent of three inches on the right side and about two on the left. I did not, however, as in the preceding case, attempt to stitch the bowel to the skin; but, after securing the vessels, which were quite numerous, I placed a drainage-tube in the wound, applied a pad of absorbent cotton, and held all in place by a T-bandage. The cotton was removed on the second day, after which the wound was kept clean by the use of carbolized water. He made a good recovery, the ligatures being allowed to come away of themselves. Since last May he has had very good control of his bowels, though when the desire comes to go to stool he must respond at once, or there will be a partially involuntary escape of fœces. He has improved very much in health, and is free from all pain and irritation.

March 3, 1879.—Dr. Roscoe visited my office, and stated that, during the previous month, Mr. B. had noticed an enlargement in his left groin, which was hard and somewhat painful, but free from adhesions. This looks like a return of the disease, though in every other respect he seems well.

This patient took, for a long time after the operation, the mixture of pernitrate of iron and Fowler's solution, with seemingly good effect.

May 1, 1879. Mr. B. seems in excellent health, and is worried only by the indurated superficial inguinal gland in the left groin. About the rectum the parts present a healthy appearance.

I have reported these two cases, the only ones in which I have operated, not so much on account of their success, as the desire I have to add to the statistics of the operation, believing that time will demonstrate that it lies in the power of surgery to do more for these unfortunate patients than has hitherto been thought possible by many good and wise surgeons.

At the present time, while there are many favorable cases reported, yet the operation is considered as a palliative one merely. The period of immunity after operation cannot be determined. The conditions which seem to justify the operation, and which are emphasized in many of our late works on surgery, were well exhibited in my two cases—namely, the disease being epithelial in its character, limited to the walls of the intestines, not implicating the peritoneum, and the health of the patient not too seriously impaired. The fact that the greatest amount of the disease was situated toward the coccyx, made these two cases exceptionally favorable for the operation. I desire to call attention to the excellent use that can be made of the curved serrated scissors in doing this operation. It seems to me the immediate bleeding is not near so great, and that a good deal of the usual sponging is avoided.

I think there is much yet to be considered regarding the use of sutures. The principal causes of death in this operation have been pyæmia, pelvic cellulitis, and peritonitis. With this knowledge in our possession, is it not safe to do away entirely with sutures, give free exit to the wound by the aid of drainage-tube and frequent washing out, keeping the parts in an antiseptic condition, and avoid the possible danger there is in the sutures, closing the parts in such a

manner as to cause the pus to be retained, and thus most certainly produce some of the results that are known to prove fatal? I should like a fair, candid expression from the surgeons who have done this operation, as to how much service the sutures have been in holding the rectum down to the cutaneous surface, and whether if, in the majority of cases, they have not torn out before primary union could possibly occur.

DIPHTHERIA.

BY JOHN H. GILMAN, M.D.,

OF LOWELL, MASS.

(Read before the Massachusetts Medical Society.)

GENTLEMEN OF THE MASSACHUSETTS MEDICAL SOCIETY:—In responding to the invitation of your committee to read a paper at this meeting, I have ventured to select diphtheria as my subject, because the disease has lately prevailed in an epidemic form in Lowell and its vicinity. In writing upon diphtheria I do not expect to be able to offer much that is new or original, but shall, at first, give a general account of the disease, then make some observations regarding its nature, and lastly, give what experience has suggested respecting its treatment.

Dr. Aitken, in his great work on the Science and Practice of Medicine (6th ed., 1872), defines diphtheria as "A specific disease with membranous exudation on a mucous surface, generally of the mouth, fauces, and air-passages, or occasionally on a wound. The disease is attended with great prostration of vital powers. In some cases a remarkable series of nervous phenomena are apt to supervene, characterized by progressive paralysis and sometimes by fatal syncope. The disease is contagious and apt to become epidemic."

Although the name diphtheria is a modern invention of Bretonneau, the disease which we now recognize by that appropriate designation has existed under different names for centuries, if not from all antiquity; and although the Greek and Roman writers have not described its features with sufficient distinctness, its epidemics have been clearly indicated by Spanish, Italian, French, German, Swedish, British and American authors from the end of the sixteenth century to the present time. The earliest account of an epidemic that was undoubtedly diphtheria, which I have been able to find, is one which broke out in Holland in 1517. (Guy on Public Health.) It is described as an infectious inflammation of the throat, which often caused death in twenty-four hours. Those who ultimately got well recovered slowly. The disease soon passed away, but it spread beyond the limits of Holland, and certainly to Basle in Switzerland, where in the space of eight months it killed 2,000 people. Here its symptoms appear to have been better described, for we learn that the "tongue and throat were white as if covered with a mould," and part of the treatment consisted in removing this "viscous white coating" before applying remedies. Dr. John Starr, in 1749, describes, under the name of morbus stragulatorius, a disease which he says "has reigned within a few years in several parts of Cornwall with great severity." In his description we recognize diphtheria. He speaks of a "white body seen on the palate and tonsils," and gives a woodcut of a membranous cast of the larynx, trachea, and primary bronchi, which was expectorated by one of his patients. He speaks of the formation of a white membrane on a blistered cutaneous surface. Dr. Huxham, in his dissertation on Malignant Ulcerous Sore Throat (3d

ed., 1759), evidently confounds together the two diseases, scarlet-fever and diphtheria. We recognize diphtheria in his description of "ash-colored spots on the tonsils, uvula, palate and pharynx," and in the noisy breathing "resulting from extension of the disease to the windpipe." He speaks of the "discharge from the nostrils as being so acrid that it excoriated the lips and hands of the patients," showing the extension of the disease to the nasal cavity. In 1765 Dr. Home published his treatise on the Nature, Cause and Treatment of Croup. He was the first to describe a membrane lining the air-passages as the essential anatomical character of croup. A careful study of his cases shows that under the name of croup he included two different diseases—simple laryngitis and diphtheria. Dr. Samuel Bard, in 1771, published an admirable description of diphtheria under the title of Angina Suffocativa, or Sore Throat Distemper, as it appeared in New York. He speaks of a "membrane on the tonsils" as being frequently, but not invariably, present. He describes the formation of a membrane on the abraded skin; and he recognizes the infectiousness of the disease, but rather "from the breath of the infected person" than "from any prevailing disposition of the air." And this, he says, explains the fact that a whole family may suffer from the disease, while the next-door neighbors escape. He speaks of one family in which seven cases occurred, three of which were fatal. Cullen, in his First Lines of the Practice of Physic (4th ed., 1784), under the head of Cynanche Maligna evidently includes scarlatina anginosa, and diphtheria. The latter is indicated by the appearance of white or ash-colored spots on the fauces. Mr. Henry Rumsey, in Account of Croup as it appeared in the Town of Chesham in Buckinghamshire in 1793-94, says that "frequently large films of white substance were formed on the tonsils," and describes a film or membranous substance lining the windpipe. Dr. Cheyne, in his treatise on the Pathology of the Membrane of the Larynx and Bronchi, published in 1809, says: "I have seen children so affected that I at first imagined they were suffering from the second stage of croup, but upon examination I discovered 'sloughs on the tonsils and uvula.'" The cough, voice, and breathing were those of the second stage of croup. He doubts whether these were cases of "true croup," but it can scarcely be doubted now that they were cases of diphtheria. Dr. Wade, in a communication to the *British Medical Journal* in 1875, gives the following quotations from an old author, showing that the existence of symptoms which we now recognize as diphtheritic paralysis was noted. They are extracted from a book entitled: An Historical Dissertation on a Particular Species of Gangrenous Sore Throat, which reigned Last Year among the Young Children at Paris. Translated from the French of Dr. Chomel (printed at Paris in 1749) by N. Torriano, M.D., London, 1753. "Miss Blossae, aged six and a half years. . . . The patient did not seem to be quite out of danger till the forty-fifth day of the disease, having always a pain in expressing herself, speaking through her nose by reason of the fallen palate. She was given, in order to lessen the disagreeable speaking through her nose, a little camphorated brandy, with equal parts of warm water to draw up her nose, for two months together, and she used the remedy with pleasure. Miss Bonae was taken ill of the disease and cured. . . . I have since learned that this patient after the fortieth day of the disease spoke much through her nose, became squint-eyed and deformed, but that as she grew stronger she also regained day by day her natural

state." The writer says "the patients are a long time weak and languid." To Bretonneau, however, belongs the honor of having clearly elucidated the distinctive characteristics of the affection. In 1821, 1825 and 1826, the disease having broken out and prevailed as an epidemic at Tours in France, Bretonneau, with his pupils Velpeau and Trousseau, studied it carefully and found a remarkable uniformity in its symptoms and post-mortem appearances, and from the constant presence of a false membrane called it diphtheria.

The characteristic feature of diphtheria, as already stated, is the presence of a false membrane situated upon the fauces. At the outset of the disease there is redness of the fauces, with more or less swelling of one or both tonsils. The exudation usually first appears upon one of the tonsils; but the diphtheritic formation may begin in the nares, pharynx, or larynx, on the palatine arches, uvula, and the posterior surface of the soft palate. At first the false membrane is thin, but may become more or less thick and opaque; it is white or ash-colored, but may become dark, and when unusually thick it resembles parchment or chamois leather. Sometimes the exudation is thin and soft, and sometimes it is tough and elastic, and an eighth of an inch in thickness. Different cases differ in the extent of the exudation; one or both tonsils may alone be affected, and from this primary seat the false membrane may extend over the pharynx, soft palate, hard palate, palatine arches, and uvula; into the nares, larynx, trachea, bronchi, œsophagus, and even into the stomach. It may be uniformly diffused in these situations, but it is oftener in irregular patches. The diphtheritic growth generally penetrates beneath the epithelium of the mucous membrane into the submucous tissue, coming into close contact with the blood-vessels, and, if detached, a raw, bleeding surface is exposed, which is soon covered with a new layer of false membrane.

Sooner or later the false membrane is thrown off, but the exfoliation is not infrequently followed by a second, third, and even fourth formation of false membrane. Decomposition of the exudation often takes place rapidly, and hence arises the fetid effluvia exhaled from the mouth of the patient. The glands to which the lymphatics of the pharynx lead are found to be larger than natural, and such an enlargement of the glands is in just proportion to the extent and severity of the local disease within the throat. If the local disease is limited to one side, the glandular enlargement occurs on the same side, and in severe cases not only do the glands behind the angles of the jaw enlarge, but the connective tissue in which they are situated is often the seat of serous effusion, and even of the exudation of lymph, so that great swelling occurs, which sometimes results in suppuration. According to Dr. Niemeyer, the diphtheritic and croupous false membrane is composed of fibro-albuminous material, which rapidly coagulates when thrown out upon the free surface of a mucous membrane. By some authorities it is considered to be a peculiar exudation, which, forming a favorable nidus for fungi, is often the seat of cryptogamic growth. Others maintain that the fibrinous material is poured out only in consequence of the irritation set up by a parasitic formation ramifying between the epithelial layers of the mucous membrane. Microscopically it is seen that pus, granular corpuscles, oleo-protein granules and epithelium constitute the bulk of the softer forms of diphtheritic exudation, while fibrin mixed with corpuscles constitute the bulk of the tougher varieties. The microscope often reveals the

presence of fungoid vegetation in the pellicle diphtheria, and some observers have asserted that a parasitic growth is always present in the false membrane of this disease.

The invasion of diphtheria is sometimes attended with symptoms so mild as scarcely to attract attention until the local disease has made considerable progress. No pain is felt in swallowing, no febrile excitement is present, and only a trifling soreness or roughness is experienced in the throat. Other cases begin with feelings of depression and general malaise, attended with chills, fever, headache, sore throat, stiffness of the neck, and more or less pain in deglutition, and sometimes an attack is ushered in by convulsions.

The *primary nasal form* commences like a cold in the head, or the snuffles, the patient is unable to respire through the nostrils; from which there takes place a serous, yellowish, flocculent or bloody discharge, often very fetid, and which produces more or less excoriation of the external nasal openings and of the upper lip. This form is apt to be overlooked until symptoms of exhaustion supervene, or of the extension of the disease to the fauces or larynx.

In the *primary laryngeal form* the disease begins with painful deglutition, attended with redness and swelling of the mucous membrane of the fauces and noisy respiration. The exudation may be often seen on the arches of the palate, being more abundant at the base of the arch, looking as if it had spread from the larynx. Croupal symptoms rapidly supervene, and death threatens from apnoea.

MEMBRANOUS CROUP IS DIPHTHERIA.

I believe membranous croup and diphtheria to be identical. On reviewing, lately, the prevailing opinions of the leading members of our profession, it appears they are daily more and more adopting the dogma of Bretonneau and Trousseau, that all membranous croup is dependent on the specific contagium of diphtheria. It is, then, unquestionable that in the vast majority, if not in all cases, a membranous exudation in the air-passages is the specific product of diphtheria. The absence of exudation on the fauces does not prove the croup to be non-diphtheritic; for the diphtheritic formation may begin in the larynx, or, what is more common, the membranous exudation, which first occurred on the fauces, may become detached therefrom while the disease is extending downward into the air-passages, so that on inspecting the throat no exudation is observed. It is admitted by the best authorities that the morbid anatomy of membranous croup is identical with that of diphtheria.

The sequelæ of diphtheria form an important part of its history. Anæmia and general debility are apt to persist for a considerable time. Feebleness of the action of the heart sometimes exists to such a degree as to lead to sudden death by syncope, which is due in some cases to a paralyzed condition of the heart, and, in others, to the deposition of fibrin in the heart or great vessels. Paralysis is a characteristic sequel, the muscles of the soft palate and pharynx are often affected; the paralysis here precedes its occurrence elsewhere, and is denoted by the nasal sound of the voice, difficulty of swallowing, and the regurgitation of liquids through the nostrils. Paralysis of the limbs is gradually developed, and is preceded by tingling, numbness, and a sensation of coldness; but sometimes the sensibility of particular parts of the affected limbs is morbidly increased, so that the lightest touch causes great distress. Paralysis of the external recti muscles sometimes occurs, resulting in

converging squint. The senses of sight, taste, smell and hearing are sometimes affected. Concerning the pathology of diphtheritic paralysis there are several theories. Dr. Morrelli, in his essay on Diphtheritic Paralysis, as observed in Florence from 1861 to 1864, gives some dissections in which lesions were found in the spinal cord and nerves. He remarks that the changes found after death are inadequate to explain the various forms of diphtheritic paralysis, and leave it an open question whether the pathogenesis of this affection be not entirely due to the morbid causes of diphtheria, and whether the paralysis does not proceed from the periphery to the nervous centres. Other Italian and German physicians have described autopsies in which they have found a disseminated myelitis in the medulla and spinal cord. Two recent observers, M. Charcot and M. Vulpian, are of the opinion that diphtheritic paralysis is due to the periphery rather than to changes in the nervous centres; that it is, in fact, an extending neuritis or inflammatory process propagated from the muscular surfaces and nerve extremities, which produce abolition of their functions. They have shown that the normal condition of the palatine nerve is altered; that the nerve tubules are devoid of myeline, and granulations are seen to exist in the neurilemma.

Diphtheria is classed among the zymotic diseases. It is a contagious disease, and is apt to become epidemic. Examples of persons becoming affected, after having been brought in close contact with the disease, are numerous. But it sometimes occurs sporadically, and shows no disposition to spread from the sick to the healthy. In what manner the specific contagium or poison of diphtheria is generated has not yet been solved; filth, sewer and cesspool gases, defective drainage, dampness arising from soil moisture, or rather a damp atmosphere charged with the fungi of decomposition, are said to give rise to the disease. A German author, Dr. Letzerich, says "that it is undoubtedly deduced that epidemic diphtheria is caused by a fungus whose spores can carry the disease to other individuals; that diphtheritic inflammation depends upon the local effects of cryptogamic productions, and that clinical experience shows that the false membrane may be prevented if the spores and sporules are destroyed by topical applications." Once originated from any cause or combination of causes, it may be communicated by the sick to the healthy.

I regard diphtheria in its incipient stage as a local disease, and the early constitutional symptoms that sometimes occur, as due to the irritation caused by the growth on the mucous membrane, and the ramification beneath its epithelium, of the diphtheritic formation, and I regard the subsequent infection of the system and constitutional disease as resulting from the absorption from the throat or other seat of the false membrane, of the poison, and of putrescent matters arising from the interstitial death of the mucous tissue invaded, and from the decomposition of the false membrane. *We cannot too forcibly impress upon the public that the severity and mortality of the disease can be controlled if it is brought early under treatment.* If this fact was generally known and heeded, we could regard the disease as one of the most trivial of throat affections, with here and there a grave exception. Diphtheria is often masked for a time by symptoms of other diseases, so that when diphtheria is prevalent it is expedient to look into the throat of the patient in all cases of illness, as occasionally, when there is not even ground for suspicion, the characteristic spot or film of false membrane can be observed. What is the first stage of diphtheria? That in which the germs

of the disease have lodged on a surface which provides a favorable soil for their development. The locality which is chosen by the contagium particles of diphtheria is usually the throat, generally one of the tonsils, where they begin to multiply and spread over the adjoining mucous surface, like mould on a raspberry jam. The disease has not yet impregnated the constitution with its baneful influence; perchance the pulse is not quickened; the temperature is not raised, and the tongue is not furred. Now is the time when a speedy cure can be effected by local treatment, when a single topical application will often effectually destroy the parasitic growth, and the patient is rescued. Contrast this with the disease not seen until it has been some three or four days established, the poisonous matter from the film has been absorbed by the lymphatics, as indicated by the hardening and swelling of the neighboring glands, the false membrane has spread more or less over the fauces and into the nasal cavity, perhaps entering the larynx, when recovery can scarcely be looked for; the pulse rapid, the temperature exalted, nerve prostration extreme, the blood badly or hopelessly poisoned, and protracted illness or death imminent.

In the treatment of the first stage of diphtheria I formerly applied to the false membrane lunar caustic or a strong solution of the nitrate of silver; but lately I have used, as a local application, the following preparation: R.—Acidi carbolici, 15 drops; tinct. ferri chloridi, 4 drachms; aquæ, 4 drachms. M. This solution, by its astringent and antiseptic properties, tans or hardens the fibres and coagulates the fluids of the false membrane, thereby arresting its growth and preventing the occurrence of putrefactive changes therein. It should be applied to the false membrane *once*, rarely twice, daily, with a small probang which has been moistened with water and pressed out just before being dipped in the solution. Some physicians experience considerable difficulty in making topical applications to the throat of children, but if they adopt the following procedure they will easily succeed: The mother, sitting, should take the child in her *right arm* and hold its hands; another person standing behind the child should hold its head, while the doctor should depress the tongue with a spatula or spoon-handle, held in his left hand, and with his right apply the probang, dipped in the solution, to the throat; after one application has been made the probang should be rinsed in water, cleaned of the attached mucus, dipped again in the solution, and re-applied; this repetition is necessary, so that the solution may come in direct contact with, and thoroughly permeate the false membrane. This operation should not be performed oftener than *once* or twice in the twenty-four hours, as strong local applications are apt to do harm when too frequently repeated. One application thoroughly made as directed, in the incipient stage of diphtheria, will oftentimes arrest the disease, causing the general symptoms to subside in a short time, and the false membrane to shrivel and disappear within twenty-four hours. While the local applications are being made the following prescription may be administered: R.—Potassii chloratis, 1½ drachms; aquæ, 4 ounces; acidi muriatici, 10 drops. M. Take a teaspoonful every hour during the day, and continue its use a few days after the false membrane has disappeared from the throat.

In the *next stage*, when the constitution has become impregnated with the diphtheritic poison, the false membrane will reappear if it is destroyed; so that local applications, though beneficial, cannot be relied upon to arrest the disease, which should now be chiefly

treated by the administration of tonics, antiseptics, stimulants, and a nourishing diet. An excellent prescription containing tonic and antiseptic qualities, and the one which I generally give, is the following: *R.*—Potassii chloratis, $1\frac{1}{2}$ drachm; aquæ, 4 ounces; tinct. ferri chloridi, $\frac{1}{2}$ to 1 drachm; quiniæ sulphatis, 2 to 5 grains. *M.* Take a teaspoonful every hour during the day, and continue its use one or two weeks after the local disease has disappeared. Water should not be taken for at least five minutes after each dose of the medicine, so that it may have time for local effect on the fauces. When there is much fetor exhaled from the fauces, the mouth may be occasionally rinsed, and the throat gargled or sprayed, with the liquor sodæ chlorinatæ, 5 to 20 drops to the ounce of water, or with aqua chlorinii, 5 to 15 drops to the ounce of water. Stimulants are required in this stage, the best being sherry wine diluted with an equal quantity of water, and the amount given should be in proportion to gravity of the disease and to the age of the patient. A liquid diet only should be allowed, consisting of milk, beef essence, beef tea, porridge, gruel, soup, etc., until convalescence begins, when a more substantial diet may be partaken of. In the nasal form, when the discharges are offensive, the nostrils should be carefully syringed out with potassii permanganas, 1 to 2 grains to the ounce of water; but if there be hemorrhage, the tinct. ferri chloridi, 5 to 10 drops to the ounce of water, may be used.

In the primary laryngeal form, or when the disease is entering, or has extended into the larynx, the following, vaporized by the steam atomizer, may be almost constantly inhaled for the purpose of effecting the solution of the false membrane: *R.*—Aque calcis, 4 ounces; acidi carbolic, 10 drops. *M.* Tracheotomy should be performed when other means have failed, and, according to Prof. George Buchanan of Glasgow, the operation yields as successful results in diphtheria as it does in membranous croup. In 1875 he published the whole number of his operations, which was 46: for croup, 16—cured, 6; died, 10; for diphtheria, 30—cured, 11; died, 19. The average result is precisely the same, viz.: one out of every two and two-thirds is saved.

In the paralysis resulting from diphtheria, no special treatment is required in most cases, but in the exceptional instances in which the paralysis persists a cure may be generally effected by the use of electricity, the subcutaneous injection, or the internal administration of strychnine, and an eligible formula is as follows: *R.*—Strychniæ sulphatis, 1 grain; aquæ, 1 ounce; tinct. ferri chloridi, $\frac{1}{2}$ drachm; syrapi zingiberis, 3 ounces. *M.* Dose for adults, one teaspoonful; for children one to three years old, five to ten drops, thrice daily.

OPHTHALMIA NEONATORUM.

By WILLIAM OLIVER MOORE, M.D.,

ASSISTANT-SURGEON NEW YORK EYE AND EAR INFIRMARY, ETC.

This disease is one of the most terrible and destructive that can affect the eyes of the new-born. Fully one-half of the inmates in our blind asylums had this disease when only a few days old, and have suffered a lifetime in consequence. Scarce a day passes but we see presented at the various eye hospitals the sad picture of a helpless infant, frequently only ten days old, sometimes younger, in whom this disease has made sad havoc, one or both eyes being totally destroyed.

The question naturally arises, has science no means at her command to combat this disease? Most assuredly.

The disastrous results so frequently seen are not from lack of means, but from the lack of applying sure and safe remedies to the unfortunate patient.

It is a disgrace to the medical profession that so many children annually become blind from this disease, owing to utter ignorance of the first principles of medicine.

The dunlest practitioner, if called to see a case in which a discharge of pus so profuse as that coming from ophthalmia neonatorum, would, if in any other part of the body, immediately institute means to allay and check it, and would not for a moment advise "breast-milk" as a lotion. Yet good general practitioners, when called to see this disease, sit quietly by, and with folded hands say, "It is quite common, and of no consequence," a matter of "only a few days;" meanwhile the eyes are being rapidly destroyed, and the innocent victim is to reap a lifetime of sorrow for the indifference of the family physician.

Of five hundred cases treated at the New York Eye and Ear Infirmary during the past ten years, only fifty were delivered by midwives; the others were under the charge of practitioners of medicine. Thus, in the majority of cases, the neglect can be traced to the physician in attendance.

The more astonishing is the fact, as this disease usually makes its appearance during the first ten days of life, when, as a rule, the accoucheur is daily visiting the mother.

Not until the mass of the profession realize the importance of energetic and thorough treatment, will we cease to see the awful results now so common.

We are required by the Board of Health to report scarlatina and the like, which can but produce, at the worst, death; while with this disease hundreds yearly are made to live a life of darkness from want of proper treatment—a burden not only to themselves, but also to the State.

We would almost urge the reporting of every case of ophthalmia neonatorum to the Sanitary Bureau, that it might be investigated and have proper treatment. This would be of service, as all physicians diagnose the disease, though they are so indifferent as to its treatment.

Some will probably think this visionary and wild; but those who visit our special institutions will see the truth of the matter. I would not be understood that the specialist is the only one fitted to treat such cases.

The most frequent cause is improper cleansing of the child's eyes and face immediately after delivery, or from using, in bathing the child, a soiled towel or sponge containing poisonous matter from the mother.

Great care should be exercised in having a trusty and tidy nurse. Exposure to strong sunlight, which is indulged in by too many, is another cause; as is also cold, causing a catarrhal inflammation in delicate infants, rapidly degenerating into a purulent form.

The disease generally makes its appearance during the first three days of life, when either one or both begin to show slight redness of the edges of the lids, and some injection of the ocular conjunctiva, together with undue moisture of the parts. The tissues of the lid being very lax in the infant, œdema of the lid soon manifests itself, especially in the upper, which has a red, and in many cases a purple hue. This swelling of the lids entirely shuts the eye from view. The discharge, which at first was only small in amount, and mucous, has by this time become very profuse and purulent. Frequently the purulent secretion

runs down over the cheeks, especially from the inner canthi. The edges of the lids become agglutinated, and, when forcibly separated, the pent-up purulent matter gushes out.

This confluant material is a potent element in causing the destruction of the cornea, which so frequently happens where thorough washing is not practised.

The child, in crying, will often evert the upper lid, owing to the great swelling and to the contraction of the orbicular muscle. This point is a help in the treatment, as it greatly assists when making the application to the lid. The palpebral conjunctiva will be found intensely injected over its entire surface, and especially inflamed and swollen at the retro-tarsal fold.

On examining the cornea we find diffuse or circumscribed haziness, or, in the more severe cases, deep sloughs. This necrosis usually causes destruction of the entire thickness of the cornea, allowing thereby prolapse of the iris, in some even escape of the crystalline lens.

A case is on record where the mother brought in a wine-glass both lenses of her child to the physician.

Sometimes one-half, and at others the whole cornea is destroyed, according to the severity of the disease. The discharge and swelling will last for weeks when no active treatment is adopted, when at length the eyes are either sightless or very much impaired.

Such is the history of a case without treatment. The prognosis is favorable if the patient is seen within forty-eight hours of the attack, and, as a rule, no corneal complication will occur unless the child is extremely delicate and poorly nourished.

Prevention.—If the physician would attend more particularly to the first bath of the new-born, and not leave the entire charge to a nurse—perhaps an ignorant one—much trouble and suffering might be averted. All the bathing utensils should be perfectly free from any contamination of the mother. These seeming trifles well attended to will prevent many a case. The treatment may be divided into two parts; one to be carried out by the physician, the other by the nurse or attendant.

First.—The patient should be seen daily for the first two weeks. Remove all secretion from the edges of the lids by a moist cloth; separate the lids gently and examine carefully the cornea. If, in everting the lids, there is little or no bleeding from the conjunctiva, apply, after removing all adherent secretions by means of a camel's-hair pencil, a solution of argenti nitratis (gr. x. ad xx.—aq. ℥j.) carefully to the upper and lower lid. Some neutralize the excess of silver by applying immediately a solution of chloride of sodium. This we think unnecessary, as the secretions of the eye usually neutralize any excess of silver. The lids should then be placed in their natural position. The cornea should be inspected at each visit, and, if hazy, a weak solution of atropia sulph. (gr. ss.—aq. ℥j.), instilled. We prefer the ten-grain silver solution with the occasional use of the "mitigated stick" 1:2 (composed of nitrate of silver and potassa).

This treatment is kept up daily until the swelling of lids disappears, cornea clears up, and secretion ceases. The secretion being highly contagious, both the physician and nurse should be very careful and wash their hands after each application.

Second.—The treatment by the nurse or mother. This is really the most important, as the cardinal point is extreme cleanliness of the eyes. A few pieces of old linen, about two inches square and of only one thickness, should be placed upon a small block of ice, and, when cold, placed upon the closed lids of the

patient. When these become warm they should be replaced by cold ones. This should be kept up as long as the child will tolerate it. One-half hour six times a day, until the discharge and swelling sensibly decrease, will be none too long at first.

The eyelids should be carefully separated every hour and cleansed of all secretions adhering to their edges, and the secretion in the conjunctival cul-de-sac washed out by means of a solution of alum (℥j.—aq. Oj.), by means of the ordinary medicine-dropper or pipette. In this way only can thorough cleansing be obtained. Chlorine water diluted may be also used with good result. We object to the use of solutions of lead, as frequently deposits of it have been found upon the cornea. Vaseline applied to the edges of the lids acts a good purpose, and should be used often during the day. This method, faithfully carried out by the mother or nurse, will add largely to the safety of the eyes.

The above treatment is, we believe, the one most commonly practised by ophthalmologists. Certain we are that a patient seen within forty-eight hours will have no impairment of vision if subjected to the above.

The prolapse of iris and other complications occurring in the cases not under treatment early, need special care, which we will not at present detail, as we hope to diminish largely such results by arousing the general practitioner to the importance of early and prompt treatment.

Care should be given to the general health of mother and child, as often the virulence of the disease is due to bad nutrition.

We hope these few remarks will be accepted in the spirit in which they are given, and that they will arouse attention to this destructive disease.

133 EAST THIRTY-EIGHTH STREET, NEW YORK.

CLASS-ROOM LESSONS ON CHANCROID.

GIVEN AT THE COLLEGE OF PHYSICIANS AND SURGEONS
IN THE CITY OF NEW YORK.

BY FESSENDEN N. OTIS, M.D.,

CLINICAL PROFESSOR OF GENITO-URINARY DISEASES.

(FOR THE MEDICAL RECORD.)

II.

THE TRUE NATURE OF CHANCROID—DIAGNOSIS OF APPARENT CHANCROID.

GENTLEMEN:—I will next direct your attention to the question of the *true nature of chancroid*, for it is essential that this should be appreciated before proceeding further in our study of the affection.

If it is a specific disease, that is to say, only capable of being set up through contact with the secretion of a previously existing chancroid, then acquirement of chancroid is proof indisputable of criminal venereal contact, either by the subject of it, or of the one from whom it was mediately or immediately contracted. It will at once be seen that this is a point which may become of great importance in its medico-legal relations. It will then be worth our while to pass in review some of the known facts bearing upon this matter.

First let us determine exactly what is understood by the term *chancroid*. We may accept the usual definition, namely, that sores promptly following venereal contact (from 24 hours to 8 or 10 days), possessing the destructive and contagious property are called

chancroid, and are claimed by certain authorities to be due in every instance to a specific virus.

Fournier says this in the most emphatic way, thus: "If all the patients in the world with chancroid would avoid contact with others until their malady got well, the disease would cease from off the earth." This is quoted in a recent work on syphilis, etc., by Drs. Van Buren and Keyes, and emphasized by a positive statement that chancroid arises only from chancroid. (Page 477.)

It is known and accepted that chancroids vary in activity, from those which are highly contagious and rapidly destructive, to those which are feebly destructive and are inoculated with difficulty. This is a well-known clinical fact, and has been repeatedly proven in the experiments with artificial inoculations by Boeck and others.* "A certain pus is employed '(chancroidal)' and re-inoculated until it will no longer produce a pustule; then fresher pus from some younger chancroid, until it also fails." †

If this decadence takes place in the artificial inoculation, it is not reasonable to suppose that the same result would be reached by repeated inoculations through venereal contact. Hence the chancroid by the continued re-inoculations of venereal contact would grow less and less virulent as communicated from person to person, until it finally died out.

Unless therefore new foci of contagion were created, or new virulence added, chancroid would long ago have "ceased from off the earth." We must then take one of these two positions in regard to it; either some added virulence must be accepted as arising from circumstances connected with the venereal contact (since it has been conclusively shown that by simple re-inoculation chancroid speedily loses its contagious and destructive properties), or that from circumstances connected with venereal contact new chancroids are originated. It is not necessary that we should be able to explain the exact combinations which increase the virulence of a declining chancroid, or which give rise to it *de novo*, in order to prove that certain possible conditions really do intensify and even originate chancroidal action or virus. If there is a difference between the behavior of the chancroidal virus when inoculated by means of a lancet, and when inoculated through venereal contact, that difference can only be referred to the circumstances attendant upon the venereal act. How, then, do the circumstances differ in an artificial and in a venereal inoculation? In the first, we have the virus inserted free from local or general circulatory excitement. In the second, both are distinctly present. Under circumstances of equal cleanliness and equally free from undue tendency to purulence, the result might not be markedly different. But to the latter mode of inoculation, viz., that by venereal contact, we may have, in addition, various potent influences, such as increased irritation from irritant leucorrhœal menstrual and preputial secretions, filth, excessive venereal indulgence. Each one of these added conditions is well known to be capable of initiating local inflammation and of increasing inflammatory processes already instituted. It can even be shown that a combination of these conditions may originate a lesion which distinctly exhibits loss of tissue, and the secretion of which is capable of setting up a similar lesion on an opposing surface, therefore possessing the contagious property. If this can be proven, it seems to be clear that the difference between a lesion thus produced and the typical so called *specific*

chancroid is simply one of degree, and it may be logically claimed that circumstances which have been shown capable of setting up such a lesion, and which are shown to add to the virulence of a declining typical chancroid, may under favoring conditions produce an actively destructive, promptly contagious lesion—that is to say, a typical chancroid.

Now, it is a well-recognized clinical fact that certain conditions predispose to purulence. A lowered state of health, free from any disease, was shown in Dr. Wigglesworth's case, not alone to favor simple suppuration, but to be capable of producing pus of a distinctly contagious character.*

Persons affected with syphilitic disease,* scrofula, scorbutus, chronic splenitis, etc., are also predisposed to purulence; this can also be said of the subjects of every species of dyscrasia. Local conditions may also increase the suppurative tendency. Redundant preputial tissues—producing undue heat, moisture, and friction, favor purulence; also, dependent position. Prof. Boeck's experiments in inoculations of chancroid showed that the higher upon the body inoculations were made, the less tendency to excessive suppuration and also to phagedæna.

Again, it is a well-established fact that changes occasionally take place in purulent secretions, through which new qualities and powers are developed. Benign or "laudable" pus may thus acquire a highly irritant property, as shown in the following case:

CASE I.—A gentleman was presented to me some time since complaining of an inflamed condition of the glans penis and prepuce, which inflammation, as he said, followed every connection with his wife. On examination, the preputial tissues were found to be redundant, and the mucons membrane of the glans, as well as of its preputial reflection, was intensely congested and bathed in a muco-purulent secretion: this condition appearing at once after connection, increased, the parts becoming moist and painful, and continuing more or less so for several days. The wife was said to be afflicted with a profuse purulent vaginal discharge. It was also stated by the patient that connection with his mistress was not followed by any such trouble.

Again in certain cases, instead of a diffused inflammation we may find more strictly localized inflammatory lesions from a similar cause, as will be shown in the following case:

CASE II.—Mr. II.—consulted me about five years since on account of a pustular eruption on the preputial mucons membrane, near its attachment at the fossæ glandis. His first trouble had appeared about six months previously as a single pustule in the fossæ on the right side. This was shown to a surgeon, who, notwithstanding the patient's assurance that he had no connection except with his wife, promptly pronounced it a chancroid and cauterized it with nitric acid. Within a day or two several small vesicles appeared in the vicinity, when the surgeon came to the conclusion that the primary lesion was of the same character, and that all were herpetic. The vesicles also became pustular and healed under a simple astringent dressing. There was a history of several subsequent similar attacks. In view of these facts the half-dozen lesions presenting on his first visit to me (previously alluded to), although distinctly ulcerative, with inflamed border, and varying in size from a small split pea to a grape-seed, were considered of herpetic origin. The correctness of this view was confirmed by their rapid healing under simple astrin-

gent applications. A mild tannic-acid lotion was prescribed as a prophylactic, which, however, did not prevent recurrence of the trouble within a week. This yielded like the previous, and a lead lotion was used, with the apparent effect of preventing further trouble for nearly a month, when the patient went off on a fishing excursion. On his return, some ten days after, he presented not only pustules on the site of the previous ones, but several on the glans penis *exactly corresponding to the locality of pustules on the preputial mucous membrane when drawn forward on the glans*. In addition, there was a somewhat painful enlargement of the inguinal glands of the right side, attributed by the patient to taking cold after resting the butt of his brass rod for several hours in the groin of that side. The pustules healed somewhat tardily under repeated applications of nitrate of silver, but the glands went on to supuration and the formation of deep sinuses. All healed, however, in a couple of months, when, three days after connection with his wife, another crop of pustules was discovered.

It was then suspected that the difficulty was the result of the connection; and upon a careful retrospect, the patient came to the conclusion that several, if not all of his previous attacks, had followed similar connection after about the same interval.

On inquiry, the wife was found to have been, for the previous six months, under treatment for an obstinate uterine catarrh by a distinguished gynecologist, who fully confirmed my opinion that contact with the acrid leucorrhœal discharge had occasioned the husband's trouble. Her final recovery and his subsequent immunity from the so-called herpetic trouble fully supported this conclusion. Both the gentleman and his wife were wholly free from suspicion of any illicit contact.

Another instance of ulcerative and contagious lesions from non-specific causes will be recognized in

CASE III—Mr. S —, aged twenty-seven, had been married about two years, when, after the birth of a second child, his wife suffered from a leucorrhœa which continued more or less troublesome for several months. In seeking my professional aid for himself, he stated that during this time he was subject to occasional attacks of herpes preputialis, and that whenever any abrasions occurred during connection, they were sure to be followed by points of ulceration, which only healed after several days' treatment by bathing and simple cerate. On examination, several sharply cut ulcers, from one to two lines in diameter, were seen on the preputial reflection and in the fossæ glandis. There were also two on the glans penis, more recent and smaller, which matched exactly upon similar lesions on the preputial reflection when the prepuce was drawn forward. The current attack was said not to differ essentially from those to which he was accustomed, except in that it was associated with enlargement of glands in both inguinal regions. One point especially, in the right groin, was inflamed, sensitive to touch, and fluctuating. This was opened, and discharged a small quantity of laudable pus. The ulcerations healed under the influence of cleanliness and simple applications; the patient necessarily keeping at his business as book-keeper in a large wholesale establishment; but the glandular abscess—the only one occurring—lasted for a full month before healing was complete. The patient's general health was fair. No scrofulous or syphilitic antecedents. The only apparent causes predisposing to ulcerative trouble was a very moist and redundant prepuce, which was subsequently removed. Since the circum-

cision, now four years, there has been no reported recurrence of the herpetic trouble.

Again, it would seem that ulcerations may occur under certain circumstances, as a result of contact with vitiated normal secretions, as shown in the following:

CASE IV.—A gentleman who had been under my professional care for several years previous, and had no occasion to misrepresent his case, sent for me. He stated that he had a gonorrhœa acquired from an illicit connection with the wife of an intimate friend thirteen days previous. On the completion of the act, the lady discovered that she was menstruating, and so remarked, with many expressions of regret. Some four days after, a little soreness was felt in the urethra, near the orifice, and in a day or two more a whitish discharge appeared. He consulted a medical friend at his club, who, after hearing of the exposure, pronounced the trouble gonorrhœal, and treated him with capsules and an injection. After ten days of this, getting neither better nor worse of the discharge, a tenderness and swelling of the right inguinal gland occurred. Through his wife's solicitation, he sent for me. On examination I found a very scanty purulent discharge from the meatus urinarius, on opening which a sharply cut ulceration was seen just within the orifice, and about the size of a grain of rice; there was no urethral tenderness beyond this point. The gonorrhœal remedies were discontinued, and the lesion thoroughly cauterized with argentic nit., solid. An inflamed bubo of the right inguinal region, size of a walnut, was also present; no fluctuations. This was painted with iodine. Suppuration occurred after several days, and the abscess was freely opened, discharging apparently healthy pus. Auto-inoculation of this pus failed to produce any result. The urethral ulcer resisted repeated cauterizations for about a fortnight, and then healed. At about this time the wife began to suffer from painful urination, and an examination revealed a superficial ulcer of mucous membrane, the size of a three-cent piece, just below and infringing upon the meatus urinarius, secreting pus freely. The husband acknowledged to an attempt at connection on an evening following the illicit intercourse, but stated that, with this exception, it was the only one, except with the friend's wife, that he had for a full month. In addition, the lady had a swollen and inflamed inguinal gland in the right groin. The lesion at the meatus urinarius was touched with pure carbolic acid, previously to which, however, the purulent secretion from it was inoculated on the thigh of the husband. The result of this inoculation was negative. Notwithstanding repeated applications of the carbolic acid, the ulceration in the wife progressed in depth and extent during the following ten days, until it invaded the urethral canal a full quarter of an inch; then an application of pure nitric acid was made. During this time several more unsuccessful inoculations were made upon the husband. Much urinary distress occurred, and notwithstanding the application of the nitric acid, the ulceration progressed along the urethra, which in the meantime was treated by suppositories of iodoform and cocoa butter. The lady was in delicate health, but without any constitutional dyscrasia. Tonics were administered, but the suffering increased and the ulceration was advancing into the deeper part of the urethra. During all this time the lady with whom the husband had the illicit intercourse had been calling almost daily on visits of courtesy and condolence, and both were free from any trouble. A distinguished surgeon, an

authority on genito-urinary diseases, was then called in consultation. To my great surprise he stated it as his opinion that the ulceration in the wife's case was non-specific, and only a coincidence; not at all the result of contamination from the husband, but from other accidental causes, and advised a continuation of application of the iodoform; if this failed to benefit, a change of air, a sea voyage. No improvement taking place in a week, the parties made a voyage to Havana, and, without other treatment, recovery practically took place within a fortnight.

Progress of Medical Science.

A NEW TEST FOR THE PRESENCE OF BILIARY COLORING MATTER IN THE URINE.—Nitric and hydrochloric acids, according to M. Masset, are not as delicate tests for the coloring matter of the bile as nitrate of potassium. The urine to be examined should be acidulated by two or three drops of concentrated sulphuric acid, and a small crystal of the nitrate dropped into it. The reaction is immediately established, a beautiful grass-green color being produced, if the quantity of the biliary coloring matter is large. On shaking the liquid the color becomes uniform, and of a deep tint; boiling does not change it, and it may be preserved for several days without alteration. The addition of water simply diminishes the intensity. If the biliary matters are present in but small quantity, the liquid takes in a very short time a pale green color, which also is persistent; it can easily be perceived by placing the tube between the eye and daylight, or in front of a white background. In these circumstances normal urine should present a light rose color. At the beginning of certain maladies, where the ordinary tests are useless, this reagent, it is thought, will be of service on account of the facility of its application and the distinctness, delicacy, and constancy of the reaction; further, it is not subject to the errors of observation, or the uncertain or erroneous interpretations attendant on the usual methods of examination.—*Journal de Médecine*, May, 1879.

ON THE SO-CALLED MYOSITIS OSSIFICANS PROGRESSIVA.—After giving an exhaustive anatomical description of two cases that were examined post-mortem in Heidelberg, Dr. Mays states it as his opinion that we have to deal in this affection not with a true myopathy, but with a process which starts in the connective substances—in the bones, tendons, and fasciæ, as well as in the connective tissue lying around and within the muscles. In the bony system the affection manifests itself by hyperostosis and exostosis, and by the development of synostoses (in the vertebral arches). Of the ossifications in the soft parts—which are demonstrated by the microscope to consist of actual bony tissue—many are directly connected with the skeleton, and this may then safely be assumed as the original point of departure of the process; while others are entirely isolated from the bony framework of the body, and evidently originated in the fasciæ or the loose connective tissue. The contiguous muscles merely lie on these osseous new-growths, from which they can be easily separated. The direction in which the new-growth extends does not at all coincide with that of the muscle fibres. Many connective-tissue structures undergo hyperplasia; the fasciæ are generally very strongly de-

veloped, and in some spots new tendinous bands and aponeuroses form. The pathological changes in the muscles themselves consist partly of simple atrophy and partly of fibrous and fatty degeneration. They may be regarded as secondary, and due to the altered conditions of nutrition and compression.—*Centralblatt für Chirurgie*, June 21, 1879.

MYX. EDEMA.—Under this name, M. Gull describes a disease characterized by a cretinoid state, occurring among adult women. It consists of a general enlargement of the whole body, especially marked in the face, which enlarges transversely, and becomes round. The skin becomes soft and delicate, and acquires a sort of transparency analogous to that of porcelain; the cheeks are rose-colored. The subcutaneous cellular tissue about the orbit becomes loosened; that of the back of the neck and of the throat, thick and folded. The distance between the eyes seems large, and the root of the nose depressed. The lips, large and thickened, are of a purplish red color; the alæ of the nose are hypertrophied. The face is modified in its shape, and assumes a bloated appearance, at the same time preserving a soft and rather agreeable look. The tongue becomes large and thick, the voice guttural, and pronunciation is impeded by the deformed tongue. The same changes appear in the hands, and they become infiltrated and massive. As the disease progresses the patient becomes listless, and capable of less and less exertion; the intelligence is dulled, and the habitual indifference is but rarely interrupted by periods of irritation. There is, properly speaking, no mental trouble. The trunk and inferior extremities become loaded with fat, giving the appearance of general œdema. Dr. Ord, who has observed similar cases, thinks that the disease is characterized by a gelatinous condition of the fibrillar elements of the connective tissue. Cases of this affection are extremely rare, and have been mostly reported from France under the general and vague name of polysarcia, or adipose polysarcia. M. Olive reports, among others, the case of a pensioner who became subject to a gradual solid swelling, which extended from the face to all the body, and which first made its appearance at the age of forty. The description of this case corresponds exactly with that given by Gull. Treatment does not appear to have been accompanied by much success.—*Journal de Médecine et de Chirurgie*, July, 1879.

TREATMENT OF DIPHTHERIA.—Prof. E. J. Bondorff, of Sweden, has had a very extended and successful experience in the treatment of diphtheria, and has used the following method for about twenty years:

In all cases, he has endeavored at the outset to determine the nature of the diphtheritic exudation and its seat. In more than a thousand cases of the disease which he has observed, he has found two different forms of exudation: (1) a superficial and evenly spread coating over one or both more or less swollen tonsils, and the arch or velum of the palate; (2) an exudation extending into the substance of the tonsils, on the surface of which are noticed more or less numerous white-gray spots, for the most part sharply demarcated, and of varying forms. The method of treatment consists in mechanically removing, by every means possible, the exudation and all mortified tissues which can be removed, and, when this has been done as thoroughly as possible, pencilling the surface with a strong solution of nitrate of silver. He dips a wet brush in powdered nitrate of silver, and then makes the application. This operation is to be repeated in severe cases twice a day, according as new masses of exuda-

tion are observed, and continued till no further exudation is perceived. The patient should be watched for several days, and should a relapse occur, the treatment must be repeated.—*Hygiea*, No. 4, 1879.

RAPID CURE FOR SINGULTUS.—Dr. Grelletz states that a mother whose child occasionally had singultus, either from the immoderate or too rapid repletion of the stomach, or from some other cause, was in the habit of checking the symptom instantly by the administration of a lump of sugar saturated with vinegar. The doctor tried this remedy in a number of cases, and always found it promptly successful.—*Rev. Med. & Giorn. Veneto di Scienze Med.*, May, 1879.

THE ORIENTAL PEST.—Prof. Hedenius read a paper before the Upsala Medical Society in which the history of the several outbreaks of pest, from the earliest times to the present, as well as the views of prominent writers on the subject, are critically examined. The pest is an extremely acute infective disease with a severe, adynamic febrile character, which is characterized by multiple localizations, especially in the external lymphatic glands (buboes), and occasionally also by the development of anthrax or carbuncle. In consequence of its febrile character, or the very prominent status typhosus, together with the localizations in the lymph system, the almost constant tumefaction of the spleen, and an occasionally occurring roseola, the pest would appear to be a specific variety of typhus, distinguishable from other typhus partly by its acute course—six to eight days—partly by the early appearance of the buboes. In consequence of the not unfrequent occurrence of carbuncles, which are sometimes primary, sometimes secondary in relation to the general disease, the pest presents several analogies with malignant pustule, but is distinguished from the latter by the simultaneous buboes, which occur most frequently without carbuncles. From pyæmia and cadaveric poisoning, which it undeniably resembles in many points, it is distinguished by its epidemic occurrence, and from pernicious chills by a more longitudinal enlargement of the spleen and by its contagiousness.

Besides this so-called Oriental pest, there is the Indian pest, a specific variety of pest in a nosographical and epidemiological point of view. The latter disease is also a bubo pest, it is true, and therefore very similar to the Oriental variety, but is distinguishable from it by a peculiar, probably septic lung inflammation, which occurs at the very commencement of the disease, is combined with pulmonary hemorrhage, constitutes the most dangerous symptom of this disease, and causes death on the second, or, at latest, on the third day—often before the appearance of the buboes.

The period of incubation, which is naturally of great importance in connection with the subject of quarantine, is very frequently only two to five days, and hardly ever extends beyond seven days after the infection.

Taking into consideration the fact that each epidemic, since the renewed appearance of the pest in the Orient in 1867, is more extended than the one immediately preceding, and that the disease has at last extended over the boundaries of Europe, it would undeniably appear as though we were threatened in the early future with a new pest period, and that strict protective measures were very necessary.—*Upsala Läkare för Förhand*, No. 2, 1879.

ANATOMICAL PROOF OF THE PERSISTENCY OF THE CERVIX IN PREGNANCY.—A long and excellent article on this subject was published by Dr. M. Säger, of Leipzig, in the *Archiv für Gynäkologie*. After an elab-

orate historical criticism of the question, in the course of which he controverts with great ability the views of Bandl and Küstner on this subject, the author gives an account of the condition of the cervix uteri in the case of a patient who had died suddenly in a convulsive seizure about the end of the ninth month of utero-gestation. Cæsarean section was performed immediately after death by Professor Credé, and the state of the uterus, and especially of the cervix, was carefully determined by Dr. Säger. It was found that the plicæ palmatæ of the mucous membrane of the cervix were perfectly intact, and that the membranes covered with the decidua ran closely down to the edge of the cervical mucous membrane. It was impossible to doubt where the cervix ended and where the lower uterine segment began. There was no intermediate space, as insisted upon by Bandl and Küstner, between what they call the inner os and ring of Müller. The anatomical evidence of the case, more especially when subjected to microscopical examination, in the most emphatic manner supports the view of the persistency of the cervix during the whole of pregnancy until near delivery, and contradicts flatly the view, that in any sense the cervix is used up in such a manner as to amplify the lower uterine segment. In Dr. Säger's case there was no elevated ring at the junction of the cervix and lower segment of the body, as in a case recently published by Müller, but the cervix and body of the uterus ran directly the one into the other in the same plane. Dr. Säger thinks that though anatomical evidence is the most reliable in deciding this question, careful clinical observations, taking care that the softened cervix is not shortened unnoticed during the exploration, is also of great value as corroborative evidence of the persistency of the cervix. The dimensions of the vaginal portion of the cervix in this case were as follows: Anterior wall, 1.5 centimetres = .6 inch; posterior wall, 2 centimetres = .8 inch; breadth of its base at the highest part of the vaginal end, 2.5 centimetres = 1.0 inch.—*Edinburgh Medical Journal*, August, 1879.

REMOVAL OF LOOSE CARTILAGES FROM THE KNEE-JOINT BY DIRECT INCISION.—Mr. Annandale reports two cases in which he opened into the knee-joint, with antiseptic precautions, for the purpose of removing loose cartilages. The first case was that of a coachman, aged sixty-eight. On the 4th of March a free incision was made into the joint, on its inner aspect, and three loose cartilages removed. The wound was stitched up, no drainage-tube being used. Union by first intention was obtained, and throughout the progress of the case there was no swelling or inflammation of the joint nor constitutional disturbance. The patient left the hospital on the 5th of April, cured. He has been heard of since, and the result is in every way satisfactory. The operation on the second case was performed on Oct. 5th, the joint being entered from its outer aspect, and the cartilage removed. As in the other case, the wound was closed, and no drainage-tube inserted. The wound healed rapidly by first intention, and after four dressings with the carbolic spray was found to be skinned over. No pain or swelling in the joint followed the operation, and the patient was discharged cured on Nov. 2d. He returned afterwards, and reported that he was able to walk long distances, with no inconvenience and no perceptible limp. Mr. Annandale thinks that the excellent results obtained in both instances proves the safety of cutting into healthy joints, provided the Listerian antiseptics be carefully employed.—*The Lancet*, Aug. 2d, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

W. L. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 20, 1879.

THE MEDICINAL USE OF ALCOHOL.

PROFESSIONAL interest in the alcohol question has not diminished. At the recent meeting of the British Medical Association an interesting discussion was held on the use of alcohol in the treatment of disease, and a number of noteworthy papers were read. The discussion was restricted to its use chiefly in fever. The first paper was read by Dr. James Little, of Dublin, on the value of alcohol in sustaining the powers of life in acute and chronic disease. The position which he assumes is, that alcohol as a drug has great power, both for good and for harm; that we are in danger of losing sight of its injurious influence while seeking its good effect; and that, on the whole, the consensus of medical opinion regarding alcohol is much too favorable. Wine and brandy are his favorite preparations, and, going back to Stokes and Corrigan, he accepts, as a guide for their administration in fever, the rule which, we believe, is especially emphasized in this country, namely, weak pulse, or, as an old and skilful practitioner used to say, a "swinging pulse," and feebleness of the impulse of the first sound of the heart. It does not necessarily follow, when these conditions are present, that the ears and extremities of the patient are cold, or that pulmonary stagnation is present—further indications for which Dr. Little impliedly looks. Indeed, those are the conditions which, we believe, a wise administration of alcohol, wine, brandy, or whiskey is capable of preventing, and towards which its use should be especially directed. In other words, we believe it is safer to aid nature when she first signals that her powers are flagging, than to wait until she cries out for assistance. This, however, does not imply that the remedy is to be used indiscriminately; but, on the other hand, it presupposes that the medical attendant deals with his case cautiously, and with his ear hears the first plaintive supplication for aid.

The diseases in which Dr. Little believes alcohol is specially serviceable are catarrhal typhus and pneumonia. Dr. H. Maenoughton Jones, physician to the Cork Fever Hospital, gives his experience in the treatment of 899 cases (independent of private cases) of typhus, typhoid, and simple continued fever, and reaches the conclusion that, while a large percentage of cases do not require alcohol, it is a most valuable therapeutic agent in both typhus and typhoid fever. He, however, has but little faith in the early employment of alcoholics in fever, even in those patients who have been addicted to their use, and has rarely seen any good effect from them when they are used to "prevent" an adynamic condition. In 1875 he published, in the *Dublin Monthly Journal of Medical Sciences*, a table of 310 cases of fever; of these, 220 had no stimulants, 58 had claret alone, and 33 had brandy. Of this number 110 were typhus fever patients, of whom 26 received stimulants. The mortality in the typhus cases was eight per cent.; in all the other cases, 3½ per cent. From 1875 to 1877, 30 per cent of the cases had stimulants at some period of the fever. From 1877 to 1879, 36.17 per cent. had stimulants; and in the typhus cases they were given in the greatest per cent. in the latter period of the disease, and the rate of mortality was about the same as noted above. The total percentage of cases of typhoid fever taking brandy was 20.56, with 36.36 as the rate of mortality; and the total percentage taking claret was 25.23, with a death-rate of 7.40. Of 117 cases of simple continued fever, 5.12 per cent. were given brandy and claret respectively, and no deaths occurred.

A feeble, irregularly acting heart, with weakened first sound, rapid compressible pulse, and absence of violent head symptoms, encourages him in their use and continuance. While he does not use alcohol to "prevent" the entrance of the wedge, he uses it to remove the wedge, or at least to arrest its riving effects, when its presence is indicated by the condition of the heart and the general condition of the patient to which allusion has just been made.

The discussion was continued by gentlemen who entertain extreme views on both sides of the question. Dr. Kerr, of London, believes the vital forces can be sustained by milk, unfermented wine, beef tea, and gruels while the fever runs its course, and rarely gives alcoholics. He fears the reactionary disturbance of alcohol, and claims that the circulatory system can be equally, promptly, and efficiently stimulated by means of injections of hot water, by the repeated injections of ether, by flying sinapisms and blisters, and by digitalis. We confess we are not quite able to understand what flying blisters and sinapisms can do towards sustaining the flagging forces of nature in an advanced case of typhus or typhoid fever, and prefer to submit ourselves to the care of an intelligent and discerning practitioner who aims to soothe and sustain rather than to irritate.

On the whole, however, there was a notable unanimity of opinion regarding the value of alcohol in the treatment of fever. As Dr. Andrew Clark, the President of the Section on Medicine, puts it, "it was apparently agreed that the patient in fever was like a ship in the storm; not much could be done for the storm, but a great deal could be done in steering the ship in the storm." The object is to support the life of the patient in passing through the perils of a fever; and when the patient's natural powers begin to fail, when his vital forces totter—danger becomes imminent and death threatens, there is perhaps no remedy more serviceable than alcohol. At the same time it should be given with a tentative hand, and, so long as certain evidences of disagreement do not arise, it may be continued, with the idea that we are aiding the patient in outliving the disease.

Besides this discussion, there is lying before us the Sixth Annual Report of the London Temperance Hospital—an institution for the treatment of all kinds of diseases without using alcohol in any way, even in the form of tinctures.

During the twelve months ending April 30, 1879, there were admitted to this hospital as in-patients 140 persons. This number is altogether too small to enable us to make a fair comparison, regarding many important features, between these patients and a like number treated at an ordinary hospital; but we can legitimately avail ourselves of the opportunity to examine the cases which are reported as illustrations of the good results obtained by what is termed "treatment non-alcoholic."

"CASE 633.—G. R—, aged 40; non-abstainer; cabman, and married; suffered from jaundice," which went through "all its phases" in seventeen days without the use of alcohol in its treatment. Recovery, even without medicine, can be expected with a great deal of confidence in all such cases.

"CASE 664. St. Vitus's dance.—J. C—, aged 8; life abstainer." The cause is put down as "fright." She remained in the hospital two months, and was discharged cured. It is an established fact that the tendency in this class of cases is towards recovery; and, besides, we have not yet seen it recorded that alcohol is a remedy ordinarily employed in its treatment.

"CASE 610.—W. C—, aged 24; abstainer;" was admitted to the hospital, July 15th, with "pneumonia of the left lung," and discharged cured on August 8th. A legitimate termination of the case, independent of any medicinal treatment whatever.

"CASE 682. Epithelioma of the lower lip.—P. S—, aged 40; abstainer; gardener." The growth was removed by "making a very free sweep with the knife." "The treatment was non-alcoholic," and the patient was discharged cured at the end of twenty-four days. Nothing but unforeseen causes and meddling interference could prevent such a result, if the operation was well performed.

Several other cases are reported, and with one or two exceptions, with the facts as given in the report, there is no evidence in any of them to show that alcohol would have been administered by the most ardent advocates of its use in the treatment of disease. One case of cellulitis (679) of the right leg recovered, although "the strength was decreasing, owing to the exhausting nature of the discharge, pain, and want of sleep;" but we believe it should be placed to the debit rather than to the credit side of the plan of treatment. We also believe that the directors would have done well to have withheld all such records of the hospital from public inspection. Such reports belittle the temperance cause, bespatter the face of science, and beget in the minds of many an unwonted hostility to such enterprises. That alcohol, when properly used in the treatment of disease, is beneficial, we believe has been fully established.

THE SUDDEN DEAFNESS OF SYPHILIS.

DR. SAMUEL SEXTON, surgeon to the New York Ear Dispensary, in a paper published in *The American Journal of Medical Sciences* for July, 1879, draws attention to this rare manifestation of syphilitic disease, which he describes as occurring during the secondary period of the infection. Heretofore this lesion has been generally thought to have its seat in that portion of the ear occupied by the terminal filaments of the auditory nerve—viz., the inner ear; but Dr. Sexton believes that the difficulty lies mainly in the conductive apparatus of the middle ear, and that impressions of sound fail to reach the nerve on account of anomalies of the latter. He has found a confirmation of this conclusion in the fact that the patients could hear themselves talk or sing, frequently with correctness, while no ordinary sound of the voice penetrated the ear from without. He believes, furthermore, that the ear is not invaded by syphilis in these cases from the throat *per* the Eustachian tube, but that the attack is invited, as it were, in most instances, by pre-existing hyperemia, or catarrhal inflammation of the middle ear arising from other causes.

These special invasions of syphilis are characterized by their *suddenness* and by their *severity*. Both ears are usually affected almost simultaneously, and the recorded cases seem to show that neither ear entirely escapes under any circumstances.

A rapid deposition of lymph probably takes place in these cases, causing instantaneous fixation of the ossicles. So rapid indeed is the invasion, that one patient went to bed with good hearing in one ear, and when he awoke in the morning his hearing was gone; the other ear had become deaf with even greater suddenness. The two attacks in this case were two years apart, and were both immediately preceded by a detonation compared to a pistol-shot, and extreme vertigo and vomiting. The doctor states that most dis-

travelling *tinnitus aurium* usually accompanies this disease from the outset.

The affection is not a suppurative one, none of Dr. Sexton's reported cases having that character; indeed, the visible lesions of the ear are in no way commensurate with the gravity of the disease. The inner end of the meatus is usually hyperæmic, and the epidermis exfoliates; the drum-membrane is thickened, ashy in hue, and of course lustreless; its plane is not always altered, and the Eustachian tubes are free. Dr. Sexton performed paracentesis of the membrana on some of these cases, but found no fluids in the tympanic cavity. The disease is not a painful one, as far as the ears are themselves concerned, although occasionally there was cerebral pain.

The treatment of these cases has not been attended with a restoration of hearing, but it has always occurred that the patients have failed to make timely application for relief to persons competent to recognize the importance of the aural disease. Treatment, to avail, must be most prompt, and should consist of the internal, together with the cutaneous, use of mercurials, in combination, perhaps, with the iodide of potassium.

Reviews and Notices of Books.

A TREATISE ON HYGIENE AND PUBLIC HEALTH, Edited by ALBERT H. BUCK, M.D., American Editor of Ziemssen's Cyclopædia of the Practice of Medicine, Aural Surgeon to the New York Eye and Ear Infirmary. Vols. I. and II. New York: William Wood & Co. 1879.

THIS work is in two large volumes, which contain 790 and 650 pages respectively. It consists of a series of articles written by men deservedly eminent in the medical profession, and with special reference to the private and public hygiene of different climates, conditions of soil, habitations, modes of life, and laws of the United States. It is intended not only for physicians and sanitarians, but for all educated classes.

The first volume has two parts. The first part is devoted to individual hygiene and the second to the hygiene of habitations.

The introduction includes prefatory remarks, causes of disease, and jurisprudence of hygiene, and was written by John S. Billings, M.D., Surgeon United States Army, and Vice-President of the National Board of Health. It is concise, and shows a masterly familiarity with the subject on which its author writes.

The first article in the first part of the first volume is on Infant Hygiene, and was written by A. Jacobi, M.D., Clinical Professor of Diseases of Children in the College of Physicians and Surgeons in the City of New York. This article contains valuable and practical instruction regarding the general care of the new-born child. It tells us the care that should be taken with reference to respiration and circulation, the skin, bathing and temperature, infant feeding, selection of wet-nurse, proper milk for the child, animal and vegetable substitutes for milk, intestinal digestion, mode of giving food, care of the teeth, age of schooling, etc., all of which are topics of the greatest interest and importance to the child, the mother, and the physician.

The second article is on Food and Drink, and was written by James Tyson, M.D., Professor of General Pathology and Morbid Anatomy in the University of Pennsylvania. This article includes the classification of food and drink and their physiological uses, based upon chemical composition. The subject of special foods, their adulteration and inspection, forms the subject of another chapter, which appears in the second volume, and is from the pen of another writer. After giving a classification of food, he considers first that which is direct aliment; second, indirect aliment, and then passes to the study of accessory foods, the necessity of a mixed diet, the modifications in the proportions of different alimentary principles demanded by differences in temperature and climate, the effects of cooking, the proper daily amount of food, and certain conditions and diseases resulting from the use of defective, deficient, excessive, or diseased food. Dr. Tyson's article sustains the high reputation given to the treatise by the writers by whom he is preceded.

The third article is on Drinking-water and Public Water Supplies, and was written by Professor Wm. Ripley Nichols, of the Massachusetts Institute of Technology, Boston, Mass. This article is in itself a treatise on the quantity, the quality, the question of cost, the sources of supply, artificial improvement of natural water, effects of conduits and distribution pipes upon potable water, impure ice and sanitary examination of water. There is also a bibliography. It is illustrated, contains a vast amount of valuable and practical information, and is written in an easy, flowing style.

The fourth article is on Physical Exercise, and was written by A. Brayton Ball, M.D., of New York City. This article, although presented in a most admirable manner, lacks the practical interest which characterizes those by which it is preceded. As a series of scientific lectures on the higher orders of physical exercise, such as rowing and training, and a history of athleticism, it is excellent, but it is too scientific, and looks too much into the past to be acceptable to the present generation as a popular dissertation on physical exercise.

The fifth article is on the Care of the Person, and was written by Arthur Van Harlingen, M.D., of Philadelphia, Pa., Chief of the Clinic for Diseases of the Skin, Hospital of the University of Pennsylvania. In this article are considered those means by which cleanliness, and the proper performance of the functions of the skin and its appendages are maintained, together with protection from the extremes of heat and cold and from external injury. The anatomy and physiology of the skin is presented in a brief but satisfactory and comprehensive manner. Then follow remarks on the bath, cosmetics, general bathing, clothing, beds, the care of the feet, the hands, the mouth, and the hair. The article reads like a story, and savors of plain, practical common sense.

The first article in Part II. of the first volume is on Soil and Water, and was written by William H. Ford, M.D., President of the Board of Health, Philadelphia, Pa. In this article the general subject of soil and water affecting health is studied under the three divisions of, constituents of the soil, pollution of the soil, and diseases produced by conditions of the soil. It is very elaborate, and occupies nearly 200 pages. It is one of the most comprehensive and valuable articles of the entire series. It is fully illustrated. Among the most interesting chapters are those on pollution of the soil by excreta, removal of excreta, methods of removal of excreta, the water system and

other systems, pollution of the soil by interments, by coal-gas, by surface defilement, and diseases connected with certain conditions of the soil.

The second article is on the Atmosphere, and was written by D. F. Lincoln, M.D., of Boston, Mass. For convenience the subject is studied under four heads: I. Natural Components of Air; II. Impurities; III. Meteorology and Climate; and IV. Ventilation and Heating. The chapters on heating and ventilation are fully illustrated, and contain descriptions of heating apparatus, remarks on stoves and furnaces, heating by steam and by water, and on ventilation. This article also has a bibliography. It is well written, and for the most part is within the grasp of the non-scientific reader.

The last article in the first volume is on the General Principles of Hospital Construction, and was written by Francis H. Brown, M.D., of Boston, Mass. The subject is considered mainly under the following heads: Location, General Character, Material, General Arrangement and Disposition, Arrangement of the several parts in Detail, Means of Heating, Ventilation, Drainage, and Cottage or Village Hospitals. It also has a bibliography, and is illustrated. This is a very readable article, and cannot but be valuable to those who are interested in the proper construction and management of this class of public institutions.

The book is printed with large type, on good paper, and is elegantly bound in a new style of binding. We see no reasonable ground for general criticism, and our special criticisms have already been indicated. Of the second volume, hereafter.

A MANUAL OF EXAMINATION OF THE EYES. A course of lectures delivered at the *École pratique*, by DR. E. LANDOLT. Translated by SWAN M. BURNETT, M.D., Lecturer on Ophthalmology and Otology in the Medical Department of the University of Georgetown, etc.

DR. LANDOLT'S lectures form a convenient and valuable text-book, and Dr. Burnett has rendered a good service in translating them into English. The lectures are short, and each gives a clear account of the subjects treated. Revisions and additions have been made for this volume, which increase its value. At the back are convenient tables for the study of the ocular movements and their derangements. The book is of convenient size and well printed.

On page 67, in speaking of the asthenopic symptoms due to hypermetropia and presbyopia, the author says: "The cause of these phenomena is, as you are aware, an error of accommodation." We think this sentence objectionable when applied alike to both the varieties of asthenopia in question.

On page 70, in the description of muscular asthenopia, the author says: "In order to correct the insufficiency of the internal recti we seldom have need to make a tenotomy of one of them." Treatment by tenotomy is applied to the *external recti* in this kind of asthenopia.

On page 131 is this passage: "It was Donders who first called attention to the fact that the great majority of persons affected with convergent strabismus are hypermetropes, and that for the higher degrees of hypermetropia, strabismus becomes the rule." Compare the following extracts from the Sydenham translation of Donders' work on Refraction and Accommodation:

"In general, it is not the highest degrees of hypermetropia with which strabismus is combined."—Page 293.

"In the highest degrees of hypermetropia, strabismus is rarely observed." "We have already seen that

strabismus is met with chiefly in mean degrees of hypermetropia. These belong to facultative and relative hypermetropia," etc.—Page 301.

On page 147 we read: "In passing from an illumination of a less to one of a greater intensity or inversely, it takes a certain length of time (about twenty-five minutes) for the retina to become accustomed to the altered illumination, and to put itself in harmony with it."

We think twenty-five *seconds* would be nearer the truth, judging from ordinary experience.

Reports of Societies.

WEST CHICAGO MEDICAL SOCIETY.

Special Meetings, August 11 and 18, 1879.

DR. NORMAN BRIDGE, PRESIDENT, IN THE CHAIR.

THE subject for discussion was,

THE SUMMER INTESTINAL AFFECTIONS OF CHILDREN.

DR. WM. E. CLARK thought the intestinal disorders of infancy, of summer time, were chiefly diarrhœas due to indigestion and inflammations resulting from this condition. Cholera infantum was, in his belief, of very rare occurrence indeed.

DR. H. WEBSTER JONES said, to the prostrating effects of heat must be charged many of the intestinal affections of children in summer time. The excessive heat produced a depression of the nervous centres. He thought the habit among people was to dress babies too warmly in summer. Care should be taken to cover the whole body, and warmly, especially at night, when a chill was sometimes experienced by exposure of a part; but so much covering as to induce constant sweating, as was frequently the case, was to be discountenanced. The direct rays of the sun should be avoided. The abdomen might, during diarrhœa, be covered at night with a flannel bandage. Even adults were often benefited by this procedure when subject to diarrhœa. The eruption of the teeth was one of the influences capable of irritating the nerve-centres and inducing grave intestinal derangements. Free lancing of the gums, whenever this cause seemed in operation, was called for. His habit was to cut deeply if the eruption of the teeth seemed imminent; if not, to scarify thoroughly and induce free bleeding.

Infants in summer time should have freely of cool drinks—water—whether they were sick or not. Even when vomiting frequently he would give small drinks. The physician should always see the passages from the bowels of a child sick with any intestinal derangement. Frequently food would be discovered that had been eaten several days before. He had found in fecal dejections seeds of fruit that, if parents were to be believed, had been eaten nearly a week before. Children should generally not eat the fruits from city markets. Those with seeds were always objectionable on this account, and the fruits furnished by city dealers were generally stale and acescent, and would disarrange the bowels of child or adult with delicate digestion.

Many children were unable to take milk; it habitually disagreed with them. With such it should be eschewed. Many who could not take plain milk were able to take condensed milk.

He was satisfied that at times the Chicago water was bad for sick children; whether it was due to

some contamination from the city sewers he could not say, but thought unlikely. Beef-tea for children should be very weak; in a concentrated state it did more harm than good.

For treatment when the bowels had been emptied of undigestible food, and the passages were still acecent, he had found nothing so good as a powder of one-sixth to one-eighth gr. calomel, one-quarter gr. bicarbonate sodium, one-half gr. subcarbonate of bismuth; one powder to be given every four to eight hours. Six to eight powders would generally induce less frequency of, and more normal passages. There never failed to be a slight rise of temperature and increase of thirst on the passages becoming less frequent.

On being asked his treatment of cholera infantum, he said he would treat it like cholera in the adult. For this he regarded calomel and piperine as the most valuable medicines.

DR. C. W. EARLE thought, in the management of the diseases under discussion, medication was useless without proper feeding. The most frequent of these disorders was simple non-inflammatory diarrhœa, due to improper feeding, cold, or dentition; this, if not relieved early, passed into an inflammatory state, namely, entero-colitis. It was the latter that almost alone caused the mortality. Not all sick babies could take the same kind of food. Barley-water and oatmeal-water agreed with most. Theoretically, fats were unadapted, yet practically they frequently agreed perfectly. When curd was voided undigested, milk should be wholly withdrawn for a time and rice-water substituted, or a little cream, sugar, and salt.

Medicines were not of much value. Chalk mixture was to be recommended. He would use alternatives sparingly.

What was to be done for a child at the breast of a healthy mother, the child having ten to fifteen green passages daily? Such cases were frequently encountered.

DR. T. P. SULEY thought it of great importance, in beginning treatment, to empty the bowels thoroughly by a cathartic. Some of the agents known as anti-ferments worked well to prevent decomposition of food and acecent discharges. He thought rides upon the lake very beneficial. For cholera infantum proper he suggested the use of ergot hypodermically.

DR. A. H. FOSTER had found that seventy-five per cent. of his cases of bowel troubles among children during the present season had occurred during the last week of June and the first week of August, when there was a succession of hot days. The most vigorous children got sick first—the weakly ones came down later. The stout ones sickened earliest because they took more exercise, were more exposed, and became more fatigued. Heat was the great cause of the disorders under consideration. He had found many of the diarrhœas to be complicated with malarial disorders, and this most in parts of the city where there were no sewers. He related a case of a sick infant for whom a cow was kept to supply milk, but the milk disagreed as long as the animal was kept to grass, but was borne well as soon as she was put permanently in stable and fed on hay and grain. He thought beef-tea was much inferior to mutton-tea, and condensed milk was much preferable to ordinary cow's milk. Weak solution of white of egg in water was a proper diet for many cases.

He objected to preparations of chalk mixtures in which cinnamon entered as an ingredient. The latter often contained irritating oils that would burn the lips of even an adult. A better way was to use sub-

carbonate of bismuth and prepared chalk in powders, which could be readily shaken up with milk.

DR. E. W. LEE called the attention of the Society to the value of suppositories of iodoform, belladonna, and opium, for the diarrhœa and tenesmus attending many of the bowel troubles that had been spoken of. He knew nothing that would quiet the diarrhœa and tenesmus so quickly, surely, and harmlessly, as this remedy. For a child a year old he would use in each suppository 1 grain iodoform, $\frac{1}{4}$ grain extract belladonna, and $\frac{1}{2}$ grain opium.

DR. J. S. KNOX thought alcoholic stimulants were of much more value than the remarks of members would lead one to think. He knew of no single remedy so valuable for the depression and diarrhœa among children of hot weather. He would use it freely, to the extent of several ounces of brandy or whiskey daily, if it seemed to be called for.

He thought milk would agree much better with infants if a little starch and salt were mixed with it. Salt he thought much better than sugar. Salt was a great aid to the digestion of casein, and starch prevented its coagulation into chunks of curd.

For entero-colitis he used large injections of bismuth suspended in milk, with considerable benefit.

THE PRESIDENT remarked, in reply to an inquiry of Dr. Earle as to the cause of the frequent and green passages of infants nourished by healthy mothers, that he believed the whole trouble lay in the taking of too much milk by a child that was slightly feverish and simply thirsty. These babies, by the depression of the heat or otherwise, got slight indigestion and became a little feverish; as a consequence they were thirsty, and cried and worried a great deal. They were fed enormous (to them) quantities of milk simply because they were thirsty, and must take this fluid or nothing. These children were not hungry, as they constantly appeared to be, but only thirsty. Stop their food, and give them water with a very little whiskey, and they would improve rapidly.

DR. E. INGALLS thought cases of summer diarrhœas of children were so various that no routine treatment could be given. Hot weather, to be harmful, must be continuous for several days. If half the day was cool, little harm would be done.

He thought the best treatment generally was cathartics to empty the bowels, small doses of opiates, and abstinence from food.

He thought children often did as well on artificial food as on mother's milk; it was not true that the only food for a baby was mother's milk. He would much sooner risk feeding a child from the bottle—if it could be properly attended to and nursed—than have it fed from the breast of a mother in ill health.

DR. H. M. LYMAN gave a concise account of the pathology of the different forms of bowel affections, which attracted marked attention.

There had been less real cholera infantum in Chicago since the streets had been so thoroughly sewered; there was less of it among the acclimated population than among new-comers.

In cases of real inflammation the proper treatment was mild purgatives. Calomel in small doses was the best. If there was an acid state of the dejections due to decomposition, alkalis should be given.

DR. C. W. EARLE spoke of a brief experience with the use of kumyss in bowel derangements and when other food was with difficulty digested. His experience had been favorable.

DR. D. W. GRAHAM related one case in which he had used kumyss. It was in a baby who had for many weeks had indigestion and diarrhœa. Emacia-

tion was considerable. It had frequent, but no natural passages. From the hour it began to take kumyss in small doses it became quiet; the passages became natural, and showed—what had not existed before—an absence of undigested food. So far (two or three weeks) any attempt to return to the use of the food formerly taken was followed by a disturbance of the bowels and the passing of undigested particles.

Correspondence.

CASE OF FRACTURE OF THE FEMUR TREATED BY IMMEDIATE EXTENSION FORCE ON THE DISTAL FRAGMENT.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Willie Bucher, aged 14 years, at a "picnic," August 26, 1878, clung to a scup, double-seated and having some persons in it. The scup having oscillated a few times with considerable velocity, the lad tried to get off from his clinging position. But when his feet came to the ground the scup overtook him and hit him on the anterior aspect of the left thigh, fracturing the femur at junction of middle and upper third, with a loud report. He was conveyed in a wagon home. I found the patient in great agony, the thigh in a deformed and somewhat swollen condition, with the distal fragment overlapping anteriorly. I procured speedily bandages, cotton-batting, four short, light wood splints, and some adhesive plaster; then extended and coaptated the fragments, and applied a piece of adhesive plaster on each side of the thigh, each piece being about one-third the circumference of the thigh at the point of fracture, diminishing in width down to a point four inches beyond the knee, and then overlapping them so as to form a loop below the knee to receive a piece of thin board three inches square. The adhesive straps being snugly applied, the splints, well padded with cotton batting, were applied. The widest one—for the thigh to rest upon—placed posteriorly, from the tuberosity of the ischium to the hock; another on external aspect, from a little above the hip-joint to the knee; another on internal aspect, from ramus of ischium to the knee; the other on anterior aspect, from groin to upper edge of patella; then all were tied snugly in place at four different points with pieces of narrow bandage, and a couple of narrow strips of adhesive plaster placed around them. The edges of approximating splints were separate from each other about an inch, and each tapered—becoming narrower—towards the knee, so as to correspond somewhat with the circumference of the thigh at its various points. Then a bandage was snugly applied from the instep to the groin—making some allowance, as regards tightness, for the swelling of the thigh which might be expected to ensue. The patient was then placed in a narrow bed—properly prepared—to the footboard of which was fastened a piece of thin and narrow board, a little thicker and wider than an ordinary wall-lath, which extended about eighteen inches above the level of the prepared mattress. Around this lath was placed an india-rubber ring. Through this ring and through the loop at the knee—with the square piece of board in it—was passed a piece of bandage, the ends of which were tied so as to make the strip of bandage tense enough to stretch the rubber ring; and also to make considerable traction on the adhesive-plaster strips on the thigh. This

piece of bandage was kept tense in a direct line with the thigh placed in a normal attitude, the patient being in a supine position. A greater degree of traction was required the first two weeks than afterwards. By this tension, through means of the adhesive plaster, the muscles, fasciæ, and integuments of the thigh were kept conservatively close to the fractured ends of the fragments, and the muscles were thus gently persuaded to discontinue contraction, or twitching. When the lad was completely fixed, he changed his previous tune of crying to whistling and singing, to alleviate his mother's bewailing. As the swelling of the thigh assuaged, the splints were tightened snugly around the thigh; at the end of the third week they were removed and a plaster splint put on the thigh. Extension was continued as hitherto; for the plaster, in the course of a week, became too easy a fit—from the shrinkage of the soft tissues, I suppose.

Counter-extension was procured in the usual manner, by elevating the foot of the bed by a brick placed under each of the two posts.

The extending force was somewhat similar to that in general use in such cases, and known as Buck's extension method, only that it was used at a comparatively higher level than is usual, and that it was used to make traction immediately on the lower fragment, instead of through the ankle, the leg, and the ligamentous tissues, and muscular attachments around the knee-joint, which is the usual mode.

The points of advantage by the method of immediate application of extension force to the lower fragment were recognized to be the following: 1st, collateral support to the soft tissues around the fractured ends of fragments; 2d, less force was requisite, as there was no loss of force, it being used immediately on the fragment; 3d, the direction of the force could be more accurately adjusted, as the rubber ring could be elevated or lowered, or the thigh could be elevated or lowered towards the knee quite readily; 4th, the limb, from the condyles of the femur down to the foot, were left quietly unconcerned; 5th, the thigh was the only part of the patient that it was requisite to keep in a permanently fixed or stationary condition. It may be conceded that these points are of considerable importance in treatment of an injury so serious, and which requires confinement to the bed for several weeks.

Now for the question in regard to the result: The answer is, a perfect result—no shortening, no lameness. He resumed his attendance at school when it opened after the Christmas vacation; and when the ground had become unfrozen he could walk and run in the same fleet manner as before the accident. His is the fourth case of fracture of femur treated after the same plan by me, and reported in the RECORD. The first of said cases was one of gunshot fracture, Minié-ball penetrating the femur at the greater and lesser trochanters (reported in THE MEDICAL RECORD, Vol. I., No. 20, p. 466); the second and third cases were simple fracture of femur in children (reported in RECORD, Vol. XIII., No. 5 (whole No. 378), p. 95).

Respectfully,

W. M. DORRAN, M.D.

MOUNT VERNON, N. Y., August 19, 1879.

EDISON'S STETHOSCOPE.—Edison states that he is experimenting on a stethoscope with every prospect of success. It will, however, be too expensive for general use.

RHUS-POISONING.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—There is an article in the RECORD for August 2d, also in the *Michigan Medical News* for July 25th, upon the treatment of rhus-poisoning. From the numbers of articles lately contributed upon that subject, there must be an increasing interest in its treatment.

During a long practice in the country, I had much to do with this form of poisoning, and, like many others, had some trouble in treating it until I used the sulphite of soda, and now have almost no trouble in its treatment. Cover the parts affected with soft cloths, and keep them wet with a saturated solution of the salt in distilled or rain water, adding such additional treatment as may be indicated in each particular case. I have no theory as to the nature of the disease, or the action of the remedy. I was induced to try it in these cases from my success with it in the various forms of erysipelas.

While writing the foregoing, I call to mind that in a very brief article in the "Archives of Dermatology," Vol. IV., No. 4, page 320, I recommended the sulphite of soda for rhus-poisoning. In Vol. V., No. 111, page 227, and onward in that journal, there is a systematic article, by Dr. Rosswell Park, of Chicago, Ill., upon the rhus family, its poisoning, its treatment, etc., in which a number of remedies are suggested, but the soda sulphite is not among them. I dislike to call attention to the same remedy the second time, but as it appears to have been overlooked, will offer it again for what it is worth.

A. G. SMYTHE, M.D.

BALDWIN, Miss., Aug. 20, 1879.

A WOUND SEVERING THE LARYNX AND OESOPHAGUS.

COMPLETE RECOVERY, AND SUBSEQUENT DEATH FROM HANGING.

TO THE EDITOR OF THE MEDICAL RECORD.

Dear Sir:—The following may be of interest to many of your readers:

CASE.—Wm. Barret, American, born in Ohio, æt. 32; strong and well built; living in the country about three miles from Sigourney, Keokuk Co., Iowa; while in a temporary fit of insanity attempted suicide on Oct. 10, 1878, by cutting his throat with an ordinary razor. He was discovered in the act, but was not arrested before he had, by repeated desperate cuts, severed not only the larynx, but the oesophagus. The wound was in the thyro-hyoidean space, about three inches in length, and extended back entirely through the larynx and oesophagus, and brought into perfect view the vocal cords. The hemorrhage was at first quite profuse, and faintness soon rendered him manageable. He was laid upon a bed, and Dr. S. D. Cook, of Sigourney, a very competent surgeon, to whose skill and tireless attendance the results in this case are largely attributable, was hastily summoned. The hemorrhage had very materially lessened by the time the doctor arrived, and was without difficulty controlled by torsion and pressure. The wound was cleansed and the patient placed in an easy position for respiration, which function was performed entirely through the severed larynx.

I was summoned to assist in the case on the succeeding day, and arrived with Dr. McWilliams, of Sigourney, at about 11 A.M., Dr. Cook being present

with patient. Found patient quiet and apparently comfortable, save when free amounts of mucus clogged up the larynx.

Guided by the index-finger in the wound, we were able, after some trouble, to introduce the tube of a stomach-pump into oesophagus and stomach. Using this as a guide, I with much trouble succeeded in introducing two sutures into the walls of the oesophagus, embracing its mucous coat, which seemed sufficient to maintain them in apposition. The lateral and anterior parts of the larynx were brought well together by deep interrupted sutures, which were made to embrace the fibrous coatings of the thyroid cartilage and hyoid bone. The wound was further closed by short strips of adhesive plaster, and his head tied firmly forward, with the chin well upon the superior part of the sternum. Before withdrawing the tube, we pumped into his stomach one and a half pints of good nice soup, the first nourishment or fluid that he had received or attempted to take since the accident.

For forty-two days ensuing he was sustained by nutritive enemata, save once when a small amount of soup was injected through a large-sized catheter into the stomach, his condition being that of a well-nourished person. After this time, for the space of about two weeks, he was fed by injecting soup into his stomach every day, or on each alternate one, as the doctor found it convenient to visit him, the enemata being continued. Subsequent to this latter period, however, he began to be able to swallow water and soups, not without some difficulty, as not infrequently some parts of those substances would be regurgitated or forced out through the external wound, which it had been impracticable to keep well closed by the suture before mentioned. As soon as he began to indulge in the acts of swallowing, the regular use of oesophageal bougies was commenced. The patient soon learned to introduce them himself, and was shortly able to dispense with them entirely.

The external wound was entirely healed about Jan. 1, 1879, while the one between the larynx and oesophagus gave evidence of being patent until about the 10th of the same month. His voice was but slightly, if at all, affected. The injections were generally well tolerated, and when not so, small amounts of morphine and lactopeptine were combined with them. The morphia was sometimes essential to control his inordinate thirst or hunger. His recovery was regarded by all as marvellous and complete, and he had resumed labor upon his farm when, on the 10th of Feb., 1879, eluding the vigilance of his friends, he hanged himself. No post-mortem examination was made or allowed.

This case is interesting chiefly in showing:

First.—Recovery from a wound which some surgeons had declared as necessarily fatal, claiming that it was impossible for these tubes to be thus divided without severing some of the large vessels and nerves of the neck. No ligatures were applied, nor were any important arteries cut. The hemorrhage, which was somewhat troublesome during the first closing of the wound, appeared to be from a branch of the superior thyroid and, perhaps, also one of the branches of the lingual, was readily arrested by torsion and pressure. The coats of the left carotid were exposed in the wound, so near had it come to being cut or severed. There was no troublesome œdema of the glottis or vocal cords, nor any inflammation of the bronchi, which was carefully guarded against by keeping the air of his room moistened and at a somewhat elevated temperature.

Second.—As showing how completely the demands

of nature for nourishment and drink may be answered by injections of these substances into the rectum.

Third.—In demonstrating how utterly inefficient, for the closure of a wound of this extent, are the directions usually given in most of our text-books. Neither the coarsest ligature, silk or wire sutures, would much delay the reopening of the wound from the cutting of the sutures in the tissues. Bands of common adhesive plasters placed about the neck above and below the cut, and the lower tied to a head-band, while the upper one was tied to a band about the body beneath the axilla, answered the indications as well as anything used; but this dressing was essentially a failure.†

I now think that in another case I should not hesitate to insert a silver wire through the thyroid cartilage and pass it about the hyoid bone, and thus forcibly retain the parts in due apposition.

D. SCOFIELD, M.D.

WASHINGTON, IOWA, July, 1879.

EXOPHTHALMIC GOITRE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—The very instructive clinical lecture upon exophthalmic goitre, by Prof. Jacobi, in the RECORD of the 5th inst., reminded me of how little instructive literature there is upon the subject, and induces me to report a case I have been treating the last few months:

Miss —, aged 34, teacher; nervo-bilious temperament; family history excellent, and life until twenty-nine years old most vigorous.

I took no notes of the case at the time of examining it, so, when determined to report it, addressed by mail a series of questions to the patient for the purpose of obtaining a correct and as complete a history as possible up to the time she came under my observation.

She says, in substance: "In 1874 I was engaged in teaching, and had entered into engagements to go to Persia to take charge of a female seminary; and to better fit myself for the position, determined to obtain some knowledge of scientific medicine, and devoted every moment I could possibly spare to this study, retiring at eleven and rising at four to five o'clock, to study before breakfast. Taught a large and interesting Sabbath-school class on Sundays.

"In May (1874), having already become very sleepless and lost all relish for food, I noticed, when extending my hand, that it trembled, that my fingers trembled all the time, unless supported—no jerking, a steady trembling—which gradually and constantly increased; and I soon noticed my feet trembled. It was observed I was losing flesh. About the first of June large styes appeared upon my eyelids, which compelled me to stop work and study. The trembling increased, and in the latter part of June a large abscess appeared upon my cheek.

"Was troubled at this time with a profuse disagreeable perspiration, requiring a towel to dry my face, hands, and arms. In July, the glands (evidently the thyroid) of my neck enlarged, and my eyes appeared unnatural. The physicians said my eyes appeared larger and brighter, owing to my loss of flesh and paleness. My pulse was 120 to 130. I took iron, quinine, and bromide of potash, and my appetite and strength improved for a short time; but I continued uninterruptedly to grow worse in all other respects. The menses grew less, and ceased in August for seven months. I began to have paroxysms of irregular action of my heart, with a burring noise in my neck, which, with appetite, strength, and all

the other symptoms, gradually and continuously grew worse. I was so sleepless that I sometimes thought I never should sleep again, and when I did, perspired so profusely that I was completely exhausted upon awaking. Continued to grow worse until January (1875). Had been taking tonics all the time, and aloe and salt-water baths a part of the time, and electricity had been applied to my spine a number of times with markedly injurious effect. At this time was too weak to stand; pulse so rapid that the doctor could not count it at times, but usually 140 to 160. No one believed I could live two months. In January plan of treatment was changed, and I took digitalis, quinine, and powders of chlorate of potash, and some kind of pills every night. Have at no time suffered any pain anywhere. My neck was enormously large, and my eyes (not inflamed) protruded so that they almost seemed to lay upon my cheek.

"In March was some better, stronger, and menses appeared. Was advised to go away for change. Was injured thereby, and returned in a month. Again improved, and in May could walk a little again; but in June, the weather having become oppressively warm, I grew worse, and in August menses again ceased until December following. During September the doctor concluded my disease was a form of chorea, and froze my spine with atomized sulphuric ether five times. During following winter and spring, 1876, was better, but worse again in summer. Discontinued medicine in March, because it seemed to have lost its effect upon me. Took nothing for several months, and remained in about the same condition.

"Then went to a lady, who gave me sixteen 'electrical baths' and 'a homœopathic remedy for each symptom.' Improved rapidly, and very soon could sew a little and do light housework. Came to Utah in following November, 1877, and since have worked hard at teaching continuously, except from 28th of last December to 24th of February, during a part of which time I was in Salt Lake City under your daily observation. During all that interval the symptoms all continued, but in a mild degree. In October I noticed I was more nervous, sleepless, with less appetite, and felt very weary all the time.

"In middle of November began again to suffer violent paroxysms of irregular action of my heart and a burring noise in my neck; also to suffer (as I had not before) from a severe pain in my back and in front of each hip; also violent cramps in my feet and ankles."

January 12, 1879, Miss — came to Salt Lake City and consulted me. Found her suffering from exophthalmic goitre, subacute inflammation of ovaries, and spinal irritation. Had been during the last year teaching a mission school of from thirty to sixty-five pupils in one of the neighboring settlements, under as unfavorable sanitary conditions as it is possible to conceive of—as regards overcrowding, ventilation, inconvenience of arrangement, etc.—duties very arduous for a healthy person under favorable sanitary conditions.

Present condition.—Temperature under tongue, 99°; pulse, 130 to 140, when not excited. No appetite; bowels torpid, and faces dry and hard when passed. No trouble in digesting the food taken; kidneys acting normally. Skin moist, and perspires with preternatural freedom and profuseness, she reports. Menstruates regularly, but suffers unusually constant, severe pain in back, hips, and ileo-pelvic region; soreness upon pressure in region of ovaries; exquisite tenderness over eleventh and twelfth dorsal vertebra; frequent, very severe cramps in feet and ankles; pain

and numbness along sciatic nerves; cannot sleep more than three or four hours in the twenty-four; eyes protruding so that lids can scarcely close over them; thyroid gland enlarged to four or five times its normal size; fingers, when not resting upon some support, tremble quite violently; severe paroxysms of irregular action of the heart, almost to syncope.

Prescribed *rest* of body and mind, complete as possible; a two-grain pill of monobromated camphor at bedtime every night.

℞. Quin. s., zinci ox., digitalis fol., āā gr. xxiv.; aloine, ex. bellad., āā gr. iv.; pulv. ipecac., gr. ij. M. Ft. pil. No. 24. Sig. Take one three times daily, an hour before meals.

One pill zinci phosphide et ex. nux vom. (Hammond's), three times daily, immediately after meals.

℞. Unguent. atropia, unguent. iodoform. (3 i. to 3 i.); chloroform, ʒ i.; ol. lavend., gtt. q. s. M. Ft. unguent. Sig. To be applied freely twice daily over tender ovarian region.

℞. Liniment. capsici (B. P.), applied freely every day to spine from nucha to sacrum.

Emplast. bellad., 3 × 6 in., to be worn continuously over tender part of spine.

Marked improvement commenced immediately. On account of toxicological effect of bellad. induced, I was soon compelled to reduce the proportion of atropia in the ointment to gr. iv. to the two ounces of ointment.

At the end of two weeks slept and ate well. Paroxysms of irregular cardiac action mild, and not more than once daily. No longer annoyed with the burring sound in neck. Pulse, 90 to 100. Pain in the back slight, and but a part of the time. Pain and numbness along sciatics and cramp of feet and ankles no longer felt at all. Trembling of fingers but slight; none of the feet observable. Profuse papular eruption along spine. Liniment to be suspended until eruption is healed, and then resumed a little less freely. Pill of monobromated camphor discontinued, as no longer needed.

For the two kinds of pills before prescribed, substituted the following as less troublesome:

℞. Pulv. digitalis fol., quinia. s., āā gr. xlvij.; zinci phosphidi, ex. nux vom., āā gr. xij.; pulv. ipecac., gr. ij. M. Ft. pil. No. 48. Sig. Take one pill three times daily.

Progress of improvement continues entirely satisfactory in every respect.

On the 13th of February the patient left the city to return to the field of her labor, but with strict injunctions not to go into school or perform any other labor until strength should be fully restored, and free from all morbid sensations.

At this time the thyroid gland was reduced one-fourth to one-third. Eyes markedly less prominent. Not more than three or four paroxysms of irregular cardiac action in a week. Pulse, 80. No spinal or ovarian tenderness.

Notwithstanding my strict injunctions, Miss — commenced teaching her school on the 24th of February. Reported to me a few days after, that "the only signs of disease present were prominence of the eyes, enlargement of the thyroid gland from one-half to two-thirds its size in January, when I first saw her; an occasional mild paroxysm of irregular action of heart, and strength not quite up to normal standard." She has continued the pills of digitalis and the phosphide, which has enabled her to labor hard continuously up to present time without losing, and I think she has not gained flesh.

The following is her present report: "Sleep re-

markably well—as well as I ever did in childhood. Appetite excellent. Trembling of my fingers so slight that I do not observe it for several days sometimes. The irregular action of the heart does not occur more than three or four times a week, and then very slight. My pulse 80 when I take the medicine, but when I stop it runs up to 90 or 95, and I do not sleep quite so well. My friends remark the improved appearance of my eyes. I have not been so free from all the symptoms of the exophthalmic goitre since I was first attacked. I have fifty pupils in the day-school and forty in my Sabbath-school class, and am still teaching in the old building."

I will make but two reflections: first, I have no doubt the patient would have been entirely cured before this time if she had refrained from taxing her strength; and, secondly, I believe an application of the constant (galvanic) current would have been eminently beneficial. GEO. C. DOUGLAS, M.D.

SALT LAKE CITY, UTAH, July 20, 1879.

New Instruments.

INSTRUMENT FOR SHAVING ICE FOR HOSPITALS.

By WILLIAM F. HUTCHINSON, M.D.,

PROVIDENCE.

ABOUT six months ago my friend Capt. Henry F. Jenks, a well-known inventor of this State, was in close attendance upon his sick wife in Pawtucket. Fever was running high, and Dr. Clapp had ordered iced drinks repeated frequently. About the middle of the night the supply of broken ice gave out, and the captain went down to the refrigerator in the cellar for more. After half an hour's hard work, he succeeded in shaving up a tumblerful with a big knife, expending, during the operation, large quantities of patience and ice, some vigorous language, and a piece or two of his left hand.

Returning to his post, his inventive brain set in motion that portion of its convolutions which have control of the ice-scraping function, and the handy little tool pictured herewith was the result.

With it one can noiselessly and easily fill a tumbler with powdered ice in three minutes, by holding the lump in place with one hand, and scraping with the other. I have employed it very frequently in sick-rooms, during the past summer, and commend it to the profession as a very valuable labor-saving machine in a small way.

The instrument is made of malleable iron, shaped as seen in the cut, with a cutting face of steel, set as is the knife of a hand plane. A handle projects from one side, and, when used, the lump of ice is steadied by one hand while the scraper is drawn over its surface. The box or hopper is filled rapidly and with scarcely any exertion. The whole instrument weighs about four ounces, and is about five inches in length, inclusive of handle. I often carry one in my pocket.

Obituary.

CLEMENT A. FINLEY, M.D., U.S.A.

CLEMENT A. FINLEY, formerly Surgeon-General of the U. S. Army, died on Monday, Sept. 8th, at his residence, No. 5 Woodland Terrace, Philadelphia, in the eighty-second year of his age. He was born at Newville, Cumberland Co., Pennsylvania, in 1797, and was a son of Samuel Finley, a major in the Virginia line during the Revolutionary War, and who was receiver of public moneys from the sale of public lands during the administration of Washington. Dr. Finley was educated at Washington College, Pennsylvania, and studied medicine at the medical college of Chillicothe, Ohio, graduating from that institution in 1818. In that year he entered the United States army as surgeon's mate of the First Regiment of Ohio Infantry, stationed at Baton Rouge, Louisiana. He subsequently filled the position of assistant surgeon, and was medical director in the field in the Black Hawk, Seminole, and Mexican wars. He passed eight years on the frontiers in Arkansas, Louisiana, and Florida, accompanying the commands that established Fort Leavenworth, Jefferson Barracks, and Fort Gibson, and was a member of one of the earliest expeditions to the Rocky Mountains, *i. e.*, that organized in 1834. In 1861 he succeeded General Lawson as Surgeon-General of the United States Army. In 1862 he was retired from active service, on his own application, after having served forty-four years. The commission of Brevet Brigadier-General was bestowed upon him by President Lincoln, in reward for his long and faithful services. Dr. Finley married, in 1832, Elizabeth, daughter of Dr. Samuel Moore, who was at that time Director of the United States Mint, and formerly a member of the Lower House of Congress from Bucks Co., Pennsylvania.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 17 to August 23, 1879.

JANEWAY, J. H., Major and Surgeon. Assigned to duty as Post Surgeon, Fort Columbus, New York Harbor, and Attending Surgeon, Headquarters Military Division of the Atlantic. S. O. 58, Mil. Div. of the Atlantic, Sept. 5, 1879.

SMART, CHARLES, Capt. and Asst. Surgeon. Relieved from duty in the Department of the East, and to report for temporary duty to the President of the National Board of Health, Washington, D. C., for chemical and microscopical work. S. O. 204, C. I. S., A. G. O., Sept. 4, 1879.

VICKERY, R. S., Capt. and Asst. Surgeon. By direction of the Secretary of War, the operation of so much of Paragraph 3, S. O. 195, A. G. O., Aug. 25, 1879, as relates to this officer, is suspended until Oct. 4, 1879. S. O. 208, C. S., A. G. O., Sept. 9, 1879.

STENMETZ, W. R., Capt. and Asst. Surgeon. Having been found by an Army Retiring Board incapacitated for active service, is, by direction of the Secretary of War, granted leave of absence until further orders, on account of disability. S. O. 209, C. S., A. G. O., Sept. 10, 1879.

TURRILL, H. S., Lieut. and Asst. Surgeon. Assigned to temporary duty as Assistant to the Attend-

ing Surgeon at Headquarters, Mil. Div. of the Atlantic, and to the Post Surgeon, Fort Columbus, New York Harbor. S. O. 58, Mil. Div. of the Atlantic, Sept. 5, 1879.

BANISTER, J. M., Lieut. and Asst. Surgeon. Relieved from duty at Fort Leavenworth, Kan., and assigned to duty at Fort Reno, Ind. Territory. S. O. 171, Dept. Missouri, Sept. 13, 1879.

NAVY NEWS.

List of Changes in the Medical Corps in the Navy from August 20 to August 30, 1879.

August 20th.—Medical Inspector P. S. WALES, appointed Surgeon-General U.S.N., and Chief of Bureau of Medicine and Surgery, Navy Department, vice Surgeon-General J. W. TAYLOR, retired.

August 21st.—Surgeon ADRIAN HUDSON, appointed Assistant to the Bureau of Medicine and Surgery, vice Surgeon J. B. PARKER, detached and placed on special duty temporarily.

August 22d.—Surgeon A. A. HOCHLING, ordered to special duty at Washington, D. C., attending officers of the Navy and Marine Corps, vice Medical Inspector P. S. WALES, detached.

August 26th.—Pd. Asst. Surgeon J. R. WAGGENER, detached from the Passaic and ordered to the Nautical School-ship St. Mary's, vice Pd. Asst. Surgeon B. F. ROGERS, detached and ordered to the Michigan.

August 26th.—Pd. Asst. Surgeon H. P. HARVEY, ordered to the U. S. Receiving-ship Passaic, Washington, D. C.

August 27th.—Assistant Surgeon DANIEL M. GUTERAS, ordered to the Powhatan, vice Asst. Surgeon RICHARD ASHBURIDGE, detached and granted three months' leave.

August 28th.—Pd. Asst. Surgeon H. AULICK, detached from the Naval Hospital, Mare Island, Cal., and ordered to the Tuscarora, vice Asst. Surgeon M. H. CRAWFORD, detached and ordered to the Receiving-ship at Mare Island, Cal.

August 29th.—Medical Inspector WILLIAM M. KING, ordered to the U. S. S. Shenandoah, and as Fleet Surgeon of the South Atlantic Station.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending September 13, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Sept. 6, 1879.	3	16	35	0	14	14	0	0
Sept. 13, 1879.	0	17	23	1	19	15	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis, from September 10th to September 15th inclusive, was 87, and the number of deaths that occurred was 44. The total number of cases for this year to September 16th is 1,182, and the total number of deaths 376.

HAYANA.—Latest advices from this city show that during the past week there was a decrease of 13 in the mortality from yellow fever. The number of deaths in the previous week was 65.

DR. WILLIAM A. HAMMOND.—Upon the recommendation of the Secretary of War that the findings and sentence of the general court-martial in the case of Surgeon-General William A. Hammond, referred to in an Act of Congress, approved March 15, 1878, be annulled and set aside, the President of the United States, R. B. Hayes, has, in accordance with the authority conferred by the act, ordered and the General of the Army, W. T. Sherman, has commanded that the name of William A. Hammond be entered upon the retired list of the army as Surgeon-General, to date from August 27, 1879.

HYPODERMIC INJECTION OF MORPHIA.—Dr. H. H. Kane, who has, for some time past, been collecting statistics on the hypodermic injection of morphia, would consider it a great favor if members of the profession who see this, and have had experience with the instrument, will answer the following questions:

1. What is your usual dose?
2. Do you use it alone, or with atropia?
3. What is the largest amount you have ever administered?
4. Have you had inflammation or abscess at the point of puncture?
5. Have you had any deaths or accidents caused by this instrument?
6. Do you know of any cases of opium habit thus contracted?

Where there has been an autopsy (5) please state the fact and the results obtained therefrom. All communications will be considered strictly confidential, the writer's name being used only when he gives his full consent thereto. Address all letters to Dr. H. H. Kane, 366 Bleecker Street, New York.

THE PENNSYLVANIA STATE HOSPITAL COMMISSION.—The members of this Commission, which was appointed by the Legislature to select a site in the Schuylkill coal regions for the erection of a hospital, where miners and others connected with the coal mines can receive such medical attention as may be necessary, met at the Girard House, Philadelphia, on Sept. 2d. The bill provides that the land upon which the hospital is erected shall be given free of cost, and that the State shall appropriate \$60,000 for the building. The money is now ready, and the Commission will receive proposals for the site until the 13th inst. The probabilities are, however, that the hospital will be built at Pottsville. The Commission is composed of D. A. Beckley, chairman, Bloomsburg; J. R. Eby, Harrisburg; John W. Morgan, Shenandoah; T. F. Kerns, Pottsville; Gen. Wm. Lily, Mauch Chunk; William James, Shamokin. The Commission have invited to accompany them in their visits to the various hospitals, Dr. A. H. Halberstadt, Pottsville; L. A. Lush, Schuylkill County, and L. R. Keefer, Schuylkill County. The only institutions that they visited in Philadelphia were the Pennsylvania Hospital, Hospital of the Jefferson College, Presbyterian Hospital, and Hospital of the University of Pennsylvania.

PHYSICIANS AT HOME.—We congratulate Drs. For-dyce Barker, E. G. Loring, C. R. Agnew, H. F. Walker, and Geo. M. Beard, on their safe arrival from Europe. They come refreshed for the active labor of the winter campaign.

ESERINE IN GLAUCOMA.—This drug has recently been much extolled for its beneficial effects in glau-

coma. Dr. M. Landesberg, however, in the *Philadelphia Medical Times*, cites nine cases where he had used it, and with undoubtedly injurious results. He concludes that it is not only an unreliable and worthless, but even a dangerous agent in glaucoma, since its primary results may lull the physician into a delusive security.

REPLANTING OF TEETH.—Dr. J. N. Prather, of San Francisco, Cal., writes: I notice in the August number, page 144, your paper, that "Dr. Thompson, of San Francisco, is now in London showing the profession there his new method of replanting teeth." That the minds of your readers may be further enlightened, I will state that replanting teeth is no new discovery, but has been practised more or less for ages. But the profession considers the replanting of teeth very impracticable, except in isolated cases. When a tooth is extracted the nerve is severed, and death to the tooth is inevitable; when returned to its former position, if properly anchored, it may adhere as strongly as ever to the surrounding parts, yet a tenderness will almost invariably be felt in mastication; they frequently act as irritants and ulcerate at the apex, thus becoming disagreeable and offensive, the crown turns dark, and it is thought they are more susceptible of decay.

ANTI-VIVISECTION IN ENGLAND.—The feeling against vivisection in England has been stirred up till it has become dangerous to scientific interests as well as absurd from every sensible point of view. A bill was finally presented in Parliament for the total abolition of vivisection, and it was strongly urged from some quarters. It has recently received a quietus, however, being defeated in both houses. The vote in the House of Lords was 81 to 16.

VOMITING IN PREGNANCY—COPEMAN'S METHOD.—Dr. J. T. Baldwin, Professor of Anatomy in Columbus Medical College, reports three cases of the successful application of the above method. It consists in thoroughly dilating the external os and cervical canal with the finger. In one case almost every other measure had been previously tried, and abortion was being seriously considered. Upon dilating the cervix, however, the vomiting ceased at once.—*Ohio Med. Recorder*.

PHYSIOLOGY AND HISTOLOGY OF THE CEREBRAL CONVOLUTIONS, ALSO POISONS OF THE INTELLECT. By CHARLES RICHET, A.M., M.D., Ph.D. Translated by EDWARD P. FOWLER, M.D. New York: William Wood & Co., 27 Great Jones Street. 1879.

ANALYSIS OF THE URINE, WITH SPECIAL REFERENCE TO DISEASES OF THE GENITO-URINARY ORGANS. By K. B. HOFMANN and R. ULTZMANN. Translated by T. BARTON BRUNN, A.M., M.D., and H. HOLBROOK CURTIS, Ph.B. New York: D. Appleton & Co., 549 and 551 Broadway. 1879.

Original Lectures.

CLINICAL LECTURE ON DORSO-LUMBAR MENINGO-MYELITIS FROM TRAUMATISM.

DELIVERED AT THE PHILADELPHIA HOSPITAL.

By CHARLES K. MILLS, M.D.,

NEUROLOGIST TO THE HOSPITAL.

(Prepared for THE MEDICAL RECORD.)

J. D—, 38 years of age, was a hale, strong man until six years ago, when a part of the roof of a rolling-mill fell on him, burying under it the lower half of his body. He was unconscious for fifteen minutes. No bones were fractured. He did not leave his bed for five months. For three months he could not move his legs, which were anæsthetic. He suffered with terrible pain of a deep, boring character, low down in the back. This was increased by every movement. He could, to a certain extent, escape the pain by holding his spinal column in one position, but any attempts at flexion or rotation of his trunk caused him almost unendurable suffering. The pain in the back had a tendency to radiate upward and outward, rather than downward; but two weeks after the reception of the injury he began to experience sharp darts, which came at irregular intervals, first in the right leg, and a week or two later in the left. One peculiar symptom at this time also was a feeling as if he was being drawn downward in the bed. For five weeks his bladder had to be emptied with the catheter, and for six months after this his urine almost constantly dribbled from him. His bowels were paralyzed, and so remained until within a year. Three months after the accident he began at times to suffer with cramps at different points in the legs. I cannot learn anything of positive value from him in regard to reflex disturbances, but it is altogether probable that diminution, rather than excess of reflex action, was the condition present, as the latter could not fail to have attracted his attention. Soon after he was injured he had a small bed-sore in the sacral region, but this was healed without difficulty, and he has never had any since. His toe-nails have grown less rapidly than they did when he was in good health. He says that his sexual desires and powers have so far as he can tell, remained natural; he has had two children since he became paralyzed. He has never had any eye symptoms, nor attacks of faintness, palpitation, or dyspnoea.

During the past three or four years, so far as I can determine, the changes which have taken place in his condition have not been very striking. At present he shows evidences in his face of suffering and confinement—of the want of fresh air and exercise; but otherwise he is in "good form" from his waist upward. His mental faculties are probably as strong as they ever were. Sight, smell, taste, and hearing are normal. His upper extremities show nothing wrong; sensation in them is perfect; they are thin, but not atrophied. The spinal column shows no tenderness to pressure or percussion, and no painful response is elicited by the application of ice, hot water, or a strong faradic current. He can bend his body well forward, but scarcely at all to the right or left, or backward, owing to a want of mobility in the lower half of the spine.

Many of the points so far elicited have been nega-

tive, but now, as in the progress of our examination the lower half of the body is reached, you have signs and symptoms of the most positive kind. In the first place, you observe that while, speaking broadly, both legs are paralyzed, but the left is more helpless than the right. With the latter he can perform certain large movements, as lifting the whole limb several inches from the bed, and partially flexing the thigh on the pelvis. The left is absolutely powerless. He cannot execute abduction, adduction, flexion, extension, etc., with either of the feet. All the toes are strongly flexed downward, and require much force to straighten them. Both legs are much wasted, degenerative atrophy being very marked below the knees; and the muscles here fail to respond to strong faradic and galvanic currents. Both feet are cold and have a purple, livid look, the coldness and change of color extending up on the right nearly to the knee. The tendon-reflexes are utterly abolished. I can obtain no response from patella, quadriceps, or elsewhere.

Dr. Harrison reports that his urine is alkaline, that it has a specific gravity of 1020, and contains neither albumen nor sugar, but an abundance of phosphates.

The sensory phenomena presented by this case are quite remarkable. He has not had the feeling of a cord or band around his waist, but sometimes has had some such sensation in the upper part of his right thigh. With the æsthesiometer I proceed to examine the cutaneous sensibility, first of the trunk, and then of the lower extremities. As I pass downward, pricking him with the sharp points, and inquiring whether one or more points are felt, you will notice distinct boundary lines between regions in which sensation is preserved and those in which it is partially or totally lost. The anterior, posterior, and lateral aspects of the legs can be mapped out into curious areas, according to the presence, absence, or diminution of sensibility. On the anterior surface, on the right side, partial anæsthesia begins about half an inch below Poupart's ligament; near the middle of the thigh the anæsthesia becomes total, and so continues to the toes; on the left side, in front, slight anæsthesia begins again just below Poupart's ligament, and this becomes more marked, but not quite total, from the lower third of the thigh downward. Having the patient turned over, and examining the posterior surfaces, I find that on the right side anæsthesia is total below an irregular line, beginning about the coccygeal region and trending down and across to the outside of the limb, near the junction of the upper with the middle third of the thigh; on the left side, anæsthesia is partial in the same general area, becoming more decided as the limb is descended.

Retardation of the conduction of sensation is a symptom also well shown by this patient. I prick the left foot very sharply, and find that it requires from five to six seconds for him to appreciate the sensation; on the right side it takes two seconds and a half.

Finally, he is unable to distinguish between sponges dipped in hot and cold water, showing loss of the sensation of temperature.

Before discussing the nature and the treatment of this case, I will show you another.

This second case is so similar, in many of its features, to the one on which I have just been lecturing, that it will be sufficient to call your attention very rapidly to the prominent manifestations, only dwelling upon points which were not presented by the last patient, or which are of peculiar interest.

Ten months ago the patient, an Alsatian, aged

thirty-six years, in attempting to get off the platform of a street car, with a barrel of whiting, was severely injured in the small of his back, having been struck both by the car and barrel. His history and symptoms since the injury may be condensed, as follows: Severe pain in the back for four weeks, after this gradually disappearing; paralysis of bladder and bowels, with occasional threatenings of cystitis, but this held in check by treatment; at rare intervals headaches; his mind clear, but fretful and irritable; his near vision not as good as formerly, but no other ocular or facial symptoms, and no involvement of other special senses; upper extremities show no paralysis of sensation or motion, but a little general deficiency in strength, with each hand registering only about 70° on the dynamometer; lungs and heart normal; his pulse, just taken, 72, and regular; his spine slightly prominent and very rigid in the lumbar region, but no tenderness; tendon-reflexes in the lower extremities abolished, but reflex twitchings produced by irritation of the skin outside of the areas of anaesthesia below the waist; sexual desires and powers entirely lost; both legs paralyzed as regards motion, and much wasted, especially below the knees; electro-contractility greatly diminished, and in some of the lower groups of muscles absent; both knee-joints so loose that the caps can be moved from side to side without any trouble; has had a large sacro-coccygeal bed-sore, eight inches by three and a half in dimensions, and extending equally on both sides of the median line; several smaller sores at points exposed to pressure; his feet are cold and livid, the toes in flexion and feet in abduction; since the injury all the toe-nails, except of the two large toes, fell off and grew in again; the soles and edges of his feet are in a scaly condition; urine, examined by Dr. Heller, alkaline, specific gravity 1022, very slight trace of albumen, and no sugar.

The sensory condition, in this, as in the other case, is sufficiently interesting to call for a little more extended consideration.

On the anterior surface of the right lower extremity I can map out for you a region of total anaesthesia, extending to and including the feet and toes, and bounded above by a line which begins just above the root of the penis, passes outward about an inch, then downward to the middle region of the thigh, and again outward to its external border. On the left anterior aspect the anaesthesia begins an inch or two below the knee. Behind, the anaesthesia, on the right, is below a wavering line running from the neighborhood of the anterior superior spinous process of the ilium to the sacro-coccygeal region. On the back of the left thigh is a zone of anaesthesia of peculiar shape. It is broad above, reaching across the gluteal region at about the line of the coccyx, but narrowing in its descent, until near the popliteal space, when it widens again, so that below the knee the loss of sensibility becomes everywhere complete. You have thus a sort of trumpet-shaped anaesthetic area, occupying the middle posterior aspect of the left thigh. Both penis and scrotum are also anaesthetic. I am not able to demonstrate any retardation of sensory conduction.

Summarized, the most important and striking features presented in common by these two cases are as follows: History of severe injury to the middle and lower spine; this followed at once by pains in the back and limbs, spinal rigidity, anaesthesia, and paralysis of the lower limbs and of the bladder and bowels; the condition remaining is one of motor paralysis, wasting, contractures, depressed electro-contractility,

coldness, and lividity, peculiar zones of anaesthesia, abolition of tendon-reflexes and of skin-reflexes in anaesthetic regions. This train of symptoms points to lesions chiefly of the lumbar enlargement of the cord. The painful sensation in the loins, and up the back and down the legs, the motor palsy and degenerative atrophy, the abolition of reflex excitability, and the peculiar anaesthesia, show destruction, more or less complete, of the part of the cord containing the nuclei of origin of the nerves which constitute the crural and sciatic distributions. In the case of dorsal lesion before you in the previous lecture—the lumbar enlargement below the seat of disease remaining comparatively healthy, and the vital connection of the cord with the nerves of the lower being unaffected—you saw enormously increased, instead of lost, reflex action, and but little wasting and sensory interference. You have in these cases an opposite condition.

If, in connection with the peculiar regions of cutaneous anaesthesia in these cases, you will study a schematic representation of the areas supplied by the cutaneous nerves—a diagram, for instance, such as may be found in "Henle's Anatomy"—you will discover a certain correspondence between the anaesthetic zones and the distributions of certain nerves. The lower limbs can be mapped into distinct districts, according to their nerve-supply, such, for example, as the ileo-inguinal, lumbo-inguinal, posterior cutaneous, crural, saphenous, etc., etc. My object just now is not to examine closely the question of nerve distribution in connection with the phenomena here exhibited—such an investigation would take several hours—but simply to direct attention to general facts.

Alkalinity of the urine, present in both of these cases, is a frequent symptom both of acute and chronic myelitis.

The two cases, although so similar in most respects, show some points of unlikeness, which depend, I think, upon the extent—that is, upon the exact localization—of the lesions. The second patient has had some difficulty with his vision, particularly for near objects, his upper extremities show slight evidences of permanent weakness, and he suffers at times, a point which I have not before noted, from startling seizures, in which the chief symptoms are dyspnoea, rapid pulse, palpitations, nervous tremor, burning sensations passing upward from the abdomen, a feeling of soreness and stiffness in the eyes, and great anxiety—facts which lead to the conclusion that the upper dorsal and even the cervical cord must be in a condition not absolutely healthy, rendering it liable, under various exciting causes, to states of temporary congestion. One curious feature is the difference in the sexual condition of the two men—one, strange to say, considers that he is as well in this respect as he ever was; in the other the function is abolished. It is worthy of remark that in the latter case the district of anaesthesia includes both penis and scrotum.

According to Goltz, the reflex centre of erection is situated in the lumbar cord, a view which would seem to be called in question by the sexual history of the first patient.

As to the exact nature pathologically of these cases I will not have much to say. In both instances, probably, some direct compression or crushing of the lower portion of the cord took place, this being followed at first by an acute, and subsequently by a chronic, meningo-myelitis. More or less meningeal or myelitic hemorrhage may have occurred, and general concussion of the cord may also have had something to do with the production of the symptoms.

The prognosis, at the stage at which you now see

these cases, is, of course, so far as cure is concerned, utterly hopeless.

Much, however, can be and should be done to palliate their woes. It may be of service to you in the future to discuss here the general management of such cases.

In the first place, what should be the treatment immediately after the receipt of injuries such as those detailed? Absolute rest in bed it would be almost unnecessary to enjoin, as it would follow as a matter of course. If the patient should be suffering from shock, attention must be directed to this condition. After rallying from the first general effects of the injury, unless some special contraindication should be present, blood should be taken from along the spine by leeches or wet-cups. Even the use of the lancet might be advisable in robust individuals; but usually local bloodletting would best fulfil the indications. Cold, in the form of affusion, cold compresses, or ice-bags, might be subsequently applied, although the immediate effect of such treatment should be carefully watched, as, in a few instances, from some scarcely recognizable reason, the congestive or inflammatory condition appears to be made worse in this way; and such being the case, warm, or even hot applications, would be found to do more good. The diet should be restricted. Febrifuges should be used, if called for by the state of the circulation and temperature. The bromides of potassium, sodium, ammonium, or lithium might be given with advantage, to counteract hyperemia and irritation, and the subcutaneous injection of ergotine, as recently recommended for sanguineous apoplexy, would be worthy of early trial. The bowels and bladder should be emptied, if necessary, by direct interference. If the use of the catheter is neglected, cystitis will sometimes rapidly develop. If fracture, crushing or dislocation of vertebrae has occurred, prompt surgical interference must be resorted to, and if this is successful, orthopaedic apparatus might also come into play afterward. Even trepanning the vertebrae was performed by Cline as far back as 1814, and several successful operations have been reported; recoveries, however, in cases of this kind are far from being the rule.

While the spinal affection still remains acute or subacute, the old plan of giving calomel and opium is not unworthy of trial.

Sometimes, after appropriate and active treatment, great improvement will take place, and the patient may even approximately recover; usually, however, as in these cases, a permanent paraplegia remains. When the affection threatens to become or has become chronic, counter-irritation—sinapisms, blisters, setons, or the cautery—may be called upon to help stay the downward progress of the malady. If such measures are calculated to do good, they usually do it promptly. Iodide of potassium, with the view of causing absorption of meningeal or other exudation, should be thoroughly pushed; and mercury, by inunction or otherwise, can be employed for the same purpose. Direct galvanization of the spinal column can be allowed a persistent trial; ascending currents of moderate strength being given the preference. Hydro-pathic and thermo-hydro-pathic measures come to us, strongly recommended by high German authority, for ordinary chronic myelitis, and may be tried. Both faradization and galvanization of the paralyzed extremities may be employed from time to time to keep the muscles in their best possible condition, as you sometimes have in such cases—from want of use and care—wasting, deformity, etc., out of proportion to the disease of the membranes and cord. Massage and

Swedish movements are also local means of great service to the paralyzed limbs. With the exception of the hydro-therapeutic measures, the various plans of treatment just detailed have been resorted to at different periods in the histories of our patients.

Special symptoms must be attended to as they arise. To relieve pain and spasm hypodermic injections of morphia and atropia, or suppositories of opium and belladonna will be found useful. Cystic irritation usually yields to a combination of bicarbonate of sodium, tincture of belladonna, and spirits of nitrous ether, conjoined with poultices, stupes, or sinapisms to the abdomen. In all cases of serious spinal disease a constant watch should be kept on the bladder, and the catheter promptly used if necessary. Sometimes, as the result of the constant dribbling of urine, an inflammatory condition of the glans penis and prepuce is set up, and requires special attention; cleanliness is of the utmost importance, and sedative salves and lotions may be used, or a catheter may be kept in the bladder for a time. Bed sores must be carefully guarded against; when present, and particularly if extensive, I always resort to the treatment by means of galvanic plates. The large sacro-coccygeal sore, from which the second case suffered, was quickly healed in this way. The startling paroxysms of dyspnoea, palpitations, anxiety, etc., which the second patient occasionally experiences, are similar to the seizures of which I spoke, when lecturing on a case of cervical disease, and indicate involvement of respiratory and cardiac tracts or centres. Changing the position of the patient, prompt cupping, the temporary use of respiratory and circulatory stimulants, such as belladonna, digitalis, and carbonate of ammonia, and the subsequent administration of the bromides, are the measures to which I have already called attention.

Of the use of such drugs as ergot, belladonna, and strychnia, as special remedies for myelitis, I shall have more to say in connection with non-traumatic cases of a less hopeless character.

Every effort should, of course, be made to promote the nutrition of the cord and of the individual, by the use of such remedies as tincture of the chloride of iron, cod-liver oil, phosphorus and arsenic. The patients should not be kept in bed all the time. In proper weather they should be sent into the open air in invalid chairs as often as possible.

FUCUSINE AS A THERAPEUTIC AGENT.—Fucusine has been claimed to be of much value in Bright's disease. Dienlafoy reports a series of cases to the *Gazette Hebdomadaire*, from which he concludes its action in this disease to be very slight, occasionally, however, producing some amelioration of symptoms. Its value in general is not great.

SURGICAL TREATMENT OF ANASARCA.—To avoid the inflammation and erysipelas that occasionally follow the puncturing of œdematous limbs, M. Wickens uses the following procedure: After having well oiled the limb, he rapidly makes twenty or thirty punctures with a large needle, the point just penetrating to the subcutaneous tissue. This done, he places over the punctures sponges previously soaked in a solution of salicylic acid. The sponges are to be removed, squeezed, and soaked in salicylic acid again every two or three hours. In this way several pints of fluid will drain away in twenty-four hours. In seven or eight days the wounds will be healed.—*Belgian Archives of Medicine*.

Original Communications.

NERVOUS DISEASES CONNECTED WITH THE MALE GENITAL FUNCTION.

By GEO. M. BEARD, A.M., M.D.,

OF NEW YORK.

[Continued from p. 555, June 14, 1879.]

III.

SINCE the publication of these series of papers was begun, some of the most radical of the propositions and views advanced in them—which to the profession seemed most striking and revolutionary—have received indorsement from an entirely independent source.

Mr. Jonathan Hutchinson, of London, in the *Medical Times and Gazette* for June 21 and August 23, 1879, in the course of a lecture on "Hyperæsthesia of the Eye," traverses part of the territory to which these papers are devoted. Mr. Hutchinson is both an original observer and a skilful surgeon and ophthalmologist, and he approaches the subject from the side of surgery and ophthalmology, as I am here endeavoring to approach it on the side of neurology. After stating that there are quite a number of cases of painful eye where there is aching on reading or working, where daylight annoys and artificial light is very hard to bear, and where, when complete rest is secured and strong light avoided, the aching is relieved, he states "that on examination with the ophthalmoscope nothing abnormal is found, excepting that the retinal veins are always full, in some cases there is refraction and some weakness of the internal recti, but only in a small minority of cases. With very careful examination we make a diagnosis of hypermetropia, myopia, or astigmatism, yet glasses carefully selected will give the patient little or no relief. Oftentimes, indeed, the patient complains that the glasses hurt his eyes. Tinted glasses are better, and are of some assistance."

In regard to these cases, Mr. Hutchinson remarks: First, "That these symptoms may come and go suddenly."

Secondly, "That they are frequently associated with headache and various other nervous symptoms, and are quite frequently found in students, professional and literary men, and, in general, brain-workers."

Thirdly, "That they are sometimes closely related to nocturnal emissions and sexual excesses."

Fourthly, "That in pathology this hyperæsthesia of the eye is quite analogous to spinal irritation and irritable ovary which are seen in women, and irritable testes which are seen in men, and irritability of the prostate, the coccyx, the sphincter ani, or bladder."

This venous congestion is about all that is revealed to the senses. These facts and these conclusions from facts, so far as they go, are precisely those which, during the past ten years, I have been advocating in various articles on neurasthenia and allied affections, and which have been enforced through all this series of papers.

There has been a disposition among all the ophthalmologists with whose writings I am familiar, or with whom I have conversed on these themes, to look at this form of eye-trouble more and more from the neurological standpoint; but, so far as known, no ophthalmologist or surgeon has formulated the above propositions.

Mr. Hutchinson prefers the term "hyperæsthesia" to the ordinary term retinal hyperæsthesia, for the very just reason that the latter term, retinal hyperæsthesia, does not cover the whole ground.

I prefer the term neurasthenic asthenopia to cover these symptoms, since it expresses accurately and exhaustively, and in a convenient form the real condition, and logically includes all the different varieties and sub-varieties of which Mr. Hutchinson speaks, and to which he applies the term hyperæsthesia of the eye, irritable eye, or eye-ache.

Mr. Hutchinson fully understands the dependence of these eye-symptoms (neurasthenic asthenopia) on general neurasthenia, and in regard to pathology takes the view which I published in 1868, that the real difficulty is not so much in the circulation as in the innervation, the passive congestion so often found in these states being a result of the neurasthenia, or, as he expresses it, lack of tone. This pathology is correct as applied to all neurasthenic symptoms whatsoever, and the eye is the best organ wherein to study this side of the nervous system, for the reason of the unequalled precision of the methods of examination.

If we could study spinal irritation, or cerebral irritation, or irritable testes, or breast, or ovaries, or irritability of a peripheral nerve, as in some forms of writers' cramp; or of the stomach in nervous dyspepsia; or of the auditory nerve in many cases of tinnitus; or of the prostatic urethra in seminal emissions, in spermatorrhœa—with the same instrumental precision and completeness, it is as absolutely sure as any fact in science can be, that we should find a condition quite analogous to that described by Mr. Hutchinson in neurasthenic asthenopia.

Mr. Hutchinson reports the following case:

"Mr. T—, our patient, was florid and healthy-looking, and his living depended upon his profession, and he was not in the least likely to feign or exaggerate his malady. To what cause could we attribute his hyperæsthesia? Was he out of tone, and in any respect in ill-health? He said that he could eat well, slept well at night, and was not aware of any degree of failure of health. He did not suffer from cold feet, but I noticed that his hands were mottled and somewhat livid from feeble circulation. There was something in the tone of his voice which did not suggest vigor. I found that he had been married three years, and that his wife had never conceived.

"The date of his marriage coincided with that which he assigned for the failure of his eyes. They had been, he recollected, a little irritable in the gaslight, even before his marriage; but chiefly had failed after it. I asked him if he had any suspicion that married life had not suited his health, and he at once replied that he all along suspected that the failure of his eyes had been connected with it. Yet he did not admit that in any other respects he had experienced any very noticeable ill results. He had had neither headache, backache, nor lassitude. It appeared that prior to marriage he had led an absolutely continent life, and that he had always been a total abstainer from stimulants.

"You will notice how closely in these details his narrative fits the preceding one. To complete the case, I must tell you that he never smoked, that he was liable to palpitation of the heart, and that once in his life he had fainted away.

"It is scarcely necessary to say what I recommended in the way of treatment. He was to take wine regularly, to go away from his wife for a month, and to use sea-bathing, and on his return accustom himself to extreme moderation in sexual matters.

"In considering such cases as these, one cannot but be struck with the fact that there is exceedingly little to be proved in the way of defective tone. Had the eyes remained good, neither of these gentlemen (two cases are reported) would have recognized any departure from good health."

In regard to this case of Mr. Hutchinson, I will remark, first, that the course of treatment he recommends was not by any means adapted for all cases, nor would it cure, or even permanently relieve all cases. While it is very possible that the general diagnosis of the cause was correct, that sexual excess was the source of the weakness of the eyes, yet cases of this kind are often treated with months and years of rest, without any permanent benefit. Then, again, they will not all bear wine, even in small quantities, and the majority of them will not bear tobacco well.

These cases, as has been shown in these papers, may be treated, even while they are at their work, without losing a day, oftentimes more successfully than by most protracted rest. This was clearly shown in the case reported in the second chapter of the series, where rest had failed, and the glasses and ophthalmological treatment had failed; while constant general sedative and tonic treatment, combined with local treatment, thoroughly succeeded, even while the patient was at work, using his eyes many hours every day.

Rest is a remedy that is sometimes overdone. It is a good remedy, but very often utterly fails of its purpose.

Secondly, Mr. Hutchinson was probably in error in regarding the eye symptoms as the only symptom from which this patient suffered.

This side of the nervous system—neurasthenia both of the general and sexual varieties—has now been studied long enough and closely enough to make it possible for us to state with entire certainty that neurasthenic asthenopia never or rarely exists entirely alone. In cases of this kind, careful study in complete details is almost sure to reveal more or less preceding or accompanying symptoms of neurasthenia. These symptoms are not familiar to the profession, because the profession do not study these cases, but dismiss them as victims of pathophobia.

It is a satisfaction that, after so long a struggle and waiting, and delay and misconception, so good a neurologist as Erb in Germany, and so able an ophthalmologist as Hutchinson in England, are entering upon the study of some of the phases of this most interesting and most frequent disease of modern times.

CASE XIII.—In the fall of 1878 a gentleman consulted me for the following symptoms. There were frequent attacks of intense pain and heat behind the ears. These attacks were especially severe after eating dinner and at night. There was oftentimes a feeling of fulness in the head, and decided evidence of cerebral congestion; sleep was inconstant and treacherous; he was easily kept awake by mental excitement, or by expectation of any responsibility to be incurred. A symptom that distressed him much was mental irritability. He was annoyed excessively, and out of all reason, by the play of children, or by any disturbances or unpleasant things that might arise in his family or business relations. Another evidence of his nervous susceptibility was, that he could not play a game of cards or billiards without getting nervous and having palpitation of the heart. Yet another evidence still of nervous susceptibility was that he could not bear the touch of flannel to the skin; the very thought of it would give rise to creep-

ing sensations on the spine. An interesting nervous symptom in this case was that oftentimes, in attempting to make water under circumstances of haste or excitement, as when there were persons standing behind him at a public urinal, wishing his place, there would be complete temporary retention.

Asthenopia was also a very distressing symptom; reading fine type made his eyes ache, so likewise did reading at night, or on the cars, or writing during the day. His occupation was that of a clerk in a banking house. The pulse was frequently very rapid, sometimes up to 110, to 120, rarely approaching the normal standard. At least in the times that I first saw him, so susceptible was his heart to tobacco, that very little smoking would excite his pulse and give him a sleepless night. The tongue was white and furred, and he was liable to attacks of indigestion, especially after dinner. This patient was a strong, muscular Englishman, florid in appearance, and capable of walking far and long, and enduring much physical exertion of almost any kind. And yet this man, whose appearance suggested perfect health and unusual vigor, was a typical case of cerebrasthenia or brain-exhaustion. There were no evidences whatever of myelasthenia or spine-exhaustion. There was no hypochondria in any degree, no tendency to worry over symptoms, and little or no mental depression. The history of this case bore the test of frequent cross-examination and close study. The questions to be decided in his case were: First, the cause of this cerebrasthenia, or this nervous susceptibility associated therewith in this strong Englishman; secondly, what form of asthenopia was he suffering from, and what relation had the asthenopia to the nervous symptoms in their general aspect? Was it a cause or effect, or both, of the exhaustion?

The history of the case, the results of the treatment, answered clearly both of these questions. The patient had masturbated at the age of fourteen or sixteen. After the abandonment of the habit there had been seminal emissions. For five years he had been married. He usually had intercourse but once a week. In almost all cases intercourse thus rare was followed by sleeplessness and heightening of all his nervous symptoms. Examination of the parts showed a fair development, but a prepuce somewhat elongated and redundant. It, however, was pushed back behind the gland and kept back, by my advice, with a little effort on his part. The lips of the meatus were congested, and suggested disease of a portion of the urethra. The urethra was also hyperaesthetic. There was, however, no difficulty in urination, and had never been, and no stricture, and had never been any gonorrhœa. I felt quite confident from the history of the case, and especially from the fact that the difficulty with the eyes was inconstant, coming and going with the existing causes, that the trouble was of a neurasthenic character, and that expert examination would prove it. Dr. Roosa saw the case, studied it carefully, and found, as he stated, nothing save a slight retinal congestion to account for these symptoms. Colored glasses were, however, recommended and used.

The results of the treatment have confirmed both this general and special diagnosis. The patient was at first treated generally, without any reference to the sexual organs, and with a certain degree of improvement of some of the symptoms. But nothing permanent was gained in many of the symptoms until local treatment was employed, including cooling catheters, cooling rectal electrodes, cup-sounds, with various ointments, internal galvanization and faradization, and electro-puncture. Other methods of

local treatment employed in this case were, injections in the urethra of bismuth water and witch-hazel, the local application of iodoform, and suppositories of various combinations. The effect of this local treatment was of a most satisfactory character. Even where no general treatment was employed, every symptom improved, and a majority of the symptoms have disappeared almost entirely.

CASE XIV.—I have now under observation a gentleman over fifty years of age, whose prostatic gland appears to be in a condition analogous to that of hyperæsthesia of the eye. He had been examined, before coming to me, by a distinguished surgeon, who could find no trouble with the prostatic gland; and yet, so irritable is he, that a walk of a mile or two will cause great pain in the region of the perineum and in the lower part of the back.

An ophthalmologist of reputation had carefully examined his eyes, but could find nothing the matter with them, and yet for years they had caused him intense suffering, making it difficult for him to read or use them as he desired. It is possible that the prostatic gland and the eyes are in the same pathological state: irritable and painful; neurasthenic, congested at times without being inflamed or enlarged; but none the less diseased because we cannot see the disease either with our eyes or the imperfect means of supplementing our visual deficiencies. This man had a nervous inheritance, began masturbating at puberty, abandoned the habit at the age of eighteen or nineteen, worked hard in business, almost always had cold feet and hands, married at twenty-seven, had involuntary emissions after his marriage—a case clearly enough a type of those referred to by Mr. Hutchinson, and to the study of which this series of articles is devoted.

A number of times in the course of these articles it has been asserted that functional nervous diseases are hardest to cure in the strong, phlegmatic, and vigorous, other conditions being the same. It has also been repeated again and again that irritation, abuse of the sexual organs in an unnatural or natural way, may have two very different effects—may be either local or general. When the effects are general and constitutional we have neurasthenic asthenopia, as before described, in all its forms, morbid fears in their different varieties, sweating hands and feet, headache, backache, myelasthenia, (exhaustion of the spine), with or without the spinal irritation, nervous dyspepsia, pain on pressure of the vertex, and so on, with a long row of functional nervous symptoms that make up the picture of neurasthenia.

When the effects of sexual excess are local only, we have impotence in its different grades, sometimes in its worst grade, with the symptoms of prostatic congestion, lack of desire and lack of power, premature emissions, coldness of the parts, while at the same time the constitution in general is unaffected. The man is as strong for his muscular or mental work as ever.

CASE XV.—The following case shows also how sexual debility may exist in persons of great muscular strength. A gentleman thirty-seven years of age, an athlete, powerful, and distinguished in the gymnasium, large frame, though not very tall, consulted me two or three years ago for symptoms of sexual debility, which he feared might prevent his marriage. His history was that he began masturbation at the age of fourteen, kept up the habit off and on for many years, and then he was tormented with frequent erections, though the emissions were only about twice a month. This strong, healthy man was so troubled

with palpitation, that, as he said, sitting in church he would shake the pew with the beating of his heart. After a course of sedative and tonic treatment, he at last got married, though with trembling and fear.

The day following his marriage he came to me in great distress, representing that he had made a great mistake, inasmuch as he was unable to consummate his marriage completely; he was told to wait for time to make the matter right; at the same time was treated with sedatives and tonics, and in a few days he reported a satisfactory result.

There had been in his case at one time symptoms connected with the prostatic portion of the urethra, for which he was treated with belladonna, ergot, and very small doses of cantharides.

The chief fact of interest in his case was the co-existence of this local debility of a certain grade with not only great, but enormous muscular strength. The heart also in his case was more like a delicate woman's than that of a strong man, and I see similar case continually.

I insist upon this fact, and repeat it again and again, because it seems to be new to the profession, although it has so often been referred to; it is an observation of great importance and scientific value in diagnosis and therapeutics.

The following case illustrates this latter type, where the excess makes itself felt locally, the patient remaining all the while strong.

The case also represents the satisfactory result of treatment.

CASE XVI.—A young man, thirty-three years of age, began the habit of self-abuse at the age of seventeen; after three years he stopped; then came involuntary emissions. When he consulted me, in the fall of 1878, he had the following symptoms: flushing of the face, anthropophobia (fear of society), mental depression. His anthropophobia was so profound that at times, in going into company, his heart would beat and he would feel weak in his knees. These were all the general symptoms with which he suffered.

On the other hand, he had a good pulse and an unusually strong stomach, firm muscles, and a capacity for severe and protracted muscular toil in his trade. Examination of the parts showed there was no stricture and no phimosis, although at one time he had the gonorrhœa. There were, however, clear evidences of sexual debility; there had been real aspermatism; there had been erections without any emissions to follow; at times he was utterly incapable of any satisfactory intercourse.

For several months before he consulted me he had no involuntary emissions; he was much distressed in regard to himself; especially did he want to get married. I treated him a number of months by electricity, by the methods described, using general and local applications, the electrolysis of the prostatic urethra, urethral electrode and the cooling and heating catheters, wire-brush electrode, counter-irritation of the perineum and the lumbar spine, the injection of liquor bismuthi, also the local application of iodoform.

There was no hyperæsthesia of the urethra in any part, a condition we so often see in these symptoms; he had passed through that stage. There was no difficulty in using whatever local treatment we wished. Last spring he had so far improved that I consented to his marriage. He followed the advice given, was married, and has had no difficulty in fulfilling his marital duties; the anthropophobia and other symptoms disappeared long since.

In the above case there was illustrated the very marked and very interesting psychological fact that

coitus may be unsatisfactory with a stranger even when there may be no disease whatever. Before his marriage he made an experiment of that kind with a stranger, and failed. This failure, as I told him, was psychical rather than physical, for after his marriage, which soon took place, there was no difficulty.

CASE XVII.—A gentleman, *æt.* 37, consulted me for general debility that had existed for very many years. At the age of fifteen he formed the habit of self-abuse; kept it up for some time, and subsequently went with women occasionally; but at no time, according to his statement, had there been full satisfaction; the emissions came too soon, and intercourse was possible only at long intervals. On the examination of the parts, the right testicle was found quite irritable, a condition very common. In this patient, on pressure, considerable pain was experienced; the right testicle was somewhat longer than the other; the prepuce was somewhat elongated. He was a man of large size, of great physical strength. He had very few of the nervous symptoms that so often accompany cases of this sort when there is a history such as he gave. The conjunctiva was somewhat congested, but the eyes were not sensitive. There was a degree of anthropophobia. The prepuce was also extended over the glans. He had been treated surgically, but not with any satisfaction, by means of sounds. Examination of the urine showed no albumen or sugar or spermatozoa, but an abundance of the oxalate of lime and of uric acid. Here was a case where there was a local debility, not of an absolute character, however, but of long standing and of some importance in a man of immense size and vigor, capable of much physical endurance. Every other function was well performed: the appetite was good, the digestion was good, the bowels gave no trouble, he was not usually depressed, his memory was not weakened, there was no palmar hyperidrosis so often seen in these cases, no backache, or back pain of any kind; the patient was enjoined to abstain from sexual intercourse for a while, and was treated by a combination of ergot and belladonna, by the mineral acids, by internal faradization, by cooling and heating catheters. The results in all respects were satisfactory, so that in a few weeks he was married.

I have now under care a gentleman who, with other nervous symptoms dependent on true spermatorrhœa, is annoyed by attacks of irritability of the eyes, of a most indefinite but very disagreeable character, and which compel him to rub and press upon them. A well-known oculist failed to find anything to explain the symptom. The attacks come and go in a moment. That they depend directly on the diseased prostatic urethra is beyond question, and the treatment is ordered in accordance with that diagnosis.

ANÆSTHESIA AND HOT WATER IN THE TREATMENT OF TORTICOLLIS.

By SAMUEL C. BUSEY, M.D.,

PROF. OF THE THEORY AND PRACTICE OF MEDICINE, MED. DEPARTMENT UNIVERSITY OF GEORGETOWN, WASHINGTON, D. C.

In January last (1879) a young lady, aged 17, after a prolonged exposure to severe cold, was seized with stiffness of the neck, with great soreness extending from the occiput downward over the back of the neck and upper posterior surface of the shoulders. Very slight movements of the head produced acute pain over the entire region of tenderness, but most intense along the occipital and nuchal attachments of

the trapezius muscles. She was subjected to treatment for about six weeks without any marked benefit. In March, when I first saw her, the soreness and pain were mainly located in the region of the left trapezius, and limited to that portion extending from its origin from the occipital bone down to its attachment to the spine of the left scapula. The cervical portion was very tender, felt hardened, and was thicker and larger than the corresponding part of the right muscle. Her head was as fixed as if firmly fastened in an immovable apparatus. The chin was carried toward the right and the occiput was depressed backward and to the left. The left shoulder was elevated. Contracture and rigidity of the neck part of the muscle was manifest. Pressure along the cervical portion of the spinal column, between the borders of the two muscles, gave great pain, and every effort, however slight, to move the head, either laterally or antero-posteriorly, produced the most intense suffering. The young lady was up and about the house, but sat and walked as if her head was immovably fixed in one position. When attempting to turn the head to the right or left, the whole trunk moved, and when stooping or rising the head was retained in the same relative position to the body. The same immobility of the head was maintained during sleep.

Internal medication and diverse local applications proved futile. The parents would not permit the hypodermic use of sulphate of morphia, and the young lady would neither submit to enforced movements of the head nor massage of the muscles. Electricity was faithfully and patiently tried for several weeks without any substantial improvement, and, finally, the case was relegated to time, hot weather, and expectancy. But these conservative expedients, like the preceding medicaments, proved unavailing, and I was recalled to the case July 2d. Her condition was but little, if any changed. The mother insisted that the displacement of the chin toward the right had increased.

At this consultation I suggested one of the three following methods of treatment:

The hypodermic use of the sulphate of morphia (which I have successfully employed in recent cases of lumbago and torticollis), and free movement of the affected muscles during the insensibility to pain.

The operation of Prof. Annandale: section of the left spinal accessory nerve, which I did not urge for various reasons, but mainly because I believed the trouble to be a rheumatoid affection of the muscle, and not, as in Prof. Annandale's case, a nervous disturbance.*

And lastly, the production of anæsthesia with ether, and enforced movement of the head during the narcosis.

The last was preferred by myself and selected by the parents, though sternly opposed by the patient. Several days after, with the assistance of Dr. Ashford, the young lady was completely etherized. During the insensibility I grasped the head with both hands and continuously rotated it through all of its normal motions, carrying the movements to the utmost limit of rotation. This operation was continued for ten minutes, and then the patient was left to sleep.

At my visit the next day she met me with the declaration that her neck was well. Her head was straight, chin in the median line, antero-posterior mobility quite restored and easy, but lateral rotation was somewhat painful when carried to extreme limits, and less free than natural. With directions to use friction or massage several times a day, I left the patient.

* London Lancet, April 19, 1879.

Several days elapsed before my next visit, and then it was manifest that the lateral rotatory movements were less free and more painful. I suggested a second trial of anaesthesia, but no argument could induce the patient to submit. In this dilemma I advised the use of hot water. An india-rubber hot-water bottle was secured, which, when filled with water as hot as could be borne, was firmly applied and secured over the affected muscle, and kept in position until the water cooled. This application was repeated daily during several weeks, with continuous improvement, and when last seen the cure seemed nearly complete.

I believe the repetition of the enforced movement during anaesthesia would have accomplished all that could have been expected, without any additional treatment, though it is not improbable that some soreness of the affected muscle would have remained for a brief period.

This method is to be preferred to either of the others suggested. In acute cases a single injection of the sulphate of morphia may be sufficient; but in cases of several months' duration, which are usually very intractable, the necessary and frequent repetition might produce unpleasant complications. Complete insensibility to pain produced by etherization is less dangerous, shorter in duration, and freer from unpleasant disturbances than morphia narcotism to an equal degree. In cases of permanent contracture of single or groups of muscles, it is not probable that either agent would prove valuable as a remedy; yet etherization or chloroform narcosis is the ordinary resource in cases of muscular contracture and rigidity, not, however, as curative agencies, but to secure insensibility during the performance of some necessary operation. In this case the enforced movement of the head was the object sought to be accomplished.

Section of the spinal accessory nerve has been performed in four cases of spasmodic wry-neck, with two successes. In Prof. Annandale's and one of De Morgan's cases, which were identical, the result was successful. In both cases the condition was neurotic and not, as in the case here reported, dependent on inflammatory changes of a rheumatoid character. To these different conditions may be due the varying success of section of the spinal accessory nerve.

In these cases of torticollis rheumaticus of long standing, the power and movements of the affected muscles, impaired in the beginning by the inflammatory changes and consequent pain, are, from long continued disuse, either totally lost or so perverted as to cause ugly and grotesque deformities. Restoration of the function of the muscles constitutes the essential factor in the successful treatment of the cases. This cannot often be accomplished without the aid of either anaesthetics or analgesics. Whatever may be the agent employed to secure insensibility to pain during the enforced exercise of the muscles, the changes which may have taken place in the muscular structure will demand subsequent treatment before the impaired mobility and power are completely restored.

THE ALUMNI ASSOCIATION OF THE BELLEVUE HOSPITAL MEDICAL COLLEGE holds its annual meeting and reunion at Delmonico's, Fifth Avenue and 26th Street, on Tuesday, September 30, 1879, at 8 P.M. Alumni who propose attending the meeting will please notify Lewis H. Savre, M.D., Chairman Committee of Arrangements, 285 Fifth Avenue, before that date. The price of tickets has been fixed at two dollars.

FORCIBLE DILATATION OF THE SPHINCTER PALPEBRARUM AS A MEANS OF TREATMENT IN OBSTINATE CASES OF BLEPHAROSPASM.

By HENRY G. CORNWELL, M.D.,

YOUNGSTOWN, OHIO.

DURING a two years' service as house-surgeon, Brooklyn Eye and Ear Hospital, a large number of cases came under observation where there existed, in connection with the various forms of corneal and conjunctival disease commonly found among the squalid children of large cities, a blepharospasm of most obstinate and distressing character. In some of these cases this spasm of the lids, as is frequently noticed, was of more serious import, so far as affecting the health and exercise of the patient was concerned, than the disease from which it had its origin. In conjunction with a rigorous diet, daily sponge-baths, tonics, and the usual local treatment of the corneal or lid disease, the internal administration of conium and belladonna was prescribed, counter-irritants were used, soothing embrocations to the external surface of the lids, the douche and plunge-baths were resorted to—all of which proved to be of little effect in controlling the spasm.

These unsatisfactory results led the writer to employ forcible stretching of the orbicularis. The cue to this plan of treatment was obtained in the observance of the fact, that in spasms of the sphincter and the result of fistula and fissures in this region of the body, and in affections of the female genital and urinary passages—vaginismus, etc.—such treatment proved to be of value. Forced separation of the lids was thereafter employed as a preliminary step to the ordinary local treatment, by placing the thumbs on their external surface and drawing them as far apart as was possible. Among the indoor patients this treatment was sedulously carried out, the lids were separated in this way several times a day, in all cases where the affection was found present. In granular lids its good effect was particularly noticed. Recently in private practice this plan of treatment has been more fully carried out. In some cases chloroform was given and the lids fixed widely apart by means of the spring speculum, when the patient was permitted to return to consciousness and the instrument removed. Iced cloths appeared to have a good effect when applied to the exposed globes as a local sedative. Atropinized castor oil was found to be of much benefit in irritable ulcerative conditions of the cornea, when used at such times.

This plan of treatment has proved to be, in private cases, of very marked value. In several the spasm was of most aggravating chronicity, and the treatment ordinarily resorted to in such instances was without good effect. In the following two cases immediate improvement was very noticeable:

Jennie D—, æt. 14, of Irish parents, a resident of this city, consulted the writer Sept. 29, 1878. At the time of her first appearance her eyes were heavily bandaged and her head covered with a thick veil. An examination could only be made in a room lighted artificially. By means of lid elevators the spasm of the sphincter was overcome and the globes inspected. Right eye exhibited small central ulcer of the cornea, to which a leash of several vessels was directed from the limbus conjunctivæ. Marked circumcorneal injection, and severe ciliary pain. Left eye: peripheral ulcer on the temporal side of the cornea; injection

tion of scleral and conjunctival vessels, with slight pain.

The accompanying blepharospasm was very intense; every effort on the part of the patient to open the eyes being without effect. She was very nervous and pallid from long confinement in a darkened chamber.

Treatment.—The use of atropia (4 gr. sol.), cold local baths of marsh-mallows and borax; tr. ferri chlor., after meals; daily sponge-baths, regulation of diet, etc. This treatment was strictly adhered to for three weeks without there being any manifest change in the corneal disease or the associated orbicular spasm. Oct. 20th, the patient was chloroformed, a stout spring speculum introduced, and the lids of each eye separated to their widest extent. Ice water was then permitted to drip into the eyes, and atropinized castor oil introduced. The chloroform was withdrawn after five minutes, and the patient allowed to recover from its effect. The specula were permitted to remain for a few moments in order that the orbicularis might be effectually stretched in endeavoring to overcome the resistance which the instrument offered when efforts were made to close the eyes. Two days later the patient returned, able to open the eyes fully and without much effort. The lids were ordered to be stretched apart several times a day by friends at home, and, in conjunction with the treatment originally followed, the case passed on to a favorable termination.

John H—, *æt.* 13, of Irish parentage, a resident of Niles, O., came under observation July, 1878. An examination obtained after some difficulty, on account of the extreme photophobia and spasm of the lids present, revealed chronic granular lids, slight pannus, and incurvation of lids—both eyes. His general health was much impaired, appetite poor, and skin blanched from confinement in a dark and dirty apartment for several weeks.

Treatment.—A canthoplasty was urged, to which operation his parents would not submit him. His friends were then directed to separate the eyelids to their widest extent several times a day, by means of the thumbs on their external surface. Atropia sol. (4 grs. to $\frac{5}{i}$.), and sulphate of copper used daily, general baths, coquilles, and fresh air, together with syr. ferri iodidi, and laxatives of syr. rhei and sodæ bicarb., were prescribed.

At the time of his next visit, four days later, the patient was much improved, the eyelids were more under control, and less photophobia was present. Thinking the improvement was chiefly due to the sedative action of the atropia, as an experiment the speculum was introduced and the lids of each eye fixed apart for ten minutes. Immediately upon the removal of the instruments the patient could open the eyes readily, which he continued to be able to do, and the case went on rapidly to convalescence.

These two cases taken from a number, illustrate the good effect which forced separation of the lids had in spasm of the sphincter palpebrarum, and its secondary good effect upon the nutrition of the eyeball in many of its diseases occurring during childhood.

The favorable effect of this method of treatment is perhaps due to the combined influence of the forcible and continued stretching, thus breaking up the spasmodic tendency, and to the hyperæsthesia of the ocular branch of the trifacial nerves becoming obtunded by exposure to the air.

Since the appearance of my first paper on this subject (*Observations on the Treatment of Blepharospasm*),—reprinted from *Ohio Med. and Surg. Journal*, Dec., 1878—my attention has been directed to a reprint

from the transactions of the American Ophthalmological Society, 1878—"Cases of Ophthalmic Disease in which forced Exposure to Light and Air was Salutory," by C. R. Agnew, M.D., New York, wherein this plan of treatment is introduced in the management of those affections of the eyes where extreme photophobia and blepharospasm are prominent symptoms. After relating the history of a case, Dr. Agnew says: "It is, we think, fair to suppose that the main agency in the cure was the forcible exposure of the badly nourished eye-tissues to the action of the light and air. The influx of light and contact of air would naturally awaken the dormant or perverted energies of the tissues, and quicken the reparative action. It may be said that the repeated effect of the ether would tend to neutralize morbid sensibility, and harmonize the reparative forces. We are aware of the possibility of such an agency, and would not exclude it entirely in this case. Indeed, we have often seen, in cases of phlyctenular disease, where extreme photophobia had induced the use of an anæsthetic to facilitate the examination of the offending eye, the distressing symptoms greatly lessened on the recovery of the patient from the anæsthesia. But in this case the patient had had ether employed and a canthotomy done without benefit, and subsequently got well as described. Moreover, in other instances, in older subjects, we have tried the method of forcible exposure, without the intervention of anæsthetics, and with good effect, enough to make us trust it in otherwise incorrigible cases."

A CASE OF CHRONIC DYSENTERY TREATED WITH OPIUM, RESIN, AND IPECAC.

By WILLIAM HAMILTON NAYLOR, M.D.,

OF THE BRITISH CONSULATE GENERAL, NEW YORK.

W. S—, *æt.* 38, able seaman on the British ship "Dryad," came under my care, suffering from chronic dysentery of some thirteen years' standing. The history he gave was as follows: He had been a sailor for some eighteen or twenty years, and had first contracted the disease while lying in Calcutta during the rainy season, where he received hospital treatment; had also been in hospitals in Bombay, Hong Kong, and other ports, but had never been thoroughly cured—in fact, he was what is called in marine vernacular an "hospital sailor."

When I first saw him he was in his "bunk," unable hardly to walk; had from twelve to thirteen passages a day of blood and slime; tormina and tenesmus were prominent; emaciation marked; appetite almost gone; pulse slow and feeble; tongue furred; excessive thirst; countenance denoting great anxiety and prostration; had cold, clammy sweat; was suffering from anæsthesia of legs and feet, and pins and needles in thighs.

I immediately ordered tr. opii, gtt. xxx., to be followed with pulv. ipecac, grs. xx., and hot fomentations, as recommended by Maclean, and ice to allay thirst. Twenty-four hours afterward the patient was seen, when the passages had not been controlled, and he stated that the medicine had made him "heave up." I again prescribed opium and ipecac, but reduced the latter by five grains.

The patient was seen the following day, when he stated that the medicine had not made him sick, but that there was no abatement of the dejections, and that his legs were feeling "hard." I again prescribed

as before, but in addition ordered powdered resin, in teaspoonful doses, every four hours. When I next saw the patient he had much improved, the number of passages had been reduced to about nine, and he did not feel so "tired;" his appetite had also slightly improved.

Directed that the treatment be continued, and ordered milk and lime-water to quench thirst.

From this time (four days after seeing patient, and two from date of ordering the resin) my man improved, the formication and anæsthesia rapidly disappearing, and the dejections falling from about twelve (when I first saw him) to about four per diem.

The man was finally lost sight of, having left the ship immediately he could get around.

This case presents some points of interest; firstly, as to the number of passages daily (and the man's statement was verified by the captain); secondly, by the symptoms of incipient dysenteric paraplegia; and, thirdly, by the marked improvement following the combination of Maclean's prescription with the resin.

In my practice, which is largely confined to seafaring men, and where I have unrivalled opportunities of seeing such cases, I have upon numerous occasions found marked and almost wonderful results accrue from the administration of resin.

This remedy is so simple that at times I experience much difficulty in making sailors take it, but in every instance where it has been steadily taken for four or five days, I have invariably found it beneficial; in fact, my rule is to give it solely in chronic dysentery, and I have yet to find a remedy which will in so short a period produce such satisfactory results, and I have no doubt had this man continued under my care for a short time longer, he would have been much better than he had been for years.

I might say, in conclusion, that the majority of such men are what is generally known as "hard cases," and go on periodical sprees in each port they go to, get wet, and bring all their symptoms back with renewed vigor. Of course, one gets little satisfaction from treating such patients, as it is only in rare cases our instructions are carefully followed out.

233 WEST THIRTY-NINTH STREET.

Reports of Hospitals.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

(Prepared for THE MEDICAL RECORD.)

PELVIC PERITONITIS AND CELLULITIS.

If the attack cannot be aborted the treatment is taken up regularly, the two most important indications being (1) to stop the pain, and (2) to prevent the formation of pus. With these ends in view full doses of opium and of the bromide of potassium are given together with from thirty to forty grains of quinia daily. The abdomen is painted with iodine and covered with a poultice. If the woman is plethoric the morphia is given by the mouth with neutral mixture and wine of ipecac. In some cases tonics are demanded. Occasionally the application of belladonna and blue ointment locally proves beneficial.

If the attack lasts for more than a week and the

local tenderness increases, the hot-water douche is applied to the tender cervix uteri. It is at this stage also that flying blisters are applied, beginning with a good-sized blister over the iliac region. In some cases this is all that is required. When the tumor still persists, however, another blister is put on over the womb, and then another over the other side of the abdomen, and so on until the swelling disappears entirely.

If at any time a sudden chill supervene, the plan followed is to begin all over again with large doses of quinia and of morphia.

When pus has formed tonics are administered, and among them iron especially.

In the later stages of the disease muriate of ammonia has been found to be a very excellent remedy.

The following prescription is that usually employed:

R Mist. glycyrrhizæ comp. f ʒ vi.
Ammonii chloridi. ʒ ij.
Hydrarg. chlo. corrosivi. gr. i.
Tinct. aconiti radiciis. gtt. xxiv.
M.

S.—A tablespoonful in water every six hours.

If pus has formed, and it becomes impossible to secure its absorption by medicinal means, the spot is found where the abscess is beginning to point, and an incision made large enough to admit of a free drain of pus. After aspiration the cavity is injected with a solution containing one part of iodine to nine parts of water, or, in some instances, a five per cent. solution of carbolic acid is employed.

ALBUMINOID DEGENERATION OF THE KIDNEYS OF PROBABLE SYPHILITIC ORIGIN, WITH OZÆNA AND PSEUDO-MEMBRANOUS ANGINA.

The patient was a white man, thirty years of age. When admitted to the hospital he presented the following history: He had been engaged in the manufacture of morocco for the past fourteen years, with the exception of three years spent in a butcher's shop. His habits had been good always, except when butchering, when he was intemperate. He had always been a hard-working man, and had been always much exposed to cold and wet. He had variola and measles when a child, but no other exanthematous disease. He was a married man, and had one child who suffered constantly from œdema of the feet and face. His (the patient's) father died of paralysis of syphilitic origin, and his mother of dropsy. His only living brother was healthy, but his sister had goitre, palpitation, and dropsy.

During the twelve months prior to his admission the patient had had frequent pains in the back and frequent dyspnoea. During the last four months of this time there had been a general condition of anasarca.

The appearances presented by the man upon admission were as follows: His face, neck, feet, and body were swollen. His general aspect was markedly anæmic. He was decidedly drowsy, but his intellect was good. His tongue was tremulous, coated, and flabby, and there was a membranous patch upon his uvula. The tonsils were enlarged, and the throat sore. The man's appetite was good, but there was considerable flatulence and pyrosis after meals. His bowels were somewhat costive. Respiration was attended with a loud noise in the larynx. Expiration was prolonged. The glands on the right side of the neck were swollen. He had a bad taste in his mouth, and his breath had an unpleasant smell. There was

no abdominal effusion, and his lungs seemed to be healthy. The sounds of the heart were distant and feeble, and the pulse was small and rapid. The apex-beat of the heart could be felt underneath the rib in the fourth interspace; a weak impulse could also be felt in the second and third interspaces at the border of the sternum. The upper border of cardiac dulness was a line drawn from the head of the second rib to the left nipple, and its utmost limit outwards was a line drawn directly downwards from the nipple to the fifth rib. A line drawn parallel to the linea mammalis and running from the fifth rib to the xiphoid cartilage represents the lower border of cardiac dulness, while its limit on the right was the median line of the sternum. The urine passed was dark red in color, and of alkaline reaction, and amounted to sixty-four ounces in the course of twenty-four hours. The contained albumen formed fully one-half its bulk. Its specific gravity was 1006. It contained many granular and hyaline casts.

The attending physician regarded the case as one of a very curious and interesting nature. It was concluded that the kidneys were the seat of albuminoid degeneration, with catarrhal nephritis. The underlying constitutional taint seemed to be undoubtedly syphilitic. It was argued that the angina was an outcome of the systemic disease, but that the ozena was presumably a manifestation of the catarrhal nephritis.

The case was regarded as an excellent example of those cases of hereditary syphilitic infection in which the poison is so diluted and the patient's constitution so robust that the disease does not show itself until well on towards middle life.

The indications for treatment were thought to consist in (1) the removal of the dropsy by large doses of jaborandi, and (2) in a nourishing and easily digestible diet. Buttermilk, oatmeal gruel, and light broths were ordered as foods.

After the dropsy had largely disappeared minute doses of the bichloride of mercury, with the iodide of potassium, were administered; at the same time cod-liver oil was given in combination with the iodide of iron. The patient was much improved.

THE TREATMENT OF ORGANIC HEART DISEASE.

In those instances where there is a maximum amount of cardiac force, with a minimum amount of valvular lesion, cardiac sedatives are regarded as the remedies par excellence. Veratrum viride, aconite, the bromide of potassium, and other bromides are given in small and continued doses. The need of cardiac sedatives has been found to be most marked in diseases of the mitral valve, where there is a marked tendency to hypertrophy of the left ventricle.

In these cases the diet allowed is cooling and restricted; circulatory and nervous stimulants are avoided. If the general system is plethoric a saline purgative is administered. The diet, though restricted, is not reducing, *i. e.*, the blood is not reduced in quality by it, though it is of such a kind as to be easily digested.

Where the valvular lesion has been the result of an endocarditis contracted in early life, it has often been found possible to accomplish the greatest amount of good by continuous doses of the iodide of potassium. This treatment has often cured young children with hypertrophied left ventricles and mitral disease.

In those cases of heart disease showing impairment of power, and occurring late in life, the most important item of treatment is rest and the avoidance of all muscular effort. Such patients are given beds on the ground floor and never allowed to mount stairs. In

bad cases rest upon one floor and in one room is insisted upon.

The question of diet in the treatment of heart disease has received unusual attention in the medical wards of this hospital. The diet is studied in connection with the state of the system. When the digestion is good and the blood not in abundance, the patient is allowed bread, meat, fruits, and green vegetables quite freely. Some such patients have been benefited by a lean meat diet. No patient in this condition can digest oil well. In those cases where the digestion is not good, koumyss, buttermilk, or skimmed milk is given. Where the secretions are scanty and dropsy is present the diet prescribed is exclusively one of milk. Such patients are not allowed to eat much at a time, but take food frequently and in small quantities.

Where spasms of cough and of dyspnoea occur at night the patient is only given a small amount of stimulus and liquid nourishment for some hours before going to bed.

(To return for a moment to the question of rest. In some mild cases of heart disease, gentle, moderate walking is strongly advised, but in no instance is needless running either and thither allowed.)

For the relief of the various congestions consequent upon heart disease counter-irritants are applied over the affected part. Where nervous and head symptoms predominate dry cups are applied to the nape of the neck. In pulmonary congestion muriate of ammonia is given internally in addition to the external counter-irritation. The bromides are used in cerebral congestions. When the stomach is congested, blue mass is prescribed.

When the appetite is poor, the stools insufficient, the liver tender upon palpation, and the secretions of the intestines scanty, blue pills, followed by a saline laxative, is a favorite remedy. Renal congestion is put a stop to by digitalis, together with a saline diuretic.

When the system is in an anæmic state, when the blood is watery, and when it is deficient in red globules, iron is given with advantage. Active plethora is always regarded as a counter-indication to the use of iron. The iron, when given, is administered in the form of a laxative ferruginous water, or a diuretic ferruginous mineral water.

In the treatment of the various dropsies complicating heart disease, cups, blisters, iodine painted on the surface, or iodine with croton oil is used.

In some cases the dropsy is entirely cured by rest and a skimmed-milk diet.

In cases of anasarca the most rapid relief is obtained by the use of jaborandi. Where the heart is so weak that jaborandi cannot be used, resort is had to laxatives, or warm vapor-baths.

Ascites is met by saline diuretics; hydrothorax by diaphoretics and diuretics. The patient's whole body is periodically examined physically, to see that no effusion is gaining headway.

If the dropsy becomes otherwise unmanageable, resort is had to operative measures, and the skin is tapped—a number of minute punctures being made in the skin with delicate needles.

Where there is a faulty condition of the nervous ganglia of the heart, associated with the organic disease, digitalis is employed with great benefit. Where one preparation of this drug is not borne by the stomach, another is substituted. Where the separate contractions of the heart are evidently inefficient, and the pulse is weak and small, digitalis has proved itself an unrivalled remedy. The usual dose of the

tincture is gtt. x.; of the infusion, f ʒi.; and of digitalin, gr. $\frac{1}{60}$ every three hours.

Belladonna has been of service where the heart's action is strong but irregular. Where the heart muscles are weak and passive congestions rife, strychnia and quinia are prescribed.

Progress of Medical Science.

CHLORIDE OF BARIUM IN THE TREATMENT OF INTERNAL ANEURISM.—A case of abdominal aneurism successfully treated by chloride of barium is reported by F. Flint, M.D. The patient, a married lady, aged sixty-five, was first seen in February, 1878, and the diagnosis was confirmed by several professional gentlemen, including Mr. J. W. Teale. For five months Tufnell's treatment was tried, and rigidly carried out, without producing the slightest improvement. Chloride of barium was then selected as a probably useful remedy, and given in doses of one-fifth of a grain three times a day: after three or four weeks the dose was increased to two-fifths of a grain, and maintained at this point during the remainder of its administration, with the exception of a very short trial of three-quarters of a grain. Within a fortnight after the use of the chloride was begun there was a marked diminution of throbbing, which was both subjectively and objectively evident; after nearly five months' continued use of the drug, the tumor was so reduced that it could scarcely be felt, and only a faint systolic murmur could be heard. Four or five months after the discontinuance of the drug, there was still a slight systolic murmur, but no throbbing; the pulse was about 72, and it had entirely lost its unnatural tension.

Mr. J. W. Teale has recently seen the case again, and expressed himself highly gratified with the change in the patient's state. So that testimony can be borne by an independent, trustworthy practitioner to the accuracy of the diagnosis and the reliability of the improvement.

In large doses, two drachms and upwards, chloride of barium paralyzes the heart and great blood-vessels; in doses of about a grain it is a stimulant: the dose selected was less than the stimulating dose, and Dr. Flint thinks he might have done better by adhering to the first amount given (gr. $\frac{1}{2}$), instead of increasing it. The drug appears to have a decided affinity for the muscular coat of the arterial system, and it probably restored tone to the diseased portion of the arterial coat, and thus gave rise to consolidation of the weakened wall. In the case in question, the aneurism appeared to be fusiform rather than sacculated, and therefore deposition of fibrin could not very readily take place. Perfect rest is essential to any medical treatment, and it would be well to try Tufnell's diet alone at first, and afterwards to adhere to it as far as possible during the use of the drug.—*The Practitioner*, July, 1879.

POWDERED ALOES IN THE TREATMENT OF WOUNDS OF JOINTS.—Dr. E. Millet used powdered aloes in a case of severe injury to the fingers with most gratifying results. The second phalanx of the index-finger was torn from the first, a strip of skin about a centimetre in width, and the deep flexor tendon being all that served to unite them. Recollecting that the veterinary surgeons used powdered aloes with good success in the treatment of wounds of joints, Dr. Millet

placed the injured finger on a splint, and covered the wound with the drug. Twice, only, in a fortnight was this simple dressing renewed. The wound healed kindly without any local pain or inflammation, and almost without suppuration. When the splint was removed there was considerable motion in the joint, and it is thought that time and daily use will restore it to its full power. It is thought that the aloes acts in two ways—by assisting cicatrization and by excluding the air; to the latter action was probably due the almost instantaneous cessation of the acute pain from which the patient was suffering before the application. The simplicity of the dressing, requiring but infrequent renewing, is not one of its least recommendations.—*Revue Médicale*, July 26, 1879.

ANEURISM OF THE AURICLE OF THE RIGHT EAR.—M. Weinlechner records a case of aneurism of the auricle of the right ear, for the relief of which he ligated the primitive carotid. Six months later the skin of the affected part had returned to its normal condition, and the patient was free from the tinnitus aurium, and the headache from which he had suffered for a number of years.—*Gazette des Hôpitaux*, June 28, 1879.

PYONEPHROSIS WITH EXCRETION OF FLUID FAT AND HEMATOIDIN-CRYSTALS IN THE URINE.—Ebstein, of Göttingen, reports this remarkable case: The patient, a woman, was attacked suddenly with fever and pain, attended by the development of a tumor in the left side of the abdomen. The acute symptoms passed off in a few days, but seventeen days after the outbreak of the affection hæmaturia set in, accompanied by pain, at first referred to the tumor and afterwards to the left ureter and the bladder. The sediment, at first consisting of pure blood, later on became more and more purulent, and then numerous fat-drops and hæmatoidin-crystals were observed in the urine. The urine, at first scanty, steadily increased in quantity, and at the same time the tumor progressively diminished in size, but it had not entirely disappeared at the time the patient left the hospital. The tumor was thought to be due to a pyonephrosis of the movable left kidney. The excretion of fat persisted for several weeks. It occurred in the form of clear, golden yellow drops floating on the surface of the fluid; after the urine had stood for some time they presented signs of coagulation and crystallization. They consisted of a mixture of the oleate, margarate, and palmitate of glycerine. The urine contained also hæmatoidin-crystals, a very rare constituent; they were found along with fat globules in the ragged flakes that were passed abundantly in the urine, and also mingled with the fat floating on the surface of the fluid. Prof. Ebstein ascribed the fat to a fatty degeneration within the tumor, and the hæmatoidin-crystals to the preceding hemorrhages. He refers to a case reported by Mettenheimer, in which, after a sudden attack of hæmaturia, accompanied by the development of a tumor in the region of the kidney, fat drops were observed in the urine for several days, but no hæmatoidin-crystals were found.—*Berl. Klin. Woehent.*, July 7, 1879.

THE TREATMENT OF METRORRHAGIA BY CAFÉ NOIR.—Després reports two cases of intractable metrorrhagia, in which he prescribed six cups of strong infusion of coffee in a single day, with perfect and immediate success, the hemorrhage ceasing within twenty-four hours. He thinks the caffeine contracted the heart and blood-vessels.—*Medical Times*, August 2, 1879.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 27, 1879.

MEDICAL TEACHING.

An eminent member of our profession has said that the knowledge which a medical student obtains while in college has but little practical value.

Another eminent member of the profession has said that a man is just ready to begin the study of medicine after he has practised it five years.

These are the opinions of two men who have seen much of medical students—one has been a public teacher in medicine for many years—and they are the result of mature and prolonged experience and observation.

The first statement is based on experience obtained in one of the first medical colleges in this country, together with careful observations respecting how much of the knowledge then acquired was subsequently of practical value in the diagnosis and general management of disease. He maintains that the general plan of medical teaching is radically wrong and practically worthless, for the reason, that at no time during the entire course of public instruction does the student receive instruction in the methods of observing morbid phenomena and the sources of error in investigating the histories of cases. In other words, the medical student may go out from his alma mater bending under honors and laden with classical knowledge regarding the phenomena of disease, yet when he approaches the bedside of the sick he finds that his well-treasured and finely-spun digest of medical lore cannot be used; that he is obliged to begin and study for himself, and that his success depends largely upon his ability to work out his own salvation.

In this sweeping belief there are some grains of truth. We believe that it is the uniform experience of medical men, when they first enter into practice, to find that they are called to manage cases which "are not described in the books," and lack all the classical appearance which, from their teaching, they have been

led to believe nearly every case possesses. Such cases, however, go to make up the mass of business done by the general practitioner, and in a certain sense it may be said, and truthfully too, that his whole course of medical instruction is of no assistance in solving these perplexing problems, because he has not heard anything concerning them in the lectures, nor can he find any description of them in the books. However, to unravel the thread we have only to ask, Is not the young practitioner more competent to undertake the task of reaching the unknown quantity in such cases than if he was not the possessor of his school knowledge? We think he is; but with his five years of experience contemplated in the second statement, he is doubtless far better prepared to pursue his studies and examine his cases than when he first commenced.

It is not disrespectful towards medical colleges to say that their course of instruction is not all that is desired in order to fulfil the best interests of the medical profession. Deficiencies exist—but no more, perhaps, than belong to other organizations of like character. Errors, however, are being slowly corrected and wants supplied, a fact which betokens a healthy root, and as the pruning and grafting goes on the fruit will certainly improve in quality. We are near the time when medical colleges commence their regular course of instruction, and there are one or two points to which we wish to direct attention, believing that a careful consideration of them will do much to disprove the first statement with which we began, and also to disarm the second.

In the first place, and in general, medical teaching to medical students is not sufficiently elementary.

An eminent, old, and successful teacher in medicine has said that each year he makes his instruction more and more elementary, simply because he has found, by experience, that it is that from which the student derives the most practical benefit. An eminent, old, and successful teacher in surgery has said that when he first began to teach, he studied to make his lectures finished rhetorical efforts, and sought especially for rounded sentences. To his surprise, chagrin, and profit, when he came to examine his students for the degree he found that they knew little or nothing concerning surgery. In the experience of these two men there is sufficient to illustrate our meaning, and it is this: that he who instructs medical students in elementary principles, and does it in the simplest language, is the most successful teacher, providing he enforces by demonstration what he has to say. To dwell on subjects difficult to acquire, which are speedily forgotten, and have no practical value when acquired, is not only an unprofitable consumption of the time of the student, but it does him a lasting wrong inasmuch as it gives him knowledge he does not need, and deprives him of a personal share in clinical study and in an acquisition of that knowledge

of disease and remedies which is to serve him for immediate use and in emergencies.

This brings us to the second point to which we direct attention, and that is, the power of demonstrative teaching. A large portion of the medical teaching of the present day lacks the force of demonstration. It is descriptive rather than demonstrative. There is nothing that does more toward correcting special views and operations and the exaggerated and faulty notions which get into the minds of medical students, and also medical men, than demonstration. If the student can see a typhoid ulcer, a micrococcus, the fundus of the eye, an inflamed tympanum, a urinary cast, a urinary crystal, a vesico-vaginal fistula; if he can touch a displaced uterus, a prolapsed ovary, an abdominal tumor; if he can hear a cardiac murmur, a crepitant, subcrepitant or bronchial r le, a pericardiac or pleuritic friction sound; if he can see his teacher map out by percussion the heart, the liver, the spleen, the fluid in a pleuritic cavity, or the consolidated portion of a lung, it will do more toward imparting instruction which will prove of value to him when he goes out to meet the maladies of human life, than hours of unaided talk or reading. Even the illustrations with which text-books abound cannot be fully appreciated, and are very liable to give erroneous impressions until the original has been seen. What sways and convinces an audience, even of experienced medical men, more than ocular demonstration? The teacher who simply stands by a patient in a clinical amphitheatre and discourses learnedly, and correctly it may be, regarding the precordial triangle, the physical signs of subacute pleurisy, or ascites, a foreign body in the eye, the appearance and feel of a chancre, of a urethral stricture, an abdominal tumor, scabies, eczema or varicella; tells of the manner in which a roller bandage should be turned in order to look elegant and fit well, of how a plaster-of-Paris dressing should be applied,—and makes no effort to demonstrate these things, is thoroughly untrustworthy, and should not be tolerated by the ordinary medical student. Such teachers have too much the appearance of those who teach, or rather meagrely go through with a formality in teaching, simply to obtain the money that a medical student may have. The number in the latter class we charitably believe is small; but they are like a *non compos* on a mountain, to whom everybody looks small, and who looks small to everybody else.

Dr. Andrew Clark, from whom our readers heard when he made his visit to this country, in his address before the Section in Medicine of the British Medical Association, refers to this point, and notes it as one of the deficiencies in the present system of medical education. He says: "Medicine is an art, and its end is practice, and the worth or worthlessness of any system of education must be tried by the degree in which it helps or hinders this end." One of the vicious methods

which the system sanctions is that "the student is told and not taught." "The teacher, instead of making the student follow him step by step in his methods of observing, collecting, comparing, testing, and recording facts and of reasoning thereon, leaves them to be learned by being described, forgetful that they can be learned only by being practised."

When in the fulness of time it is insisted that medical students shall receive more thorough instruction in the practical elements of the science and the art of medicine, and shall be made to share in clinical study, the people will be furnished with more medical men who possess trustworthy knowledge regarding the powers of nature and of art in bringing about recovery from disease. The knowledge then acquired as a student will be of positive value as a practitioner of medicine, and the first five years of professional life will bring with them a reward commensurate with the labor performed.

THE CARE OF HABITUAL DRUNKARDS.

The question of what should be done with habitual drunkards is still a very unsettled one, and is rightly claiming the attention of both medical and legislative bodies. In this country the prevalent opinion amongst those especially interested in the matter is, that inebriety is a disease (rather than a vice), and that its victims should be regarded and disposed of in much the same way as insane persons. Inebriates, it is claimed, are not in many cases to be considered responsible for their actions, and should therefore be taken charge of by the State and placed in asylums appropriate for their treatment. There are, we believe, but two asylums for inebriates in this country where the theory that drunkenness is a disease is not adopted as the basis of management; and we have several States where this placing of the inebriate on the same footing with the lunatic has been more or less rigidly adopted. In Connecticut, the idea is completely embodied in the law, and habitual inebriates can be committed by the court, upon proper evidence, to an asylum. In this State the law is less radical, nevertheless it provides that persons who have become incompetent, through habitual drunkenness, to take charge of their affairs, shall be put in charge of the court. Several other States have laws, which, in like manner, class the victims of alcohol with idiots, lunatics, and persons of unsound mind.

Instigated by the general revival of interest in the temperance question in England, and perhaps partly by our progress in the matter, the British Medical Association appointed a committee, a year ago, to secure some legislation upon this subject of habitual drunkenness. There were then in England no laws in regard to the care of inebriates, and but few private asylums, these being such as only the wealthier classes could patronize. The question of greater provisions for, and compulsory treatment of inebriates, was

brought before Parliament at its last session. After much struggling a bill was passed which provides for the establishment of inebriate asylums, granting, however, only a voluntary entrance to them. An inebriate can commit himself, and he must commit himself for a certain period of time; but he cannot be compelled to enter the institution. This result is by no means all that was desired or sought for; but no more could be obtained, and it is hoped that it may be the entering wedge for something better in the future. What the committee wished, and will continue efforts to obtain, is the establishment of asylums to which every inebriate who has reached the stage when his appetite is supreme and he is unable to take charge of his affairs, shall be at once committed for a considerable period of time.

While it is undoubtedly a fact that the weight of medical opinion is in favor of considering and treating inebriety as a disease, and of providing compulsory care for its subjects, there is some very high authority upon the other side. Dr. Bucknill, who visited this country in 1875 and went through our lunatic and inebriate asylums with a free lance, declares drunkenness to be a vice and only the *cause* of disease. He speaks depreciatingly of the great prominence usually given to heredity, and looks upon the ordinary inebriate asylums as institutions which only coddle drunkenness and patch up the evil they pretend to alleviate.

The practical importance of definitely determining whether drunkenness be a disease, or only a cause of disease, is not so great as specialists would have us think. When a man has become a dipsomaniac, has ruined himself and family, and is both a nuisance and a danger to society, he needs to be taken care of without regard to fine pathological distinctions. Before settling the pathology of inebriety, therefore, we can urge the propriety of legal provisions for its victims. The British Medical Association is working in the right direction. Present asylums may be poor, and the difficulties of obtaining proper legislation for inebriates great, but this does not affect the fact that persons whom alcohol has unfitted for every social and domestic duty, and who are degraded and made violent by its indulgence, need and should have State or local supervision, accompanied by such measures as will not punish and still further degrade, but will tend to cure and restore them to usefulness.

THE NEW YORK PATHOLOGICAL SOCIETY.—The third volume of the Transactions of the Society is now ready.

DR. GILMAN KIMBALL.—On the evening of September 30th Dr. T. Gaillard Thomas, of this city, gave a brilliant reception in honor of Dr. Gilman Kimball, of Lowell, Mass., who is the oldest ovariotomist now living in this country. A large number of eminent members of the profession were present.

Reviews and Notices of Books.

A TREATISE ON HYGIENE AND PUBLIC HEALTH. Edited by ALBERT H. BUCK, M.D., American Editor of Ziemssen's Cyclopaedia of the Practice of Medicine; Aural Surgeon to the New York Eye and Ear Infirmary. In two volumes. New York: William Wood & Co. 1879.

THE second volume, like the first, has two parts. The first is devoted to Occupation, and the second to Public Health. The first article in Part I. of the second volume is on the Hygiene of Occupation, and was written by Roger S. Tracy, M.D., Sanitary Inspector of the Board of Health, New York. Dr. Tracy considers his subject under three heads: I. Occupations involving the introduction of deleterious matters into the body; II. Occupations involving exposure to conditions that interfere with nutrition; and III. Occupations involving exposure to mechanical violence.

There are some very interesting statements in this article, particularly those relating to the inhalation of gases and vapors. It is well written, and has a bibliography.

The second article is on the Hygiene of Camps, and was written by Charles Smart, M.B., C.M., Assistant Surgeon United States Army. The camps of military and civil life are considered in this article, which is illustrated, and is written in a practical style. The transmission of malarial fever by means of drinking-water is spoken of here, and the writer also throws a shadow of doubt over the reported prevalence of typhoid fever—"simple or masked by malarial concomitants"—among our troops during the late war. He also believes that the germ theory does not involve such exclusiveness as forbids the possibility of a *de novo* origin of typhoid fever.

The third article is on the Hygiene of the Naval and Merchant Marine, by Thomas J. Turner, M.D., Medical Director United States Navy. The writer says that naval hygiene has for its province all that concerns the health of a special class whose occupation is pursued under conditions which are so arrayed as to be in almost absolute defiance of all sanitary laws. Nevertheless it is among these men that preventive medicine has demonstrated its economic and social value, and these are exhibited in his remarks on the ship, the sailor, the air, the water, the food, the clothing, the light, the sleep, the discipline, and the diseases peculiar to ship-life. It has a bibliography.

The Hygiene of Coal Mines is the title of the fourth article, and was written by Henry C. Sheaffer, Coal Editor of the *Miners' Journal*, Pottsville, Pa. In this we find a sketch of the work, habits, and mode of life of the working miner, and the conclusion is reached that coal miners have as good average health, as fair percentage of longevity, and as low a death-rate as any other class of manual laborers.

The fifth article is on the Hygiene of Metal Mines, and was written by Rossiter W. Raymond, Ph.D., Editor of the *Engineering and Mining Journal*, New York City. This is a short article, in which the writer refers to physical exertion, air, and temperature, and gives some general conclusions, and also makes references to metallurgical works. It is the last article in Part I. of Vol. II.

The first and second articles in the second part of the second volume are on Infant Mortality and Vital Statistics, and were written by Thomas B. Curtis,

M.D., of Boston, Mass., Surgeon to Out-patients at the Massachusetts General Hospital. In the first article the writer refers to the methods of estimation, the predisposing causes to infant mortality, and the principal diseases of infancy which especially affect the rate of mortality.

In the second article is a large accumulation of valuable statistical material.

The third article is on Adulteration of Food, and was written by Stephen P. Sharples, S.B., of Boston, Mass., Chemist, Inspector of Milk for the City of Cambridge. In this article we find a concise account of the apparatus and appliances found useful in this branch of research, the adulterations of the more common articles of food, with the methods of detecting the same. The article has a bibliography.

The fourth article is on Public Nuisances, and was written by Roger S. Tracy, M.D., Sanitary Inspector of the Board of Health, New York. This subject is discussed under the following heads: I. Offensive trades, such as the keeping and the killing of living animals, the storage and the handling of mineral matters, carpet-cleaning, street-sweeping, etc.; II. Offensive processes, such as fat-rendering, bone-boiling, varnish-making, smelting, assaying, distilling, etc.; and III. Other nuisances, such as dead bodies, privy-vaults, cemeteries, diseased animals, prostitutes, etc. The article is exceedingly interesting; it has a bibliography, and also a few illustrations.

The fifth article is on Quarantine, with reference solely to seaport towns, and was written by S. Oakley Vander Poel, M.D., Health Officer of the Port of New York. It is from the pen of one who has had large experience, and is familiar with the subject on which he has written.

The sixth article is on Inland Quarantine, and was written by S. S. Herrick, M.D., Secretary of the Louisiana State Board of Health. In the consideration of this subject the author refers solely to yellow fever and cholera. Here we find an interesting discussion of the origin of yellow fever and the legislation necessary for the protection of communities.

In both articles on Quarantine the value of preventive medicine is recognized.

The seventh article is on Small-Pox and other Contagious Diseases, such as scarlet-fever, measles, and whooping-cough, and was written by Allan McLane Hamilton, M.D., Sanitary Inspector of the Board of Health, New York, and Bache McE. Emmett, M.D., New York City. This is a brief article, and is well adapted to a work of this character.

The eighth article is on the Hygiene of Syphilis, and was written by F. R. Sturgis, M.D., Clinical Lecturer on Venereal Diseases in the University of New York, etc. This is a five-paged article, in which the subject is considered under the following heads: 1. The contagious character and danger resulting from the disease; 2. Its effects upon health and longevity; and 3. The means adopted for its control.

Disinfectants are considered in the ninth article, and it was written by Elwyn Waller, Ph.D., Chemist to the Metropolitan Board of Health, New York. After an appropriate introduction the different agents in use for disinfection, such as heat, bromine, sulphurous acid, metallic salts, etc., and their application, are considered.

The tenth article is on Village Sanitary Associations, and was written by Roger S. Tracy, M.D., Sanitary Inspector of the Board of Health, New York. This is a brief article, and it hinges on preventive medicine.

Dr. D. F. Lincoln, M.D., of Boston, Mass., wrote

the eleventh article, which is on School Hygiene, and in which the subject is treated under the heads: Site and points in construction of the houses, heating and ventilation, drainage, contagious diseases, hygiene of the eye, desks, seats, mental application and bodily exercise. This article has a bibliography, and although the last in the volume, it is not the least in value. If these two volumes could enter every house, and there be studied, an influence for good would be exerted which is beyond ordinary estimation.

PHOTOGRAPHIC ILLUSTRATIONS OF SKIN DISEASES. By GEORGE HENRY FOX, A.M., M.D. Complete in Twelve Parts. Parts III. and IV. New York: E. B. Treat, No. 805 Broadway.

PART III. contains descriptions and illustrations of Fibroma pendulum, Varicella, Zoster pectoralis and lumbalis, and Eczema universale.

PART IV. contains descriptions and illustrations of Leucoderma, Chromophytosis, Favus capitis and corporis, and Eczema cruris.

The illustrations of fibroma and varicella are very good, those of zoster poor, and that of eczema universale excellent, so far as extent goes, but only moderately good for conveying a correct impression regarding the actual appearance of the disease.

The illustrations of leucoderma and chromophytosis are very good, those of favus still better, and that of eczema cruris is well calculated to convey an incorrect impression. The skilled artist has in some instances, it seems to us, used his brush a little too freely.

A CLINICAL TREATISE ON DISEASES OF THE NERVOUS SYSTEM. By M. ROSENTHAL, Prof. of Diseases of the Nervous System at Vienna. With a Preface by Professor Charcot. Translated from the author's revised and enlarged edition, by L. PUTZEL, M.D. New York: Wm. Wood & Co. Svo. Pp. 278. 1879.

WE have in this book another and very valuable addition to "Wood's Library of Standard Medical Authors." The book, though essentially a clinical treatise, gives a very complete account of the pathology of each disease, as well as of such physiological points as are necessary to an understanding of the symptoms. The present volume is the first of two, and includes only the organic diseases of the nervous symptoms. These are treated of in a clear and concise manner, without theorizing or flourish of rhetoric; nor is the book encumbered with extraordinary cases. The chapter on tumors of the brain is especially good, and under the head of symptomatology the author covers nearly the whole ground of cerebral localization. In the matter of treatment, especial attention is called to the value of hydro-therapeutics in chronic nervous diseases. Such measures are steadily gaining ground in Europe as helps in treatment, and their prominence in the present work will add much to its value. In his preface, Prof. Charcot compliments the author on the directions given in the book regarding the use of electricity, and admits that Dr. Rosenthal has taught even the countrymen of Duchenne some useful indications. The translator has done his work well, and made the book into very good English. He has added quite a number of illustrations, not contained in either the French or German editions, and has shown excellent judgment in the selection of such cuts as would be most likely to help the student.

THE ACADEMY OF MEDICINE in Paris has awarded a prize of \$400 to M. Burg for his researches in metallo-therapy.

Reports of Societies.

BRITISH MEDICAL ASSOCIATION.

FORTY-SEVENTH ANNUAL MEETING.

Section in Surgery.

W. K. TANNER, M.D., F.R.C.S.I., PRESIDENT, IN THE CHAIR.

WEDNESDAY, AUGUST 6TH.

THE DIAGNOSIS AND TREATMENT OF JOINT DISEASES IN THEIR VARIOUS STAGES

was the subject for discussion, which was opened by Dr. LEWIS A. SAYRE, of New York. Dr. Sayre restricted his observations to the joint diseases generally termed scrofulous, such as strumous disease of the ankle-joint, white swelling of the knee-joint, hip-joint disease, and Pott's disease of the spine. The position taken by the doctor was, that those diseases were essentially of traumatic origin. If they depended upon constitutional dyscrasia, how was it that many patients, after recovering from hip-joint disease, caries of the spine, etc., were ever afterwards sound and healthy? Moreover, the family history of many such cases could be traced back for many generations without finding any trace of scrofula or any other debilitating affection. The degenerative processes went on, in and about a slightly injured joint, and produced constitutional disturbance before the local manifestations attracted attention; therefore, by most, those local manifestations were regarded as the result of the constitutional dyscrasia. Even in strumous subjects, some local injury must occur before joint-disease developed, and in such subjects, especially, a very slight injury might be followed by very disastrous consequences. Scrofula, whatever it might be, exerted a most pernicious influence for evil after traumatism had done its work. The great and essential factors in the treatment of joint-diseases were extension and counter-extension, rest to the parts, tonics, friction and elastic compression, aspiration, free incision, excision.

Dr. BARTON, of Dublin, who had seen a large number of cases of *morbus coxarius* in the children's ward in his hospital, was convinced that, on the whole, Dr. Sayre's theory was correct—that the disease arose from some injury, and took its tone afterwards from the particular diathesis from which the patient was suffering.

Dr. J. T. HODGEN, of St. Louis, Mo., thought that both those who accepted the theory of traumatism, and those who accepted the theory that joint-diseases occurred only in strumous subjects, would accept the proposition that if this peculiar condition of system was not present, rendering the person liable to such diseases, no amount of force would develop them; but when it did exist, a very trifling injury might cause *morbus coxarius*, or other joint disease.

Dr. E. H. BENNETT, of Dublin, thought that the opinions of surgeons were very much with Dr. Sayre, especially with reference to the traumatic origin of joint disease as contrasted with its strumous origin.

Mr. OWEN, of London, believed that Dr. Sayre went too far in saying that each case required an exciting cause. Dr. Sayre had also said that he was disinclined to believe that those cases were of strumous origin because so many of them recovered completely; but surely, if a man having strumous disease

of the testicles could recover when they were removed, strumous disease of the joint might be just as curable.

Dr. WHEELER, of Dublin, did not agree with Dr. Sayre regarding the effect of motion in the treatment of joint disease.

Mr. WM. ADAMS, of London, agreed with Dr. Hodgen, and thought there was no very wide difference between Dr. Sayre and Dr. Gross on the subject of scrofula. He himself had been in favor of the traumatic origin of *morbus coxarius*, but he had also felt that it must be grafted on the constitution. He had largely adopted the extension principle. The treatment in that country seemed to lead to immobility, fixation, and ankylosis; but American surgeons allowed that motion which prevented ankylosis, and he thought that surgeons in Great Britain had a good deal to learn in that respect.

FRIDAY, AUGUST 8TH.

WILLIAM MACCORMAC, F.R.C.S., Vice-President, in the Chair.

ON THE CAUSE OF EVERSION OF THE LIMB AFTER FRACTURE OF THE NECK OF THE FEMUR.

Mr. EDMUND OWEN, F.R.C.S., of London, read a paper on the above subject, and illustrated his theory by means of diagrams. Sir Astley Cooper had attributed the eversion to the superior strength of the muscles of external rotation; and his views, which had afforded an excellent working hypothesis, had been generally adopted by subsequent writers. Mr. Owen, however, asserted that the thick mass of muscles of internal rotation were more powerful than the muscles of external rotation, though the latter were much more numerous. That important fact he had ascertained by testing the relative power of the two groups of muscles by means of a specially arranged spring-balance and indicator. His theory had the following factors: The posterior surface of the thigh of a man, lying supine on a flat surface, hardly touched that surface, the weight being transmitted partly by the pelvis, partly by the calf. The centre of gravity of the limb was well to the outer side of a straight line connecting the middle of the acetabulum and the heel. In search for stable equilibrium, the sound limb rolled outwards until further eversion was checked by the front of the capsular ligament rendered tense. In that position the limb was found in sleep, after paralysis, and in death. Division of the front of the capsule was followed by still further eversion, and the neck of the femur being divided inside the capsule, the limb rolled over on to its outer side. Similarly, when the neck of the living femur was broken the limb tumbled into the position of eversion, and muscular action had nothing to do with its position. The administration of chloroform was never followed by a righting of the limb. Extreme violence might leave the limb in a position of inversion after the fracture had been produced; but when the fragments were unlocked eversion at once declared itself and persisted. When the femur was fractured below the level of the lesser trochanter, eversion was still a most characteristic feature of the lesion.

Mr. COOPER POSTER, of London, concurred in Mr. Owen's theory, and the CHAIRMAN remarked that Mr. Owen had proved his case by observation and by experiment.

ON THE IMMEDIATE CURE OF HERNIA BY A NEW INSTRUMENT.

W. D. SPANTON, Esq., M.R.C.S., of Henley, read a paper on the above subject, in which, after alluding

to the great frequency of hernia and the comparatively small proportion in which any attempt was made to cure the affection, he referred to the methods hitherto practised, under four heads: 1. Contraction of the skin and sac by excision, cautery, or ligature; 2. Closure of the sac by adhesive inflammation; 3. Plugging the inguinal canal; 4. Bringing the walls of the canal together, which was first alluded to by Sir W. Lawrence, and brought into practical notice by Mr. John Wood, and was commonly known as Wood's operation. The great object being, according to Wood, to establish "complete union along the whole length of the canal." Mr. Spanton had devised an instrument by which that result might be obtained with greater certainty and safety than by any of the methods that had hitherto been employed. The instrument was of the shape of an ordinary corkscrew, and was introduced from above downward in such a way as to bring together the outer and inner pillars of the inguinal canal at three or four different points, and at the same time to secure the invaginated sac or fascia, which was separated subcutaneously in Wood's method, in the inguinal canal for a sufficient length of time to ensure complete occlusion of the hernial opening. The author related fourteen cases in which the operation had been performed, and, in all but one, the result had been quite satisfactory. In not a single instance had any dangerous symptoms resulted. The operation might not in all cases succeed perfectly, but it was a satisfaction to know that it was almost impossible to incur the odium of having, by it, left the patient so that his last state was worse than the first. He had observed in most cases a temporary swelling of the scrotum, sometimes to a considerable extent, but no ultimate inconvenience had resulted from the temporary pressure on the spermatic cord. If, at any time, injury was feared, the instrument could be easily withdrawn, the surgeon being content with what had been accomplished.

MR. ALCOCK, of Burslem, thought that Mr. Spanton's operation was incomparably easier than Mr. Wood's. He had performed the operation on a young woman on Thursday, and on Sunday there were no abnormal symptoms, and consolidation was gradually taking place.

ANALYSIS OF ONE HUNDRED CONSECUTIVE CASES OF OPERATION FOR STONE IN THE BLADDER.

W. F. TEEVAN, B.A., F.R.C.S., of London, reported a series of one hundred consecutive cases of operation for stone in the bladder, of which three were females, twenty-two were boys, and seventy-five were adult males varying from seventeen to seventy-seven years of age, the majority being between sixty and seventy years old. When he began to operate for stone in the bladder in February, 1863, he had two distinct objects in view: 1. He proposed to crush wherever practicable, in order to ascertain what were the limits within which it might be advantageously employed; and 2. To cut out a stone rather than extract it by the so-called method of dilatation after the primary incision had been made.

Of the twenty-two boys, the youngest was eighteen months old, the eldest fourteen years. All were operated on by lateral lithotomy. All recovered, and only three were troubled with incontinence of urine after the operation.

Of the seventy-five men operated on, fifty-five were relegated to lithotomy. The fifty-five cases occurred in fifty different men. In one case lithotrity was attempted but not persevered with, the man being relegated to lithotomy. In one case lithotrity was sup-

plemented by median lithotomy. The patient, aged 68, died from exhaustion due to cystitis. In one case cystotomy was performed with success, one year after lithotrity, for the cure of local irritation. Most of the cases were complicated by cystitis, enlarged prostate, stricture of the urethra, atony of the bladder, or by renal disease. Six patients died in his hands; three from the operation, three from other causes. Five patients were troubled with local irritation after the removal of the calculi. All the rest were cured. Lateral lithotomy was performed on thirty-four patients; twenty-two were the boys who all recovered and six died. Medio-lateral lithotomy was performed on two gentlemen. One died and one recovered. The medio-bilateral operation was performed on one patient, who died from suppression of urine. In two cases lithotrity, at one sitting followed immediately by external urethrotomy, was performed, both patients making good recoveries.

He would at all times prefer to cut out a stone rather than to tear it out. He did not believe that dilatation could be effected. As regarded hemorrhage, although there might be a great gush of blood at first, it would cease immediately, and he would not use any tube.

A NEW METHOD OF USING ICE.

DR. EDWYN ANDREW, of Shrewsbury, pointed out the advantages in certain surgical and medical cases of employing medicated ice. He thought the cold was rendered more effective by being combined with the active principles of drugs, and by freezing various medical solutions. In that manner ice might be rendered highly antiseptic, caustic, or styptic. In medical cases, especially of the throat, stomach, and hemorrhages from internal organs, ice might be thus pleasantly used to relieve symptoms and at the same time convey medicine as food to the stomach when the latter would resist them in any other way.

Correspondence.

LITHOLAPAXY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Will you allow me to correct an erroneous statement contained in one of your recent editorial articles upon the new lithotrity (Vol. 16, Nos. 7-8)? It relates to the lithotrite devised by me. This particular instrument is not indispensable for the performance of litholapaxy, since almost any lithotrite can be made to crush the stone—the novel and essential characteristic of the new method being the complete evacuation of the calculus by a long sitting and a large catheter. But, although the error referred to is unimportant, it should, I think, be corrected in deference to surgeons who use my non-impacting instrument.

The writer says, referring to the lock of this lithotrite, "the liability to break is a serious objection." . . . "Thompson's catch cannot be broken in this manner." Now, this is a mistake. My instrument, although employed by myself and others upon stones both large and hard, has never been, as your writer states, "broken." Nor do the parts he alludes to (the old screw-blocks of Charrière and their boxes) differ in strength from those of all other lithotrites,

inasmuch as they are identical in all of them. If one breaks, others must be liable to the same accident.

This writer has misapprehended a trivial occurrence, incidentally mentioned many months ago, in connection with the then novel method. This was what happened: Tiemann & Co. borrowed from me, for examination, a lithotrite just arrived, one of the first of my instruments made in Paris, and lent it for use. The French workman, to whom the lock was new, had miscalculated the width, in this combination, of the Charrière screw-blocks; so that when the instrument was locked and screwed up, these blocks had little or no bearing. They were at once lifted out of their boxes, just as they are purposely lifted out by the thumb and finger when they need cleaning. That was the whole of it. The skilful French maker, annoyed at the carelessness of his workman, made the lithotrite perfect in a few hours. And the surgeon, in whose hands the defective adjustment revealed itself, ordered one of my lithotrites from Weiss.

The error here corrected does not impair the general excellence of the other criticism, it being quite possible that the writer should be a skilful surgeon without being perfectly familiar with the locks of lithotrites; just as a skilful navigator may not have investigated the construction of the chronometer he uses.

Several of the critical remarks of your able editorial writer are well founded. He rightly says that the evacuating process, though not more efficient, is drier and neater if all the water is kept inside the aspirator and all the air outside of it; which implies that there should be good joints and no leakage, with stopcocks at all the orifices, one of them being at the highest point to let air out easily. I would add, however, that it is important not to lose sight of convenience in other respects.

The progress of the new lithotripsy was most liberally encouraged, at an early period, by New York surgeons. The attention now directed to some of the minor details connected with the instruments is rapidly contributing to their perfection.

Almost the only objection I have known made to the new method, either here or abroad, has been directed to the size of the instruments I generally use, which at first impressed persons accustomed to the use of Clover's aspirator and the English lithotrite as "clumsy" or "unwieldy." Large-sized catheters are absolutely indispensable, and are now so recognized. With regard to the size of the lithotrite, it is to a certain extent a matter of taste. My own instrument, with a wrist-lock, ball-handle, and non-impacting blades, is not necessarily larger than others. It can be had from Tiemann & Co. of any size the operator may prefer. I think, however, that large and hard stones will be found to require a more powerful instrument than those hitherto in use. In fact, it is very possible that a calculus should break a lithotrite. This accident happened from time to time in the practice of the old lithotripsy, and we are now dealing with larger and harder stones. That is one reason for avoiding a slender construction, especially of the blades. But my chief reason for using a large lithotrite is the convenient command it gives of the stone. Having learned how easy, as well as safe, with proper care and skill, is the introduction of large instruments, I prefer to use a powerful lithotrite, to crush even a moderate-sized calculus, provided the blades are so constructed as not to become impacted. With a small stone or fragment, the choice of a lithotrite is wholly unimportant; while a bladder or urethra, if exceptional in any way, may require an exceptional

instrument. But I do not see why some operators still enjoin the use, in all cases, of the smallest or lightest lithotrite that can possibly be made to crush the calculus.

HENRY J. BIGELOW.

BOSTON, MASS.

JABORANDI IN A SEVERE CASE OF PUERPERAL ALBUMINURIA WITH CONVULSIONS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I was summoned hastily August 8th, at 12 M., to Mrs. H—, nineteen years of age, primipara, whom I found in bed, dressed, lying on her back, and breathing heavily. From her mother I obtained the following history: The patient, Mrs. H—, was her son's wife, who had come from a neighboring town to be delivered. She had complained for the previous fortnight of nausea and vertigo, with dimness of vision and occasional very severe pains in head, and even her best days were rendered unbearable by a general feeling of malaise—listless and lifeless—yet she got up mornings and was about the house, passed but little urine, but that this morning, August 8th, while sitting by the window she was suddenly, without warning or noise, seized with a fit, fell to the floor, and was carried to the bed unconscious, where I saw her. She was at about the middle of the eighth month of pregnancy, she thought. She was unable to speak or swallow, and could not be roused to consciousness; her face, feet, and entire legs were œdematous, and pitted deeply on pressure; the œdema was very marked, the whole areolar tissue seemed infiltrated; the cervix I found was not dilated, but mostly effaced; passed catheter, but could obtain no urine; the skirts were wet with the urine, which had passed involuntarily in the first seizure; the bowels had moved in like manner; the convulsions followed each other at short intervals, and they were terrific to behold. She was a stout muscular blonde, and every muscle was engaged, the bloody, frothy mucus issuing from the mouth. During the intervals there was a heavy stertorous sleep, but no return to consciousness. The catheter was passed repeatedly, both before and after the fits, but could find no urine.

I gave by rectum 20 grs. hyd. chlor. and half drachm of fl. ex. jaborandi; applied ice to head; in half an hour gave by rectum 20 grs. chloral and 40 grs. brom. pot.; no effect on fits, they were severe and of epileptiform character. After an hour gave by hypodermic syringe 15 min. fl. ex. jaborandi; in half an hour repeated the dose, and in half an hour had profuse salivation and excessive diaphoresis. The convulsions were not altered; they seemed to be general and longer; respiration was labored, and dyspnoea distressing; there were numerous and loud bronchial and tracheal râles, but no interruption or cessation of fits; the salivation and sweating steadily going on. I then gave by inhalation sul. ether. I had seen before that the uterus was contracting, and could be easily felt through the abdominal walls; the ether controlled the attacks, but, owing to the great difficulty of respiration and bronchial obstruction, I dare not push it. On making examination found the os dilated and thin, membranes ruptured, the head presenting. When I applied the forceps, and delivered without difficulty a dead child (male), the placenta soon followed, the uterus contracted fairly. She had, up to the birth of the child, fifteen convulsions, but none after it; but now there was profound coma, pulse very feeble, respiration

noisy and short, dyspnoea distressing. She died four hours after, unconscious, as she had been from the first convulsion. The case is, I think, remarkable in some respects.

First.—Unconsciousness from the first, and striking resemblance of the fits to epilepsy. She had never been epileptic.

Second.—The general character of the convulsions.

Third.—The absence of urine, the catheter being passed both before and after convulsions. There was ischuria after the first attack.

Fourth.—In a case of the severity and gravity of the above it would be too much to expect of any one drug, and in so short a time, to eliminate enough urea from the system to materially affect the fits, and I would not condemn hastily; it is a most remarkable agent, a powerful eliminative and febrifuge, and will with certainty produce its specific effects; in this case the temperature was lowered one degree; it also brought on, I think, contraction of the uterus. It had no effect on the convulsions, or on the kidneys. But I would not use it again because, 1st, from its weakening effect on the heart and pulse, venesection is contraindicated; 2d, from the great increase of bronchial secretion that it pours out, anesthetics are contraindicated, for it will weaken the heart and obstruct respiration if given in sufficient doses to eliminate urea, and I should not exchange the old-fashioned venesection and anæsthetic, both of which its use seems to contraindicate. It did, at least, in the above case.

WILLIAMSTOWN, MASS.

“NEGATIVE PRESSURE.”

TO THE EDITOR OF THE MEDICAL RECORD.]

DEAR SIR:—There is a certain expression which has come into use in connection with the physics of respiration and circulation, to which I desire to call attention. It is the, according to Dr. G. M. Garland (see introduction to his work on “Pneumono-dynamics”), “scientific” expression *negative pressure*.

The idea of *negative force* is absurd. Force is essentially positive. The term referred to is a very bad substitute for the popular “suction force.” As every one knows, the active agent in “suction” is the pressure of the atmosphere outside of a more or less complete vacuum. To speak of *negative pressure* instead of *atmospheric pressure* is exactly equivalent to speaking of *the rising of the sun* when we mean *the rotation of the earth*. In common parlance either may be innocent enough; but anybody knows that in order to get a correct conception of astronomical facts we must discard the popular conception, and that it prevents confusion to discard also the popular expression.

In order to get any clear idea of the working of physical or any other laws, we must get a distinct conception of what, to use a tautological expression, the *positive forces* are at work in producing a given effect are, and how they do their work. In order to do this, our language should express *exactly* the truth. To use a technical phrase which is based on a false idea—which involves a confusion between cause and effect—can only lead to mistiness and error. To call such a phrase “scientific” is a singularly flagrant abuse of terms.

Respectfully yours,

R. VAN SANTVOORD, M.D.

66 WEST ELEVENTH STREET,

RECTAL HEMORRHAGE IN INFANCY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Early in the morning of the 20th of August I was called to deliver a woman of her second child—there having been an interval of ten years since her last confinement. The mother was a well-nourished, vigorous woman, without any visible taint of previous constitutional disease.

The labor being rapid and comparatively easy, she was, about an hour after my arrival, delivered of a female infant weighing about eight pounds, and of perfect formation in every particular.

Everything went on well until the child was three days old, when the nurse directed my attention to the unnatural quality of the infant's stools.

I found that there had been a copious discharge of dark, tarry matter of such a character as I never before witnessed.

Supposing from indications then existing, that a moderate laxative was needed, I directed that half a teaspoonful of castor oil be given. Within two hours from the time I left the house another call came, requesting me to proceed immediately to see the infant. I then found a condition of things of which I have never read or heard. There were frequent and large evacuations from the rectum, *now* of strawberry-colored liquid, and about the consistence of thin porridge. The little patient was rapidly becoming anæmic and very feeble.

I now concluded that there was rupture of a blood-vessel somewhere along the intestinal tract, and knew that in order to be able to arrest it, the point at which the opening existed must be found. Before deliberating on that question, however, I administered brandy freely in small quantities, wrapped the baby up in a warm blanket, and gave an injection of a strong solution of alum; but it no sooner entered the bowel than it was rejected, closely followed, for the first time, by as much as three ounces of pure blood. I substituted a solution of the pernitrate of iron for the alum, but with no better effect; and while making every effort to preserve the life, the child succumbed from the large and speedy flow of blood.

Being somewhat chagrined at my helplessness in the case when every one looked to me, as the physician, for aid, and being embarrassed as to the cause, I pressed for a post-mortem, and was gratified by the consent of the parents.

Early in the morning following death, in company with Mr. Thos. F. Breene, a medical student, I made an autopsy.

The body revealed nothing unusual till we reached the rectum. Beginning at the anus I traced up the blood-stained mucous lining of the bowel for about three inches, and here the blood-stain abruptly ceased. Carefully scraping the glazed covering from the interior of the bowel, in search of an orifice that might account for the flooding, I was shortly rewarded for my trouble by finding an erosion and opening in one of the larger intestinal veins. From this a small quantity of a sanguineous discharge escaped on the least pressure from above. The opening was of sufficient size to readily admit the passage of a bristle.

To determine whether it would be possible during life to remedy this condition, I returned the bowel, and found that had I correctly understood the seat of hemorrhage I might easily have checked it by passing the little finger up the rectum and pressing on its tip, or by packing with cotton batting and some styptic.

The interesting features in the case, which I believe

will justify me in offering it for publication, are, first, the absence of any author's description of this accident, either medical or surgical—a fact proving its extreme rarity; and secondly, the fact, as the autopsy revealed, of the nearness to the anus of the opening in the gut.

It is to be hoped that should a case of the kind described above ever come under the care of a practitioner who has seen or read these desultory remarks, it may be treated with intelligence and positive success.

Yours respectfully,

T. H. MANLEY, M.D.

LAWRENCE, MASS.

POISONING BY A BEE-STING.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—On the 27th of August I was called to see Mrs. G—, æt. 70, a well-preserved old lady who generally enjoys robust health. I found her vomiting violently, and was informed that active emesis had been going on for some three hours with hardly an intermission; and that a short time before she grew sick she had been stung twice on the wrists by “an animated torrid zone,” as Ralph Waldo Emerson terms an humble-bee. Pulse and temperature normal; skin bathed in perspiration.

I ordered a large mustard draft applied to the epigastrium; gave her a powder of bismuth and ox. cerium, and cracked ice *ad libitum*. Not having my hypodermic syringe with me, I went to my office for it; was detained half an hour. Upon my return, I found my patient had rejected everything taken, and was almost in a collapsed state, with feeble circulation, irregular action of the heart, and almost complete absence of pulse at the wrist. Temperature, 96° F. I gave her brandy and spt. ammon. aro. *per os*, and morphia sulph. hypodermically, had her cold extremities rubbed, hot applications to her limbs, and extra blankets put on her. The ammonia and brandy was promptly rejected, but, much to my relief, the morphia and the external agents used soon began to have a beneficial effect, and in about an hour reaction came on, and she was out of immediate danger. I gave her nothing but small bits of ice, which she was only able to retain by a great effort. I repeated the hypodermic injection at bedtime. She rested well during the night, and the next morning was able to take teaspoonful doses of ice-cold milk and lime-water; and though so much prostrated as to be obliged to keep her bed several days, has made a good recovery.

In that invaluable repository of medical knowledge, “Ziemssen's Cyclopædia,” Vol. III., Bollinger gives an admirable description of infection by bee-stings, which I quote *in extenso*: “Wounds of this character have in rare instances been known to be followed by symptoms of blood-poisoning, and now and then by a fatal result. Such dangerous stings are mostly inflicted in certain special parts of the body, as, for instance, near the eyes, ears, and lips, and occur in feeble women or in old persons.

“The constitutional symptoms are usually nausea, faintness, great weakness, vomiting, præcordial distress, difficulty in breathing, also coldness of the extremities, and frequently petechie on the body, or the general eruption of a pale-reddish exanthema, either resembling that of measles, or in the form of wheals, with intense itching. Less frequently an excessive thirst is experienced, and a hoarseness increasing to an absolute aphonia.

“In place of the slight redness and swelling in the

vicinity of the sting, there appear at times an extensive tumefaction and lividity, which may involve a large portion of the affected limb, or even the entire body. These phenomena last for several hours, disappearing in favorable cases speedily, or within a few days. In many instances death ensues within a quarter of an hour, or even a few moments.

“It is probable that in such cases the virus has been ejected from the sting directly into a blood-vessel.”

None of the above phenomena were present in Mrs. G.'s case, except the constitutional symptoms, which were exactly as Bollinger describes them, and considerable tumefaction of the wrists in the region of the stings.

Respectfully yours,

WM. E. BRANDT, M.D.,

Late A. A. Surg., U.S.A.

HANOVER, INDIANA.

RETAINED PLACENTA OF NEARLY FIVE MONTHS' STANDING.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I called to see Mrs. V. D—, June 12th, at which time she gave me the following history:

The last regular menstruation which she experienced terminated November 8, 1878. She was married November 12th of the same month; she did not menstruate again—or see anything—as she expressed it, until early in February, 1879, at which time she was taken suddenly with pain and excessive flowing.

The family physician was called, and he, supposing that the patient was threatened with miscarriage, prescribed for her and advised rest in the recumbent posture. No vaginal examination was made at that time. The patient was soon around again, and for two months following she was about the same as usual at her “periods.”

For the next two or three months, however, she has suffered from metrorrhagia, which had continued up to the time I saw her. She was very much reduced in strength; never had fever or chills, some pain in the back, appetite very good, but feeling weak. On making a vaginal examination the uterus was found to be somewhat enlarged and retroverted, no tenderness on pressure over the fundus. I corrected the displacement, and knowing that the malposition of the organ might give rise to congestion, enlargement, and hemorrhage, I was at first inclined to consider that as the cause, yet the previous history led me to suspect some foreign body within the cavity of the uterus. I therefore concluded to use ergot, and if any subsequent hemorrhage ensued, to dilate the cervical canal and make an examination into the interior of the womb. Prescribed a half drachm of the fluid extract of ergot every four hours.

No bleeding occurred for a week, and the patient was feeling stronger, and without my knowledge or consent (which I should not have given), she took a long ride to a neighboring town, and while on the way back she felt some pain in the pelvic region, and found that she was flowing again. The pain was quite severe, and the hemorrhage continued until about 7 o'clock P.M., when an oblong body, about the size of a two months' fetus, was expelled from the uterus. I was hastily summoned with the not very comforting assurance that Mrs. V. D— was dying, which I found to be an exaggeration on arriving at the house, as my patient was very cheerful, not having in any respect the appearance of being “in

articulo mortis." On examination, I found the os dilated, but nothing within the fundus. The following day the uterus was firmly contracted and the os closed. There was no subsequent hemorrhage and no offensive discharge more than at menstruation. She gradually improved, and is now quite in her usual health. About the 1st of July she again menstruated, it being the time for the "monthly periods" as compared with the previous dates. On making a careful examination at my office a few hours after, of the substance discharged, I found it to be a placenta with its edges agglutinated, having assumed the shape of the cavity of the uterus, showing that it had remained within that organ some time after separation had taken place from its surface. The fact that the after-birth remained in the uterus for nearly five months after the loss of the fetus, without decomposition, and with no serious results other than the effect which the metrorrhagia would naturally have upon the system, leads me to report the case; although the prompt action and undoubted efficacy of the ergot in producing uterine contraction, and consequent expulsion of its contents, are also of considerable interest.

Very respectfully,

G. H. LATHROP, M.D.

WURTSBORO', N. Y.

New Instruments.

A NEW APPARATUS FOR FRACTURED CLAVICLE.

By THOMAS E. SATTERTHWAITE, M.D.,

NEW YORK.

THE method here described has been in use for nearly a year, and has given entire satisfaction in the two instances where it was applied. The three prominent indications in this accident are, obviously, to correct the downward, forward, and inward displacement of the outer fragment of the clavicle. Accordingly, the shoulder is to be carried upward, backward, and outward. The first and second of these manœuvres is successfully accomplished by the adhesive plaster method, but the third is usually neglected, because it is generally impracticable, unless the ordinary axillary pad is used, an appliance that cannot be borne without great pain and annoyance. The merits of this present plan are chiefly due to the *elastic force* which is brought into play. As is well known, this accomplishes more in overcoming muscular resistance, and with less convenience than any other force similar in amount.

The essentials of the appliance are, first, a soft rubber bag, and second, moderately stout elastic bandages in place of the ordinary adhesive ones that are commonly used, as in the method given to the public by Dr. L. A. Sayre (*American Practitioner*, July, 1871).

The bag is horse-shoe in shape, and forms a fulcrum when placed in the axilla, as in the ordinary V-shaped pad of Fox's apparatus. The humerus is now the long arm of the lever, and when brought close to the side of the body, withdraws the outer fragment of the clavicle from its false position and restores the bone to its former length. The elastic bandages which are next applied maintain the position when once secured, and keep the fractured ends in more accurate apposition. The bag (Fig. 1, *a*) should be moderately filled with water (about three-quarters full); it

is then pressed snugly into the axilla and held there by a narrow rubber band, which passes around the neck. (Figs. 1 and 2.)

Water is better than air because it is less compressible and more apt to remain in the proper position. Water also adapts itself admirably to the inequalities of the surface, and makes continuous pressure over a broad area, so that it is hardly likely to cause ulceration, even when very firmly compressed. The required quantity of water may easily be injected through the tube (Fig. 1, *b*), which can be tied in a knot so that not a drop will escape. The elastic band about the neck keeps the pad in place, whatever position the head or body may assume. Sometimes rubber bands from the side of the bag may be passed around the chest as an additional means of keeping it in place.

The other parts of the apparatus are simply two strips of gum bandage (Martin's), reinforced at intervals by transverse strips of cotton cloth (Fig. 1, *d*), through which round holes are pierced for the collar button (Fig. 1, *e*), which is used to hold the bands in position. They are adjusted as follows:

A loop of the bandage is first passed round the lower part of the arm (Fig. 3, *a*) and securely fastened behind with two collar buttons; it is then passed around the waist, its course being spirally

FIG. 1.

FIG. 2.

downward (see Figs. 2 and 3); returning, the point of the elbow is caught in the soft rubber which forms a partial sling for it (Fig. 3, *b*); then it is carried over

the shoulder of the opposite side; thence returning (Fig. 2), and passing again over the point of the elbow (Fig. 2, *a*) it completes the sling. Two collar-buttons finally secure it on the posterior surface of the arm (Fig. 3, *a*). The hand of the affected side is attached to the band in a way that is comparatively easy and comfortable, by the narrower elastic strip (Fig. 1, *c*), with figure-of-eight turns (Fig. 2). In the

FIG. 3.

two instances wherethis plan was tried, the apparatus was worn with very slight inconvenience, much less than in any previous cases the writer has seen. The resulting deformity was very slight, and consolidation was accomplished in about four weeks. No excoriation takes place if the bandages are properly applied. The apparatus is *clean* and *light*; once in proper position it should not need any readjustment.

50 E. 31st St.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 13th to 20th, 1879.

ADAIR, GEO. W., Lieut. and Asst. Surgeon. Assigned to duty as Post Surgeon, Fort Mackinac, Michigan. S. O. 161, Dept. East, Sept. 13, 1879.

MIDDLETON, P., Capt. and Asst. Surgeon. Relieved from duty in the Department of the East, to take effect Oct. 1, 1879, and to report to the Commanding General Department of Texas for assignment to duty. S. O. 215, C. S., A. G. O., Sept. 17, 1879.

THE AMERICAN ACADEMY OF MEDICINE.—The Third Annual Meeting of this Society was held at the rooms of the New York Academy of Medicine, on the 16th and 17th of Sept., 1879.

The following officers were elected for the ensuing year: *For President*, F. D. Lente, M.D., of New York. *For Secretary*, R. J. Dunglison, M.D., of Philadelphia. The next meeting will be held in the city of Providence, beginning on the third Tuesday in September, 1880.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT.—Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending September 20, 1879.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Sept. 13, 1879.	0	17	23	1	19	15	0	0
Sept. 20, 1879.	1	8	41	1	38	13	0	0

THE YELLOW FEVER.—The number of new cases of yellow fever developed in the city of Memphis from September 16th to September 23d inclusive was 85, and the number of deaths that occurred was 33. The total number of new cases for this year to September 24th is 1,267, and the total number of deaths 409.

September 20th.—The indications seem to be that the pestilence is losing its power, yet the health authorities have officially advised that refugees continue to remain away from the city.

It is seventy-two days since the first case was developed this year, and the fact that the disease still continues in existence disposes of the theory that yellow fever will, without the influence of frost or other destroying agency, expend its force within sixty days.

DR. CHARLES ABBOTT, of Winterport, Waldo Co., Maine, died August 19th, at the age of 55 years. He graduated at the Medical Department of the University of New York in 1849, and settled in his native town. He served as surgeon of the Twelfth-sixth Regiment of Maine Volunteers, and was a prominent physician and surgeon in Eastern Maine. His father, Dr. Edmund Abbott, settled in the same town in 1804 and practised there fifty years. The son of Dr. C. Abbott, Edmund Abbott, M.D., was a graduate of New York University, class of 1879, and takes his father's place.

A NEW QUARANTINE STATION ON THE DELAWARE RIVER.—The following communication was read at the last meeting of the Philadelphia Board of Health on Monday, September 8th, viz.:

NATIONAL BOARD OF HEALTH, }
WASHINGTON, D. C., Sept. 6, 1879. }

To the President of the Board of Health, Philadelphia, Pennsylvania:

SIR:—I have the honor to transmit herewith a copy of Bulletin No. 10, containing a copy of the rules and regulations drawn up by this Board, and approved by the President, August 22d, relative to the establishment at the mouth of the Delaware River, in the vicinity of the Breakwater, a quarantine station of observation, for the purpose of inspecting vessels entering the Delaware River. I have also the honor to inform you, that the President has directed the detail of Medical Inspector J. C. Spear, U. S. Navy, to enforce these regulations, and that he will be stationed at the Breakwater for that purpose. Upon reporting to this office for orders, he will be instructed to consult with you prior to taking station at the Breakwater. Yours, etc., J. S. BILLINGS,
V. P. National Board of Health.

The discussion which followed the receipt of this communication was lengthy. The Board were unanimous in believing that if the rules thus established were carried out the trade of the port of Philadelphia would be ruined by the unnecessary detention to vessels and passengers coming from abroad, as all vessels would be detained at the Breakwater until it

sued the national officers to make the inspection. At the close of the meeting a resolution was adopted requesting the National Board of Health to suspend action in the matter until notified of the action of the Board of Health of Philadelphia.

The Philadelphia *Public Ledger* of Sept. 9th, in an editorial headed "Too Much Quarantine," deploras the action of the National Board of Health as an "error in its beginning and conclusion," and points out that the choice of the Breakwater as a site for the new quarantine is most unfortunate, it being a most impracticable place for the medical inspection of incoming vessels, the quarantine station at the Lazaretto, already existing, enabling the sanitary inspection of vessels to be made with the least possible delay to commerce.

The boarding station at the old quarantine is within easy reach of the channel, so that vessels from infected parts can be boarded without the need of their stopping at all, whereas, at the Delaware Breakwater all vessels would have to be brought to anchor, and vessels arriving at dusk would have to lay over until the next day.

SOCIAL SCIENCE ASSOCIATION.—This association held its annual meeting at Saratoga on Sept. 11th, 12th, and 13th. A number of papers of interest to the medical profession were read at its sessions, sanitary matters especially being the subject of discussion.

Mr. Angell, of Boston, read a paper upon "Adulterations in Food and Drink." A similar contribution was made by him a year ago, and was noticed by this journal. This year, in the discussion that followed his paper, a number of his statements in regard to adulterations were contradicted.

Pres. F. P. Barnard read a long and very exhaustive article on "International Coinage, Weights, and Measures." He showed the lack of uniformity in our present system, and urged with much enthusiasm the adoption of the metric.

Col. Geo. E. Waring, Jr., of Newport, read a paper on the "Sewerage of Villages and Cities."

"The Sanitary Condition of Tenement-Houses" was the theme of Charles P. Russell, M.D., of this city; and this was followed by a paper on "The Tenement-House, and the Latest Improvements Therein," by Charles F. Wingate. A discussion upon the value of uniting sanitary and poor-law Boards followed, in which the success of such a system as at present existing in England and Massachusetts was shown.

Dr. White read a paper on "Yellow Fever," and Charles L. Brace, of New York, a long dissertation on "The Care of Poor Children."

QUACKERY IN NEW YORK.—At a meeting of the city aldermen, September 15th, the following resolution was introduced and referred to the Committee on Laws:

Resolved, That the Counsel to the Corporation be requested to report to the Board if there is any law of this State prohibiting persons not graduates of medical colleges from practising as surgeons and physicians in this city; if not, if it is legally in the power of the Common Council of this city to pass an ordinance to prohibit such persons from practising by imposing a penalty for violation of its provisions; and if such power exists in the local authorities, that he transmit to this Board the draft of such an ordinance, fixing the penalty at \$100 for every offence.

VISITORS FROM ABROAD.—Dr. Henry W. Acland, who is visiting this country, and who took a prominent part at the recent meeting of the American So-

cial Science Association, spent several days in New York last week. He attended a meeting of the Board of Health, and afterward went through several of the city institutions. Dr. Acland has long been prominent as a sanitarian, and has written many papers on sanitary subjects.

PRELIMINARY EDUCATION FOR MEDICAL STUDENTS.—This subject was discussed again by Dr. Lewis H. Stiner, at the fourth annual meeting of the American Academy of Medicine, recently held, and the same lamentable facts in regard to medical education were presented. Dr. Stiner asserts that the old-fashioned college curriculum furnishes the best preliminary training.

COLLECTING DOCTORS' BILLS.—The sorrows and the failures attending this interesting part of medical practice attracted the attention of the Northwestern Medical Association at its last meeting. To remedy the evil it proposes that on the face of the bills shall be printed: "Bills rendered monthly, or within thirty days after service." On one end is printed: "Ten per cent. discount will be allowed if payment is made within thirty days. Lawful interest will be charged after thirty days." On the other end is the name of the collector chosen by the Association.

THE NEW YORK ACADEMY OF MEDICINE.—The new library hall of the New York Academy of Medicine will be dedicated on the evening of October 2d, to which the profession of this city and of Brooklyn are invited. Short addresses may be expected from Dr. Acland, Reg. Prof. of Oxford University, Mr. Callender of London, Prof. Gross of Philadelphia, Dr. J. S. Billings of Washington, and other distinguished members of the profession.

THE AMERICAN GYNECOLOGICAL SOCIETY.—At the Fourth Annual Meeting of this Society, held in the city of Baltimore, September 17, 18, and 19, 1879, the following officers were elected for the ensuing year: *For President*—Dr. J. Marion Sims, of New York. *For Vice-Presidents*—Dr. Robert Battey, of Rome, Ga., and Dr. W. T. Howard, of Baltimore, Md. *For Members of the Council*—Dr. W. Goodell, of Philadelphia; Dr. E. W. Jenks, of Chicago; Dr. A. D. Sinclair, of Boston; and Dr. A. J. C. Skene, of Brooklyn. *For Secretary*—Dr. James R. Chadwick, of Boston. *For Treasurer*—Dr. Paul F. Mundé, of New York. The next annual meeting will be held in the city of Cincinnati, beginning on the first Wednesday in September, 1880.

QUININE, SOLUTION OF IN STOMACH.—A weak tartaric acid lemonade taken after quinine is said to hasten solution and absorption, and relieves gastric irritability.

CLINICAL LECTURE ON DISEASES OF WOMEN.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

By T. GAILLARD THOMAS, M.D.

CASE I.—*Laceration of the Cervix, with Subinvolution and Retroflexion.*

GENTLEMEN:—Our first patient to-day is Mrs. Ellen C—, a native of Ireland, and thirty-seven years of age. She has been married thirteen years, and has had seven children and two miscarriages. Her last miscarriage occurred two years ago.

"How long have you been sick, Mrs. C—?"

"Two years."

"How old is your youngest child?"

"Three years."

"What have you complained of during the last two years?"

"A constant pain in the back."

"What else?"

"Pain in the left side." (The patient here placed her hand over the region of the left ovary.)

"Have you had pain anywhere else?"

"In the left groin."

"Is there anything else that has troubled you?"

"I lose too much blood at the time of my monthly sickness."

"Do you have the whites?"

"No."

"Is there any other trouble?"

"My appetite is very poor, and I suffer from headache."

"Are you able to attend to your work?"

"I am obliged to work, but cannot do it nearly as well as before."

You observe that in this case, gentlemen, we have all the ordinary symptoms of uterine disease, with the single exception (according to the patient's account) of leucorrhœa. Without her apparently being aware of the fact, however, this symptom is also present in quite a marked manner, as I discovered on making a vaginal examination; so that nothing is lacking to complete the evidence of the existence of such trouble.

Let me now briefly recapitulate the history of the case as it has been given to us. Three years ago this patient was a perfectly healthy woman; but two years since she had a miscarriage, and this was followed by (1) pain in the back, (2) pain in the left iliac fossa, (3) pain in the left groin, (4) menorrhagia, (5) headache and loss of appetite, (6) partial inability to attend to daily work, and finally I add leucorrhœa. I want you to remember in this connection what I told you in my last didactic lecture, that in every case there are a great many links in a chain, as it were, and would urge you as strongly as I can to always try to connect these in a philosophical manner, in order that you may learn to take as broad a view of uterine disease as possible. You must try to look at the symptoms as so many evidences of certain troubles in the system, and endeavor to found on the symptoms a logical opinion as to the general nature of the case in as full and perfect a

manner as you are able. The case now before us will serve as an excellent illustration of my meaning.

In the first place, when I made an examination of the patient, my finger came in contact not with an ordinary cervix, but with one whose torn lips were widely gaping, so that it passed at once up to the os internum. In addition, I found that the exposed surface was covered with a thick, tenacious mucus, because the Nabothian glands, unprotected, as they should be, by the cervical walls, were continually pouring forth a free discharge. Now some men, who take a very narrow view of uterine disease, are in the habit of seizing upon one of the links of which I have been speaking without regard to any of the others, and basing their diagnosis upon this alone. Such a diagnostician would be content with the examination as thus made, without troubling himself to go any further, and would declare the case to be simply one of laceration of the cervix.

But this was not all that I discovered by my examination. On practising conjoined manipulation, I found that the body of the uterus was not in its normal position, and ascertained that the organ was in a state of marked retroflexion. A second diagnostician of the superficial character to which I have alluded, might therefore pitch upon this displacement, and call the case merely one of retroflexion.

But still further, in making this conjoined manipulation, I discovered that the uterus was greatly enlarged, and exquisitely tender to the touch. Here, then, would be a grand opening for a third diagnostician, who would declare the case to be one of chronic metritis, and say that all the patient's suffering was due to the inflammatory trouble present.

But this is not all yet. As I continued my examination, I received the impression that the perineum had been completely ruptured through; but I afterwards ascertained that instead of this, it was still intact, although it was perfectly worthless. This was because it was altogether so weak and flaccid as to be quite incapable of supporting the anterior wall of the vagina, as it ought to do. It then occurred to me that something had gone wrong with the perineum as well as the cervix in labor.

Is there, then, chronic metritis here? Not at all. Either after the last miscarriage, or labor, (and more probably the latter,) the uterus did not return to its normal size, but was left in a condition of subinvolution, as it is called. If it occurred after the labor at full term, it was, no doubt, the cause of the more recent miscarriage. The state of the organ is one of hyperplasia, a hypertrophy of tissue requiring a larger supply of blood, and involving an alteration of the uterine nerves, which produces the tenderness of the organ that has been noted. In the same way the perineum did not undergo proper involution after the labor, but was left in the weak and flabby condition in which we now find it.

There are two very important points in the case which it is necessary that we should determine, and these are, *first*, What is really the matter with the patient? and, *second*, What can be done to cure her? One is just as important as the other; and if the true nature of the case is not understood, there is no hope of obtaining a cure, unless, indeed, (which is altogether improbable,) you should, by some lucky accident, hit upon the right method of treatment. I propose now to show you briefly what I believe to be the connection of the various links of symptoms to which your attention has been called in this case.

At the time of the patient's last labor at full term, the child's head ripped the cervix on each side, and,

the delivery over, the woman did not get well as she ought to have done, but had what the monthly nurses call "a bad getting up." This was because the lochial discharge (composed, as it was, of disintegrating uterine elements floating in a sanious fluid) acted as an irritant as it poured over and bathed the surfaces left raw by the process of parturition. How irritating this fluid is, is shown by the fact that nurses not infrequently suffer from erysipelas or angeioleucitis simply from having it temporarily in contact with their hands when there is any little abrasion of the skin present. On account of the irritation thus produced, involution was, no doubt, interfered with, and at the end of two months, when it should have already returned to its original size, the uterus was still very large and flabby. Neither did the perineum undergo involution as it should have done.

On my inquiring particularly of the patient if she did not have a bad "getting up" after the birth of her last child, she replied that she did not notice anything out of the way, and got up about the same time as usual in her other labors. But this statement does not in the least invalidate what I have just said. There are many well-authenticated peripartetic cases of typhoid fever on record, and sometimes actual perforation of the intestines has taken place without the patient's knowing that he was affected with the disease. So here there has, no doubt, been septicæmia present, but it has probably been of such a low grade that the patient was not aware that anything was wrong with her. This, then, is the first link in our chain.

Now when the patient got up after the labor, and went about her usual avocations, instead of having in her body a uterus of small size, and composed of new tissue, (as is the case after normal parturition) she had there a large and flabby one made up of old material. The consequence was, that on account of its great weight and atony it gradually fell back in the pelvis, and then the accumulation of fecal masses in the intestines pressed it still further and further down. You are aware that aneurisms are sometimes treated by flexing the limb on which they occur, in order to diminish the supply of blood to the part. So this flexion of the uterus no doubt interfered decidedly with the vascular condition of the organ, and it acted very much as ligating it with a loose string might; that is, it permitted a full supply of blood to reach the uterus by means of the arteries, but cut off, to a great extent, the return of the blood through the veins. The condition of the uterus thus occasioned is what has improperly been called metritis.

In this manner the organ is kept in a turgid condition all the time, and whenever the menstrual period comes around, the flow of blood is abnormally great. In this case the patient tells me she menstruates every two weeks, and at each period loses a large quantity of blood. This is because the uterus is so engorged that the venules and arterioles rupture very easily. Another symptom also accounted for by the constant hyperæmia of the uterus is the leucorrhœa, although this is in part due also to the abnormal condition of the cervix.

What, then, is really the matter with the patient? If you want to be a pathologist who, to use a not very elegant expression, "cannot see any further than his nose," you can take any one of the above conditions and make a diagnosis of it, such as "chronic metritis," laceration of the cervix, retroflexion, "endometritis," uterine catarrh, etc. Different observers might fix upon any one of these, and each would have a certain amount of truth in his opinion of the case; but all

such would be but poor gynæcologists and superficial pathologists. When in any case I am called upon for a written opinion, I am usually very careful not to base my diagnosis upon one point alone.

Having made this matter sufficiently plain to you, as I trust, I pass on now to the subject of treatment; and I do not hesitate to say most emphatically that the patient can be perfectly cured of all her troubles, provided she is able to avail herself of all the remedial measures which may be suggested for her benefit. In the first place, she should be put to bed and treated with gentle cathartics, in order to relieve the bowels. She should take an almost exclusively fluid diet, and her vagina should be thoroughly syringed with hot water perhaps as often as three times a day, and, at all events, every night and morning. This is on the same principle that you would keep an inflamed eye bathed with warm water, or would apply warm poultices to a paronychia. After a week of this treatment, the parts would be in a decidedly less irritable condition than at present, and the patient being placed on her side, with her arm thrown behind her, the medical attendant should place two fingers against the fundus and gradually press up the displaced organ into its proper position. This having been accomplished, an appropriate pessary should be introduced for the purpose of keeping it in place, and, if necessary, the patient might then be allowed to get up and attend to her usual duties. It is decidedly the *best* method, however, to keep her confined to bed, and especially if the physician is not a very experienced gynæcologist; because there is always a little risk in putting in a pessary in any case where the uterus has long remained out of its proper position. But the chances are that the instrument will be perfectly tolerated, and when the woman gets up to walk about, it will be impossible for the organ to fall back into its former malposition. You have now taken away the string that has so long constricted it, and, as a consequence, both the venous and arterial blood circulate through its vessels. At once the "endometritis" begins to get better, and in forty-eight hours after the pessary has been introduced, the patient will probably tell you that she feels more comfortable than she has for the last two or three years.

In two weeks more, the vagina in the meanwhile having been kept well syringed with hot water, the operation for laceration of the cervix, as described and carried out at our last clinic, should be performed; the sutures being allowed to remain in position for nine days. A focus of irritation will have been thus removed, and the leucorrhœa will afterwards be found to have almost, if not entirely, disappeared; the lining membrane of the cervix being no longer everted, and so exposed to the irritation of the air, coitus, etc.

Almost all the symptoms, therefore, will presently disappear, viz.: the backache, the leucorrhœa, and the pain in the left iliac fossa and groin, due to the tension on the round and broad ligaments. Only one will remain, the menorrhagia and too frequent menstruation. But it is the flexure of the uterus which has kept up the engorged condition from which this has resulted, and as time goes on this symptom will also be happily removed. Now you have really done very little, and yet the patient is getting well rapidly. By the end of three months she will probably think it quite unnecessary to continue treatment any longer, and she will have been cured for the reason that you have taken a rational and philosophical view of the case. This is no fancy sketch, I assure you, and I only hope that the points to which I have called your attention have been

impressed upon your minds with sufficient force and clearness, so that you will not fail to remember them when you come to meet such cases in your practice.

There is, however, something very discouraging in the practice of a clinic like this, because in reality almost nothing in the way of treatment can be properly carried out. It is ordinarily quite impossible for patients of the character we have here to remain in bed, and if we put in a pessary, the chances are that the woman will be standing on her feet for eighteen out of twenty-four hours afterward, and will come back the next week with the report that it has done her a great deal more harm than good. In the great majority of instances the only hope for a permanent cure is for the patient to go into a hospital; but, alas, this too is generally impracticable, for it is impossible for her to give up even for a short time the care of her house and family.

CASE II.—*Anteversion, Fungoid Degeneration of Uterine Mucous Membrane, and Sterility.*

Mrs. Alice C—, aged twenty-two years; has been married five years, and has never been pregnant.

"How long have you been sick?"

"I cannot fix on any definite time."

"Has it been a source of trouble that you have not borne any children?"

"Yes." It is principally to find out the cause of her sterility, if possible, that she has come here to-day.

"Do you suffer from any pain?"

"Only a little in the back."

"Are you regular in your monthly periods?"

"I lose too much blood then."

"How long do you stay in bed at such times?"

"I do not go to bed at all."

"How long does your sickness last?"

"About a week."

"Do you have the whites?"

"Not now; but I used to have them quite badly."

The chief thing in this case would seem, then, to be the sterility.

When I came to make a vaginal examination here, I found the cervix away back in the hollow of the sacrum, and the body of the uterus, consequently, lying forward. On account of the history of menorrhagia, I was led to apply the curette to the uterine mucous membrane, and I quickly withdrew a perfect specimen of the fungoid growths to which I have already several times called your attention. Their presence fully accounts for the too great loss of blood at the monthly periods, and this condition of the endometrium and the anteversion were all the pathological points that I noticed.

Now how can we account for the symptoms? *First*, the backache is to be attributed in part to the congestion incidental to the malposition of the uterus, and in part to the dragging on the ligaments, as well as the direct pressure of the uterus. *Second*, as to the sterility. In the antevverted position of the uterus, the posterior wall of the vagina acts as a valve which covers the os externum, and so forms a mechanical bar to impregnation. Then uterine catarrh, which results from congestion, such as is caused here by the displacement, is a frequent cause of sterility. As to the menorrhagia, it has already been seen to be due to the fungoid proliferation of the lining membrane of the uterus. Such growths not infrequently exist in women who have never borne children, and I have met with them in girls of only sixteen. They may occur, indeed, in any uterus that has been kept congested for some time.

The question now arises, can we cure this patient?

I think we can; but it will certainly take a considerable time to do it in. Chronic uterine catarrh, like that of other mucous tracts, is apt to be very obstinate. The first thing to be done is to put the uterus in proper position, for there is no other method of relieving the existing congestion. It should then be kept in place by means of an anteversion pessary, and vaginal injections should be constantly employed to keep the parts free from irritation. After the next menstrual period the endometrium should be carefully and thoroughly scraped with the curette, and all the fungoid growths removed. By these measures I should hope to remove both the menorrhagia and the leucorrhœa. There is one thing that I am a little doubtful about, and that is the point concerning which the patient is most anxious, viz., the sterility. This will undoubtedly be the last symptom to disappear, and we must not be too sanguine in reference to it.

CASE III.—*Carcinoma Uteri.*

Mrs. Ernestine H—, a native of Germany, and thirty-four years of age; she has been married eleven years and has had seven children, but no miscarriages. As the patient is entirely unable to speak English, I am obliged to avail myself of the services of Dr. Körner, who has kindly consented to act as interpreter. From him I learn that she has been complaining ever since the birth of her last child, which occurred two and a half years ago. The first symptom was a pain in the back, which afterward extended down the sides of the limbs. The most serious symptom, however, has been profuse hemorrhage, which made its appearance not long after the birth of the child referred to. Immediately after the woman got up there set in a very abundant leucorrhœa, and in one month more it was replaced by hemorrhage. This has continued to a greater or less extent ever since. The symptoms then are few in number, consisting of constant metrorrhagia for two and a half years, following a labor, pain in the back, etc., and marked depreciation of the general health, but they are very significant indeed.

I will now show you on the blackboard the result of the vaginal examination which I made in the case. The patient lying upon the back, I found the uterus in its normal position, but instead of the normal cervix there was a gaping cavity, such as I now roughly represent to you, with a sharp edge. As I pressed on its surface it seemed crisp to the touch, and to have numerous indurated projections, which felt very much like shot half embedded in the tissue, while the mere passage of the finger over it excited the most profuse hemorrhage. While making the examination I noticed also that the odor from the vagina was very offensive. It was not simply the smell of decaying flesh, but one that is indescribable and much more disagreeable than that.

This was all that I discovered; but, unfortunately, it was a great deal too much, for I recognized in an instant that we had here to do with an entirely hopeless condition—true carcinoma uteri. The patient's doom is irrevocably sealed. Under the most favorable circumstances I should think she might perhaps live a year longer, but hardly more than that. As she is entirely unable to understand a word of English, of course I am expressing myself much more freely in her presence than I would otherwise have done.

A year ago, a physician recognizing in the patient the condition known as cauliflower excrescence (which, by the way, I would have you understand is just as fatal as any other form of cancer), very properly amputated the cervix by means of the galvano-caustic

wire. In June last the operation was repeated, and now, at the end of a year from the first one and four months from the second, we find the cicatrix in the marked cancerous condition which I have shown you on the blackboard. Then, you perhaps will say, the medical attendant made a mistake in performing the operation at all. By no means; because, although it has not cured the disease, I have no doubt that it has materially prolonged the woman's life. There is a patient of mine who had the same trouble, and upon whom I performed a similar operation nine years ago. Being a widow at the time, she married again very happily, and she is to-day apparently in excellent health; but still I firmly believe that she will eventually die of cancer. This is a very exceptional case, but I have known a number of others to live as long as three years. Sooner or later, however, the disease, in my experience, always comes back again.

There is a physician's wife in this city who was in a most dreadful condition a year ago, upon whom I performed amputation of the cervix, and who has since then been perfectly well. Up to the present time there has been no new development of the disease whatever, but I am almost certain that during the next twelve months it will return. Yet who shall say that we have not gained a great deal by this happy respite. I am therefore strongly in favor of the operation in properly selected cases. In the present instance, however, no operation whatever would now be of the slightest use. What then; shall we let the woman die without any effort to prolong life or render her comfortable? By no means. There are three things which we can do, which will be of the very greatest service to her, viz.:

1. Control the hemorrhage.
2. Relieve the pain.
3. Disinfect the offensive discharge.

The plan that should be pursued here is as follows: first, the vagina and uterine cavity should be rapidly cleansed with absorbing-cotton, and then chemically pure nitric acid should be thoroughly applied to all the diseased surface. This will undoubtedly control the loss of blood for a time, and it may perhaps be unnecessary to repeat the application for as much as three months.

For the relief of the pain the treatment is all summed up in one word, and that is *opium*. This divine drug entirely overshadows all other anodynes, and you are merely trifling with your patient when you substitute for it hyoscyamus, chloral, or any other medicine whatever. If it should disagree with her at first, you can easily educate her to become an *opium-eater*, and nothing short of this should be aimed at by the medical attendant. There is a natural tendency in the human race to take to opium, as there is to alcohol, and in such a case as this you can have the opportunity of ministering to this natural craving with a perfectly clear conscience. You will find, therefore, that the patient who at first perhaps could not take even a small dose of opium without the most unpleasant consequences, will soon be looking forward with absolute pleasure when the drug is to be administered. If it does not suit her stomach, however, give it by the rectum; and should that disagree with her also, you have that most glorious method of relieving human suffering ever invented—the hypodermic syringe—left to fall back upon. It should be your object to control the pain at all hazards; and when in any case I hear the physician say that opium will not do this, I am very certain that the fault is with him and not with the drug, because he has never learned how to use it properly. Opium is just as sure to con-

trol pain as a leaden ball shot from a pistol or rifle is to kill a man if it is put into the right place.

The third indication is to overcome the disagreeable odor of the discharge; and this is to be accomplished by very copious vaginal injections, three times a day, of water containing a sufficient amount of thymol or carbolic acid to act as a disinfectant, and some such simple astringent as alum or sulphate of zinc.

Under this treatment you will be surprised to find the patient improving so rapidly that she will think she is certainly getting well. Many instances are on record in which the physician has also been deceived by the apparent recovery of his patient, and has rashly rushed into print in reference to the case, only to find his hopes suddenly dashed to the ground by its fatal termination.

In such cases it is food that the patient requires, in as large quantities as can possibly be digested, and not medicine; for it is useless to give iron, the hypophosphites, and other remedies which have been lauded as of the highest service. The patient is really starving in the midst of plenty, because her food is not converted into blood. And this is true of both animal and vegetable diet. Of all articles of food that I am acquainted with, milk is by far the best adapted for these cases. Some years ago a certain quack obtained a great reputation in the treatment of cancer of the uterus, simply because he employed an almost exclusively milk diet in his cases. At first the patient should take about six ounces of milk every three hours, and afterward the same quantity every two hours during her waking hours. In some cases, however, it is necessary to begin with only two ounces, or even one ounce. As soon as practicable, a large amount of cream should be added, so that the patient may get about two ounces of cream to every four ounces of milk. It will be better still if she can take three ounces of each every two or three hours; and it is a good plan to keep some of it by her bedside, in order that she may drink of it whenever she happens to wake through the night. By such a course of treatment as this, I have not the slightest doubt that the patient can be very greatly improved; but she will not, alas! be cured. A great deal will be gained, however, if by this means we can remove some of the evils from which she is suffering to-day, thus prolonging her life and ministering very materially to her comfort.

—♦—♦—♦—

CODEINE IN THE TREATMENT OF DIABETES.—The great value of opium in diabetes has long been recognized, and its use has suggested that of codeine, which must now be placed amongst the drugs that occasionally do much good in that disease. A case treated with it has been reported to *Paris Médical*. The patient, a woman aged twenty-three, was put on a diet of skimmed milk, eggs, beans, and green vegetables. The specific gravity of the urine was 1043, and the daily amount of sugar, $\frac{3}{4}$ ss. Various drugs were given without any permanent amelioration. Finally, codeine was administered in grain-doses twice a day. The patient began at once to improve, gaining flesh and passing less urine. In two weeks the amount of sugar passed was only about two drachms.

SCLERODERMA.—A case of this affection about which there has recently been much discussion, has been published by Dr. Armaingaud, of Bordeaux. It was treated with much success by the continued current after iodide of potash and vapor-baths had entirely failed.

Original Communications.

ON THE VALUE OF THE GALVANIC CURRENT IN EXOPHTHALMIC GOITRE,

AS ILLUSTRATED IN THE TREATMENT OF FOUR CASES.

By A. D. ROCKWELL, M.D.,

OF NEW YORK,

ELECTRO-THERAPEUTIST TO THE NEW YORK STATE WOMAN'S HOSPITAL, ETC.

THE opportunities for post-mortem examination in cases of Graves's disease have been so few that its pathology is far from being satisfactorily ascertained. It is true, that very positive results have rewarded certain researches into the condition of the sympathetic.

In eight cases structural change was discernible, although in a number this change was so slight as to be hardly recognizable, while in four cases not the slightest lesion could be detected. It seems fair to conclude, therefore (accepting the neurotic theory of the disease, rather than Basedow's hypothesis of a primary chlorotic affection, or the cardiac theory of Stokes), that the symptoms of exophthalmic goitre may proceed from purely functional, as well as from organic diseases of the sympathetic.

In those cases that resist every form of treatment, it is to my mind quite probable that examination of the nerve would reveal greater or less diminution of the nerve elements, together with gray infiltration and increase of the connective tissue, since these were the most important changes observed in the eight cases alluded to above, while results such as I am about to record can only be obtained when the condition is a neuroses pure and simple.

CASE I.—The patient, John L——, was a pale, slim man, aged 29, and by occupation a compositor. The three cardinal symptoms of the disease, viz.: exophthalmus, swelling of the thyroid gland, and palpitation, were present in a marked degree, and in addition there was a want of harmony between the movements of the upper eyelid and eyeball, a phenomenon first observed by Von Graefe, and by him regarded as pathognomonic.

The history and antecedents of the case are as follows: The mother, now deceased, suffered from epileptic seizures from the earliest remembrance of our patient, while an older sister was the victim of frequent and severe attacks of hysteria. The father had been intemperate, and died of delirium tremens. It would thus seem that we had in this history ground for a belief in the importance of the relation of hereditary influences to these conditions.

The health of the patient up to his twenty-fifth year had been uniformly good, and the only evidence of a neurotic predisposition was an occasional and unexplainable tendency to insomnia for a year or so previous to the first symptoms of his disease. I first saw the man July 6, 1879.

During the summer of 1878 he observed a slight swelling of the thyroid; very soon after, considerable palpitation; and later still, protrusion of the eyeballs. It is to be noted in passing that the order of the onset of the symptoms is unusual, the thyroid enlargement usually being second in order of development instead of first.

On my first examination I found the gland enlarged to about the size of the fist of a child of ten years, the pulse beating in frequency 125 to the minute,

while the protrusion of the globe of the eye was as great as in any case I have seen. By subsequent examination I found that the pulse ranged from 110 to 130. On three different occasions, where the axillary thermometer was used, it marked 100°, 101°, 100.4°. The appetite of the patient was poor, his secretions disordered, and his general strength impaired. After some preliminary medication of a corrective nature, I gave the ordinary prescription of quinine and iron, and at the same time began the applications of the galvanic current. My method of application was as follows: Placing the cathode over the ilio-spinal centre, and the anode in the auriculo-maxillary fossa, I gradually drew the latter, after a few moments of stable treatment, along the inner border of the sterno-cleido muscle, to its lower end. Removing now the anode to the position occupied by the cathode, and the cathode to the pit of the stomach, I would continue the treatment with a greatly increased strength of current for some moments longer. My ordinary measurement of current strength is by the "slant" galvanometer of the long coil variety.

During the first portion of the operation described, the current was sufficiently strong to deflect the needle 15°; during the last half of the operation, the deflection was increased to 30°. In other words, as a freshly charged zinc-carbon battery of regulation strength deflects the needle about 1° for every cell, a current strength equivalent to fifteen and thirty fresh cells was used. In point of fact, however, as some deterioration in activity through previous using had occurred, from twenty to forty cells were employed. The results of this treatment were immediate and of the most positive character.

The force and rapidity of the heart-beats were greatly modified; and accompanying, or rather following, by a week or ten days, this subsidence of the violent palpitation, there was a very noticeable decrease of the exophthalmus. A decrease in the size of the thyroid was not observed until some days after, and disappeared with much less rapidity than the other symptoms. In order to hasten the cure, I very carefully performed electrolysis on two occasions, and with evident benefit.

At the date of writing, Aug. 20th, after having received fifteen (15) applications, the patient has, so far as relates to the palpitation and exophthalmus, entirely recovered.

The goitre has decreased in size fully two-thirds, and is quite hard and firm, a change which is to be attributed, in all probability, to a hyperplasia of the glandular tissue taking the place of the dilated vessels.

From this time forward the important point in this somewhat remarkable case will relate to the degree of permanency of the apparent recovery.

I place the following case on record, not only because of the benefit accruing from treatment, but as illustrative also of two rare symptoms in connection with Graves's disease, viz., 1st. Dilatation of the pupils; 2d. Swelling and pulsation in the region of the solar plexus. I am not, indeed, aware that any case of Graves's disease, in which this last symptom may have possibly been observed, has ever before been published.

Accepting the theory of a disturbance of the sympathetic as a cause of this affection, it is not remarkable that its lower, as well as its upper ganglia, should be the seat of disease, sufficient to cause a dilatation of the vessels branching from the colicæ axis, analogous to that observed in the arteries of the thyroid gland. In consideration of the rarity of this symptom, therefore, it is interesting to recall the fact, that in the eight cases where changes were observed in the sym-

pathetic and its ganglia, they were confined to the cervical portion, the thoracic and abdominal sympathetic being entirely healthy.

In this case there must necessarily have been marked disturbance of the lower ganglia, but the complete and permanent disappearance of the gastric swelling would seem to preclude the probability of the existence of any lesion.

In the very few cases of exophthalmic goitre in which dilatation of the pupils has been observed, the cause is supposed to be due to a "paralysis of the pupillary branch of the oculo-motor nerve, consequent on neuro-paralytic dilatation of the vessels. The isolated paralysis of this branch (the other fibres of the motor oculi remaining unaffected) is referred by Stellwag to the fact that the branches destined for the pupil do not join the other oculo-motor fibres until after the latter have crossed the *crura cerebri*, and that they have been proved to originate from several centres of various function."

CASE II.—Mrs. G—, aged about 40, came to me for the relief of an exophthalmic goitre, May 3, 1876. The eyes were much protruded, the thyroid prominent, and the cardiac palpitation violent. The average frequency of the pulse was about 115, but on various occasions I found that it was beating at the rate of 140 to the minute. The patient was annoyed by profuse bilateral perspiration, *the pupils were enlarged*, and vertigo was a frequent symptom. The appetite was generally good, but she complained of much nausea.

She referred to one other symptom, which, if related to the disease as an effect, as it would seem, was quite new to me. Subsequent to the development of the three cardinal symptoms, which occurred in the following order—palpitation, thyroid enlargement, exophthalmus, a swelling appeared near the pit of the stomach, which in size and vigor of pulsation was more marked than the goitre. I may remark that Dr. S. S. Purple, of New York, had attended the patient in several confinements, and was cognizant of the disease in question.

Dr. Purple informed me that she had suffered much from malarial poison, to which, together with the effects of a labor of some severity shortly previous, might possibly be attributed the symptoms in question. The first signs of the disease were manifest some three years before she came under my observation.

I administered to this patient seventeen applications, ten of which were with the galvanic current, locally applied, while seven were with the faradic current, and were more general in their nature. Amelioration followed very quickly, and at this date the only symptoms of the disease is an almost imperceptible swelling of the thyroid, and, in a modified form, a tendency to occasional cardiac palpitations.

CASE III.—A middle-aged man applied to me on the last day of my service at the Demilt Dispensary, some seven years since, presenting the ordinary symptoms of exophthalmic goitre. I can, unfortunately, find no notes of this case, but, if I remember rightly, the difficulty had *not* been a long time in developing.

The man had been a hard drinker and was in ill-health. I treated him faithfully for some weeks—long enough to accomplish something, had it been possible—but I cannot remember that he was so fortunate as to experience any relief of a positive character. He ceased his visits abruptly, and never returned.

According to the record, the attempt in this case must be regarded as a complete failure, and yet,

through the improved methods and appliances of today, it is quite possible that a better result might have followed.

CASE IV.—Mrs. H—, aged 42, came from Newark, N. J., March, 1877, for an opinion, both as to the probability of benefit from an electrolytic operation upon a large goitre, and for her general condition.

The tumor had been coming for many years, and at intervals had been treated by various methods, among others, by injections into the substance of the growth, which resulted in some diminution in size, but at the same time set up an ulcerative process, which was a long time in healing. Her general health was very poor. She was greatly emaciated, suffered almost constantly from nausea, and was unable to retain sufficient food for proper nourishment. The pulse was from 85 to 90, and through mental or physical disturbance would rise 10 to 20 beats. It seemed probable that there was disease of the sympathetic, but there was no protrusion of the eyes.

The goitre was the largest that I had ever treated, approximating in size the two fists of a man.

The patient was first submitted to external galvanization (daily) of the growth and of the sympathetic. In two weeks there was a reduction, by actual measurement, of two and a half inches. At the end of a month no further reduction was observable, but every other symptom had been very decidedly ameliorated. The patient had increased immensely in strength and considerably in weight. The pulse ranged from 70 to 75, and was not at all susceptible to sudden fluctuations. The nausea had disappeared, and the appetite and digestion materially improved. The needles were now resorted to. Introducing three—connected with the negative pole—at equal distances at the base of the tumor, and applying an electrode, covered with chamois skin, directly over the central surface of the goitre, the circuit was closed, and the current from forty Siemen and Halsk's cells was allowed to pass for eight minutes.

At the end of a week, after a single repetition of this process, the original measurement had decreased five inches. During the next two weeks the electrolysis was twice repeated, the last seance being attempted with the ordinary zinc carbon elements, of which twenty were used. The tumor continued to grow smaller until the middle of May, when it was barely perceptible.*

These, with other recorded cases, being sufficient therefore to establish the fact of the value of electricity in exophthalmic goitre, the question naturally arises whether its beneficial effects are susceptible of rational explanation. It is quite evident that in this disease the sympathetic is at fault, but whether the dilatation of vessels, which are such important factors in causing the thyroid enlargement and exophthalmus, is of a passive nature, due to paralysis of the sympathetic, or of an active nature, due, on the contrary, to an irritation of the dilator fibres which run in the sympathetic, is open to question.† Accepting either theory, we find ample ground upon which to base indications for the use of the galvanic current. In case we accept the irritant theory, the very powerful sedative effects which may be obtained from the remedy is a sufficient explanation of the *rationale* of its use; while the fact that both physio-

* The above case was published in the February number of the *Virginia Medical Monthly* (1879), but in order to make the record of my cases complete, I may be excused for giving it again.

† The suggestion that the arterial dilatation is due to irritation of the dilator fibres is offered by Benedict, based upon the experiments of Bernard, Schiff, Ludwig, and Loven.

logical investigation and clinical experience has shown that electricity is the remedy *par excellence* for most forms of paralysis, quite clearly points to its use in cases where there is actual paresis of the nerve itself. In addition to the hyperæmia of vessels as a cause of exophthalmus, there may be also accumulations of fat in the cellular tissues of the orbit, which is probably the main cause in certain cases why the protrusion of the eyes still remain prominent after a decided amelioration of every other symptom.

CHRONIC AFFECTIONS OF THE MUSCLES FOLLOWING TRICHINOSIS.

By EDMUND C. WENDT, M.D.,

NEW YORK.

In the April number of the *American Journal of Medical Sciences*, for the year 1878, I published an account of certain chronic muscular symptoms occurring in a number of persons who had previously undergone trichinous invasion. The views advanced in that article were based on observations made on a group of individuals that constituted one family. I need not enter upon those views here. It is essential, however, to state that I regarded the cases as instances of chronic myositis, with acute exacerbations, due to the presence of innumerable foreign bodies in the voluntary muscles. I present the following case in confirmation of my opinion as stated in the paper mentioned. The history is taken from the records of the German Hospital, at which institution the case was observed, during my service there as resident physician.

Mr. A. B—, aged 23, native of Germany, one year in this country; was admitted April 26, 1878, with the following statement: Has never been seriously ill prior to present sickness; parents living; healthy; his habits temperate. For some days he had been "feverish," in great bodily pain, sleepless, very thirsty, and had complained of loss of appetite. He had perspired profusely; remembered having had diarrhœa about ten days ago. Several days previous to admission he had suddenly been seized with violent pains in the limbs, shoulders, neck, groins, breast, and back. These pains had not left him since then. He could adduce no cause for his severe symptoms.

The physical examination revealed slight bronchial catarrh, inadequate to account for the evident embarrassment of respiration. No lesion of inner organs was discoverable; there was some œdema of the lower extremities, puffiness of the face, especially marked about the eyelids. The examination of his urine proved the absence of renal complications; deglutition impaired; mastication quite painful. The most prominent symptom, and the one which had so largely attracted his painful notice, was the existing soreness and stiffness of the muscles. Almost all the tangible muscles of his body were exquisitely tender to the touch, every movement occasioned pain, and in attempting to go about he moved on tip-toe. The deltoid muscles, the gastrocnemii, the pectorales, the serrati, the muscles of the neck and thigh, were the seat of painful indurations, varying in size from a cherry to that of a closed fist.

The evening temperature rose to 104 $\frac{2}{3}$ ° F., with nocturnal remissions to 102° F. Respiration did not exceed 38, and was superficial, owing to the pain attending the effort of deep breathing. There was slight diarrhœa, the tongue moist and thinly coated. Diurnal quantity of urine diminished: color, dark red; no albumen, sugar, or casts.

The consideration of these symptoms left no doubt as to the nature of the malady. The patient was an Israelite, but on being closely questioned he admitted having eaten some raw ham about two weeks ago.

For a time the symptoms continued in their severity, then they gradually abated, and he made a fair recovery. He was discharged for after-treatment at home on the 7th of May; he continued to improve, and was able to resume his former occupation by the end of the month.

He passed from under my notice until fourteen months later; he came to me with a long tale of most annoying complaints, very surprising to him, almost equally so to the family physician, and withal scarcely to be endured. From his rambling remarks I gather the following: He had never entirely regained his former strength and muscular prowess, having been a very powerful man, of excellent physique, before his attack of trichinosis. About six months after leaving the hospital he had quite suddenly become subject to great muscular distress. The attack lasted several days, and in spite of energetic anti-rheumatic treatment, has from time to time repeated itself with unchanged severity. Muscular exertion, which he had previously taken great delight in, had now become a source of extreme suffering, so much so that he had latterly discontinued all active exercise.

But even during inactivity he was liable to be seized with spontaneous pain and soreness, most frequently affecting the flexors and extensors of the limbs. He further stated that these pains would sometimes become so intense that every movement of the body was instinctively shunned, and his condition was bearable only when he remained motionless. At other times his only complaint was a peculiar feeling of soreness in the calves of the legs, the pains occasionally shooting upward and downward. This condition his physician had characterized as one of neuralgia, but his treatment had secured no benefit to the patient. Similarly the arms would become affected, and so on, successively, the different muscles of the body. The shifting nature of these phenomena, and their apparent independence of palpable causes, were excessively annoying to his mind. He said, owing to these seemingly absurd complaints, he had become the laughing-stock of his companions. An old friend told him probably he was not yet over his growing days; he attributed his morbid sensations to *growing pains*; he was forced against his will to acquire habits of indolence.

The treatment advised by his physician had afforded no relief. Independently of all medication the attack would pass off, and a period of absolute freedom from all morbid manifestations would follow. This period of immunity would vary from a few days to several weeks. An examination showed no internal complication. All the functions of his body were normally and regularly performed, and save for the distressing tendency to muscular pains, he enjoyed excellent health.

When told my opinion as to the nature of his singular troubles, and after I had explained to him the causal relation they bore to his attack of trichinosis, he expressed his surprise that the same thought had not before occurred to him; for he said he had already noticed the marked predilection of the pains in favor of those groups of muscles which had been most troublesome at the primary invasion fourteen months ago.

This case appeared to me to merit publicity as corroborating the views previously expressed in conjunction with the cases cited in my former paper.

And I may now be permitted to state a belief already suggested by the study of my previous cases, but which I had hesitated to openly express at the time, *i. e.*, not a few cases accepted and treated as instances of muscular rheumatism, are indeed cases of chronic myositis, with acute exacerbations following trichinosis. It is precisely in this consideration that I find the practical importance of the matter under discussion.

It is well known that slight attacks of trichinosis frequently escape recognition. It is equally well known that rheumatismoid pains of a shifting nature form a prevalent complaint. The occurrence of trichinosis in our country is an established fact, though for various reasons its frequency is generally underestimated. We lack extensive statistical data, such as are furnished by European writers. Strict official surveillance and the microscopic examination of pork by competent authorities have not yet been established in our country. Only very severe or fatal cases are brought to public notice, and these are frequently discovered only by accident. Still, the disease prevails. Official reports on the subject have shown the percentage of infected swine to be especially large in America.

In Europe, people are already warned against pork exported from the United States. The danger in our country is comparatively small, because it is not customary here to eat uncooked ham, sausage, etc. On the other hand, cooking is no absolute safeguard. All this tends to show that the accepted notion, according to trichinosis a place among the rare diseases, cannot but be erroneous.

To return to my point, these considerations will, if I am not mistaken, establish a certain connection between trichinosis on the one hand, and many so-called rheumatismoid affections on the other. As regards the treatment of such cases, I have little to add. Owing to the impossibility of destroying the muscular trichinae, we are restricted to adopt such symptomatic measures as the exigencies of the individual case seem to suggest. I have found hot baths quite beneficial in allaying the milder attacks. Narcotics must be resorted to when the pains are suddenly developed. Rest and frequent rubbings with anodyne liniments sometimes afford relief. Of course, our only reliable safeguard is an efficient prophylaxis. Some system of rigid microscopic inspection should be adopted in our country, and the sooner we get it the better.

TRAUMATIC DISLOCATION OF THE FIFTH CERVICAL VERTEBRA.

ONE WEEK'S DURATION; IMMOBILITY AND DISTORTION OF HEAD AND NECK; PARALYSIS OF ARMS AND LEGS; INABILITY TO SWALLOW FOOD; REDUCTION BY SUSPENSION BY THE HEAD AND ROTATION OF THE BODY.

By WM. J. MORTON, M.D.,

NEW YORK.

THE following case came under my care as clinical assistant at Professor Hammond's clinic for Diseases of the Mind and Nervous System, and offers some points of general interest.

The patient, Tommy Baedor, a bright boy, twelve years old, was referred to the clinic on account of general paralysis of his arms and legs, and apparent contractions of the muscles of the left side of the

neck. He gave the following account of himself: One week ago he was running very fast, chased by another boy, who, as he caught up with him, pushed him violently. He fell and struck the right side of his neck against the horizontal iron rod of a fence or railing. The shock was severe, and he could not speak for several minutes. He was helped up and home. His neck felt very sore and was "twisted" to one side. His aunt applied liniments, without, however, producing any relief. Upon trying to drink he found that he had a "lump" in his throat which hurt him very much when he swallowed, and he was obliged on this account to eat only soup and soft food. Moreover, he could not open his mouth wide. He tried to get a peach stone between his teeth, using it as a wedge to force the jaws apart, but could not get it fairly in. He was obliged to sleep on his right side. The next day he felt very weak, could not swallow without much pain, couldn't walk, nor get his mouth wide open. His aunt states that "his hands felt in a burning fever," while his body felt cool. During the remaining five days he was unable to use his arms and hands; they were "paralyzed, and had no feeling in them,"—so much so, that, he says, he could not use them to pull his trousers on. He also felt very sleepy. He made many ineffectual attempts to get his neck straight. Finally, his aunt, who is a very dull sort of person, thought it time to have his case examined, and accordingly brought him to the clinic.

Present appearance.—As the boy entered, the first thought was of an extreme contraction of the muscles of the left side; the head was pulled strongly over to the left and backward, while the chin pointed out to the right; so marked was this position that the head seemed to lie over upon the left shoulder—the left shoulder at the same time was elevated and held up toward the ear. The rigid appearance of his whole body was peculiar; he seemed to walk as though in fear that his head would topple off; when he turned, the rotation took place at the hips and not at the neck, or he rolled his eyes without moving the head. His arms also swung a little stiff and helplessly, and were flexed at the wrists. The rigidity of the shoulder and neck region was very marked. When asked what he complained of, he stated that he could not use his arms; that he had no feeling in them; that he couldn't walk well, and that it hurt him to swallow even fluids. Examination corroborated his statement in regard to paralysis and cutaneous anaesthesia, as well as his inability to swallow water without evidences of pain. It caused pain also to produce forcible extension of the flexed wrists. Told to put out his tongue, he could not open his mouth more than half an inch, but the tongue came out straight. It was coated white on the right side, clean and red on the left. There was no discoverable paralysis of the muscles of the face or eyes. As regards the position of his head, the occiput seemed to sink downward and backward, and give to the chin an upward projection; the chin, as mentioned, projected over the median line to the right side. Between the base of the occiput and the seventh vertebra the outline of the spinal column seemed to hollow in, and the spinous processes to be obscure. It was difficult to feel the spine of the fifth, and pressure over it gave pain on both sides, but particularly on the right. The head could be bent over to the left side moderately well, but could not be laid over on to the right shoulder in the slightest degree. In this direction it was perfectly immovable.

There was no evidence of a permanent contracture as in torticollis, nor of paralysis of the muscles of the right side. There was no crepitus at the seat of in-

jury, and the fact that the deformity could not be in the least degree modified by lateral rotation seemed to justify the exclusion of a diagnosis of fracture, at least of an oblique process.

A diagnosis of dislocation of the inferior oblique process of the fifth cervical vertebra was made, and an attempt at reduction determined upon. I may say that Dr. Osborne, who by chance was present, concurred in this diagnosis.

Moderate extension was first tried, but to no purpose. Finally, taking the boy by the head and under each mastoid process, I lifted him gradually entirely clear of the floor and held him suspended, an assistant at the same time supporting my elbows. His body, with the right shoulder as a guide, was then rotated by Dr. Osborne, first very gently backward, *i. e.*, to the right (as the hands of a watch indicate), in order to disengage the oblique process, then more firmly forward, *i. e.*, to the left; the jar of the bone returning to its place was immediately felt both by Dr. Osborne and myself, though much modified, of course, by the weight of the patient's suspended body. The patient was immediately lowered so as to stand on his feet, and to our pleasure the head was quite straight, though still a very little bent over laterally to the left side, a condition due probably to its having been so long already in that position. But it was particularly noticed that the chin pointed straight again. The boy expressed his relief and satisfaction, and rotated his head freely to demonstrate that it was now in its right position. Given a glass of water he drank it off freely—a thing he had not been able to do for a week when sent home. At the end of two hours the head was quite straight. Sensation had not, however, returned to his arms and hands. He had at times a thrilling feeling in them, as if his "crazy bone" was being hit. Patient walked home.

Friday, July 25th.—When patient woke up he found he was unable to move except very gradually. For instance, he woke with his hands crossed and had to get his aunt to separate them. His feet were much swollen, as also his hands and wrists. He could barely hobble along, walking on the outer edge of his feet. His hands felt numb all day; he could not close his fingers nor hold any object in his hands; could move his thumbs best. Both hands were alike. He was so helpless that he had to be put to bed; had no trouble of urination, but was constipated.

July 26th, Saturday.—Felt much better; could use his arms and legs pretty well. The dorsum of the hands was much swollen; pulse, 84. A painful spot, like an enlarged gland, is felt in each groin. Bends head freely forward but not backward. Bends it well to his left side, but not to his right. Right cheek swollen; right side of tongue coated white—left, red; painful enlarged gland under right jaw; pupils normal. Spines of cervical vertebrae in line.

July 27th, Sunday.—Swelling has left his hands; movements improved; still holds his head very slightly crooked. Pulse, 65.

Monday, July 28th.—Head quite straight. Swelling of hands has disappeared, and sensation and motion have thoroughly returned to them. Still places the finger over the fifth cervical vertebra to indicate the region of a remaining sore spot in the neck. Pulse, 81.

Tuesday, July 29th.—Slept without pain in the neck for the first time since injury. Head carried perfectly straight. Patient apparently in all respects completely recovered.

September 29th.—Patient, up to this date, has remained as well as if no accident had ever happened.

CLASS-ROOM LESSONS ON CHANCROID, GIVEN AT THE COLLEGE OF PHYSICIANS AND SUR- GEONS IN THE CITY OF NEW YORK.

By FESSENDEN N. OTIS, M.D.,

CLINICAL PROFESSOR OF GENITO-URINARY DISEASES,

[FOR THE MEDICAL RECORD.]

III.

DIAGNOSIS OF TRUE CHANCROID—CHARACTERISTIC FORMS OF THE CHANCROIDAL LESION—MODIFICATIONS.

GENTLEMEN:—In the previous lesson the diagnosis of simple origin of the apparent chancreoid was made in the last case presented.

It is, however, very evident that if no lesion is to be accepted as a chancreoid unless proved to have arisen from contact with a lineal* chancreoid, the specific nature of chancreoid may be accepted as demonstrated. The diagnosis then, in any instance, will not rest upon the character of the lesion, but upon its source. Thus, in the case cited, according to this ruling, we have not a chancreoid. A suppurating sore occurs in a lady who never before had an ulcerative lesion of any sort; it makes its appearance on the urethral orifice a few days after contact with her husband, who has a sore of his urethral orifice, which appeared a few days after a contact with another woman, and was followed by a suppurating bubo; it looks exactly like a typical chancreoid; it behaves like it in its destructive tendency, in its advance and its retrograde under treatment, and its final cicatrization after about two months' duration, under improved hygienic conditions, and yet it is not accepted as chancreoid, and why? First, because it is clearly not the product of a lineal chancreoid. This is, of course, sufficient for those who thoroughly accept the specific nature of the disease; but there are others who decide this lineal matter by the inoculability or non-inoculability of its secretion; with them the production of true chancreoid, by inoculation of a given secretion, proves that secretion to have come from a chancreoid. Assertions to this effect would appear to be the result of experience among the class most prone to suffer from the results of venereal dissipation, where probabilities are all in favor of chancreoid having been acquired from contact with chancreoid, and among whom the contagious element of the chancreoid is kept by various influences up to a high point of activity.

There can be, however, no question that chancreoid, proven of direct lineal descent from a typical chancreoid, may be met which is inoculated with difficulty, and which is but feebly destructive; that, in point of fact, chancreoid descended from typical chancreoid is seen of every grade of destructive and contagious power. Experiments have proved that the true chancreoid virus gradually loses its power by repeated inoculation, and also that various conditions of health may prevent the success of inoculations with fresh virus, and under circumstances otherwise favorable. "Susceptibility to inoculation is impaired, or even lost, temporarily, during the occurrence of any febrile attack or great depression of the vital powers."[†]

It is also increased by constitutional dyscrasia of various kinds: thus the syphilitic dyscrasia, it is well known, predisposes to purulence. Typical chancreoid, destructive and inoculable in generations, have been

* *i. e.*, descended in unbroken line from the first chancreoid, as claimed by those who assert its specific origin.

[†] Buntford, p. 47.

repeatedly proven to result from the inoculation of pus from an irritated syphilitic chancre, also from the purulent secretion of secondary syphilitic lesions, and also from scabies and acne. Baumler, a recent German authority, says: "According to its source and mode of its origin, as well as the susceptibility of the individual affected, will the pus poison and evince this (chancreoidal) property in greater or less degree.

*Whence the pulse derives this property, in what it consists, and why all pus does not possess it alike, are questions yet to be solved.**

Inoculability, then, is not a reliable test as to the origin of a sore.

Again, inoculation of a leucorrhœal secretion, especially from a cervicitis or a metritis, has been claimed capable in certain instances of producing inoculable sores. This is further proven by the following extract from a distinguished authority:—

"In March, 1840, a woman† from the neighborhood of Arles, aged 22, and remarkably beautiful in form and appearance, was thoroughly examined, as was supposed, by Prof. Lallemand, and no symptom of venereal disease was discovered. This examination was made at the request of an officer, who complained that she had infected him; and several similar complaints being subsequently made by others, she was sent to the police station, where she was again examined by M. Delmar, in the presence of a considerable number of students. *The neck of the uterus still appeared healthy, but on pressing it with the speculum it discharged a muco-purulent fluid, which was inoculated in four places upon the patient's thigh, with the effect of producing four well-marked chancroids.*" In this connection it will be interesting to recall the cases in the previous lesson where ulcerative lesions on the penis resulted upon contact with virtuous women who suffered only with subacute metritis. How do these women differ from the beautiful woman of Arles as to the character of these uterine secretions? Contact with them produces sores proven to have a contagious property. Must we, then, say that they are the subject of chancreoid in the interior of the cervix or uterus? The woman of Arles communicated *chancreoid*, because she had a uterine leucorrhœa, and because she was a prostitute, not because she had chancreoid. The most rigorous and repeated examinations failed to find any chancreoid upon her, and yet she was the source of chancreoid to others. The man, whose urethral sore communicated a similar sore to his wife's urethra, had not chancreoid, because his sore was acquired from contact with menstrual fluid under circumstances of unusual excitement, from a lady of supposed virtue, and not from a prostitute.

The foregoing cases and remarks are chiefly intended as a preface to the final and important statement that the elements of destructiveness and contagiousness in a venereal lesion are not, in my opinion, dependent upon a *specific* virus, but are engendered by various causes and conditions; and that, clinically, we shall have to deal with venereal lesions in every degree of activity, which activity will be found to depend as frequently upon the constitution and circumstances of the patient, as upon the variety and origin of the sore from which his chancreoid was derived. We may then say that *chancreoid*—

1st.—Begins as a destructive process, either upon a pre-existing lesion, or upon sound tissue. It is usually set up by contact with the purulent secretion

of a *similar* destructive process, which had a *similar* origin, or which may have been developed from a *suppurative* process of a lower grade.

2d.—The destructive process thus initiated (either upon sound tissue or upon a pre-existing lesion) proceeds steadily to the formation of a pustule, or an ulcerated surface, by a more or less rapid molecular necrosis. This necrosis, occurring under differing conditions and in different localities, gives rise to characteristic forms of the chancreoidal lesion which may be described as follows, viz.:

1st.—*The Chancreoidal Abrasion*; 2d.—*The Pustular Chancreoid*.

These may be again divided into the *slowly destructive* and the *actively destructive* varieties. We may have as modifications of these,—

FROM CONDITION.	FROM LOCALITY.
<i>The Indurated Chancreoid.</i>	<i>The Follicular, Papulo-Pustular, or Aeneiform.</i>
<i>The Inflammatory Chancreoid.</i>	<i>The Ecthymatous.</i>
<i>The Gangrenous.</i>	<i>The Bubonic.</i>
<i>The Phagedenic.</i>	<i>The Urethral.</i>
<i>The Serpiginous.</i>	<i>The Rectal.</i>

The Ex-Ulcerous Chancreoid of Clerc and the Ulcus Elevatum.

Modifications of all the foregoing forms and varieties, by the *coincident development* of implanted syphilitic elements on the site of the chancreoidal lesion.

We will next study a little more in detail each of these characteristic forms of

THE CHANCREOIDAL LESION.

First.—As to the *origin of the Chancreoidal Abrasion*. Abrasions of mucous membrane are frequent as the result of violence during the act of coition; they occur most frequently about the fourchette and the vestibule of the female, and about the preputial orifice and the frenum, and along the preputial reflection of mucous membrane behind the fossæ glandis in the male.

All injuries of this character, on being brought into contact with the secretion of an active chancreoid, are at once inoculated, and the suppurative action is thus initiated over the entire surface of the lesion. It is to the abrasion, thus complicated, that the term *chancreoidal* is applied. To the naked eye it appears at first like a simple scratch or chafe, but an examination of its secretion shows abundant pus corpuscles, within three or four days, and often within twenty-four hours. By the aid of a good magnifying glass, the advancing molecular necrosis may be seen, in the dentated edges, in the minute, sloughing points on the surface of the lesion, and the secretion is inoculable. Sooner or later, in accordance with conditions which are known to render chancreoidal lesions more or less active, the abrasion may be merged into the characteristic chancreoid. Its shape, which at first corresponds with that of the surface inoculated, now changes through the advancing ulceration; the edges become ragged and abrupt, the floor, excavated and covered with the debris of disorganized tissue, gives rise to a profuse secretion of pus. The time for these changes in different cases may vary from a few days to several weeks.

Second.—As to the *origin of the Pustular Chancreoid*.

The pustular chancreoid arises either from the erosive property of the chancreoidal secretions which have been deposited in the folds of integument or mucous membrane, or from the absorption of the secretion into the follicles of mucous membrane, which have been bathed in the secretion of chancreoid.

* Ziemssen, Vol. III., Am. Ed., pages 94-95.

† Baumstead. p. 359.

The time of its appearance after contact varies from three or four days to eight or ten, and in certain authentic instances even longer.* Occasionally single, it is accompanied, as a rule, or soon followed, by others in the immediate vicinity or at different points. Commencing as a fine whitish speck, scarcely larger than a pin's point, it soon increases in size, and, unless occurring on an already inflamed surface, presents a distinctly inflamed border. Its progress (more or less rapid, according to circumstances and conditions which are known to increase or retard its activity) is by an acute ulceration, before which the tissues give way in irregular form, both at the edge and floor (as heretofore described in case of its advance from a previously abraded surface), accompanied with more or less local inflammation and pain. Its progress, like that of the chancreoid abrasion, is variable. In typical cases, under circumstances of usual health and condition, reaching to the size of a five-cent piece, and penetrating to the depth of one or two lines, in the course of three or four weeks, while, under other circumstances, its depth and its extent may be greatly increased.

These peculiarities of the action of the chancreoid are the same, whether beginning on an abraded surface or as a pustule, and warrant the division of chancreoid into the two forms previously noted, viz.: the *slowly destructive* and the *actively destructive*.

To show you that this division is not simply a technical one, I will recall four cases presented to you at our last two sessions, which illustrate the validity of the distinction.

CASE I.—Wm. B.—, waiter, about twenty-five years of age, gave a history of exposure through vicious sexual contact eight weeks previously. Four or five days after, he noticed several white pimples on his prepuce behind the *fossa glandis*. He touched them with "blue stone" from time to time, and after a

week others came on his glans penis. He then used a wash and kept them clean, but they refused to heal until he went to Charity Hospital about a week ago, seven weeks after their appearance. Here the sores on the prepuce were cauterized, on several occasions, with nitric acid, also three on the glans, about the size of a pea. His general condition as he came before us was fair, not rugged. He presented several superficial cicatrices on the internal reflection of the prepuce, and a raw surface about the size of a three-cent piece, yet unhealed, but granulating well. On the glans were three fresh cicatrices, which, as I was careful to show you, matched exactly upon three distinct cicatrices on the prepuce when drawn forward. This case I presented as chancreoid of the first variety; demonstrated as slowly destructive, and also contagious, as proven by auto-inoculation.

CASE II.—A blacksmith, aged forty-five, was shown you in contrast. A large, pallid man, evidently in low condition. Just two months before, he also had a connection, and no trouble resulted for the next ten days, when his attention was attracted to his penis by soreness. He then discovered three inflamed pimples, one on a redundant prepuce and two on the body of the penis. These progressed steadily, and thinking they were simple boils, he neglected them until the scabs came off a few days ago, when he found deep ulcerations in their place, each as large as a dime. He was admitted to Charity Hospital, and the sores, which were recognized as typical chancreoids, were cauterized with nitric acid. When shown to you, three days after, they were still of the same size before mentioned, and fully one-fourth of an inch deep, penetrating fully and sharply the swollen integument. This case was presented as illustrating the *actively destructive* variety of chancreoid. With much the same history as the first, it was yet seen to be in marked contrast with it in regard to the activity of the destructive process. There was no history of any antecedent syphilis in either case.

The third case was of a lad of 20. He was in good health, history of an impure connection four weeks previously; a pimple near the frenum appeared five or six days after; this he treated with repeated applications of "blue stone," and it healed in a couple of weeks, having carried away the frenum. A soreness of the right groin then set in and culminated in an abscess; this I opened before you, discharging about an ounce of unhealthy looking pus.

Both its appearance and course were spoken of as characteristic of the chancreoid bubo. The locality of the original sore was pointed out as one most liable to be followed by such an accident, inasmuch as the lymphatic vessels connecting this point with the glands of the groin are known to be numerous and superficial. No other cause for such a complication could be elicited.

The fourth case presented to you last week came to our clinic the week previous, too late in the hour to be available as an example. The young man, twenty-five years of age, gave a history of impure connection the week previously, and had just discovered a little sore just within the urethral orifice. A little feeling of hardness associated with this sore and the long interval since the connection, gave rise to suspicion of syphilis. In order to clear this up, two inoculations were made under the left nipple of the patient by Dr. Bangs, our chief clinical assistant, and the patient was ordered to report on the following Saturday, two days after; this he failed to do. He was presented to you one week after, with a sore which had penetrated fully one-third of an inch, and had completely

* The follicular starting-point of the disease assumed by Cellier, Bunschal, Arton, and others has been substantiated by a case which came recently under my observation. Mr. W— came to me complaining of having bruised his glans penis during a connection four days previous. On the morning following the indulgence the part felt very sore and was swollen and inflamed. These conditions had been gradually increasing in intensity until he presented his case to me. I found the inferior portion of the glans much tumefied from the meatus back to the fossa glandis, and for half an inch on either side of the median line (the frenum had been smoothly carried away by a chancreoid ulceration, for which I had treated him a year previous). The injured part was swollen, and presented a smooth, shining surface of a deep red color. By the most careful examination, with the aid of a magnifying glass, I could not discover any point of abrasion or solution of continuity whatever. I advised a simple water dressing, slinging up the penis, so that engorgement from the dependent position of the organ might be relieved, and as perfect rest as possible obtained. He called on the following day somewhat relieved, but in appearance the parts had not improved; the color was even deeper than on previous examination. A wash of lead and opium was substituted for the water dressing, and the patient advised to keep the recumbent position. On the next day, the third from his first visit to me, and the seventh from the impure connection, he again presented himself. The tumefaction was much the same; the color had deepened, and was now of a violet tinge, and I discovered, as though under a glass, numerous pale-whitish points varying in size from a pin's point to a pin's head, occupying a space a quarter of an inch broad, and one-third in length on either side of the median line on the inferior aspect of the glans. Previous treatment was continued, and I saw my patient daily for three days following, making in all ten days from the connection. On the morning of the tenth day I discovered some half a dozen whitish points just underneath the mucous membrane; these were then opened into with a fine pointed bistoury, and discharged minute quantities of pus. Under the magnifying glass, the little cavities left after the discharge of the pus were characteristic of chancreoid ulceration. In brief, all the points, some twenty or thirty in number, finally worked their way to the surface, occupying some three days longer, and they soon conformed from the extension of the ulceration process, resulting in a true chancreoid three-fourths of an inch in length by one-third of an inch in breadth, occupying the site of the original white points. The first pustules were visible through the mucous membrane, but evidently deeper than its thickness on the seventh day after the absorption. The first of these came to the surface on the tenth day, but it was not until the thirteenth that all had reached the mucous membrane on their outward march. Applications of the strong nitric acid resulted in a complete recovery in a few days.

carried away the right side of the meatus, exposing the urethra for that distance. The attempted inoculations, as shown you, were wholly abortive, although as I saw them one-half hour after the puncture they were surrounded by a congested areola of half an inch in diameter.

This case I presented as demonstrating several points: 1st. The long interval of apparent incubation. 2d. The slow progress of the lesion up to the week previous, thus marking it as belonging to the slowly destructive variety of chancre, if it were chancre. 3d. The sudden change from the slow to the actively destructive variety. 4th. The failure of a carefully performed inoculation of the secretion of the lesion upon the person of the patient, thus going to prove that a destructive chancre may, under certain conditions, fail to give an affirmative proof by inoculation as claimed by Böck and others.

Now, while I do not present these cases as absolutely proving the points I desire to illustrate (as there may be various valid objections urged against them), yet I claim that they form links in a chain of evidence, which may be forged to show that chancre is of variable quality and force, and also that the quality and force is determined not by any specific virus, but by circumstances and conditions. It will be well for all who study and treat this disease to be cognizant of this, and to consider the causes which are known to affect the degree of destructiveness and contagiousness in each case, instead of attaching too great importance to the dogmatic and unsupported assertions of those who claim one continuous lineal descent for all inoculable and destructive venereal sores.

It may, I think, be safely claimed that the character of a chancre is greatly dependant upon the degree of activity of its immediate predecessor, and that it may itself be modified or intensified by the following influences:

- 1st.—General condition of the person so inoculated, especially in relation to any diathesis or dyscrasia.
- 2d.—Locality of the inoculation.
- 3d.—Influence of alcoholic stimuli, low and irregular living, etc.
- 4th.—Local sources of irritation, such as standing at work, walking, or horseback exercise, indulgence in coitus, uncleanness.
- 5th.—Application of external irritants, administration of internal medicines, especially mercurials.

For the convenience of description, various names have been applied by authors to designate the several modifications of chancre. These have been already cited, and will be seen to fall naturally under two heads, as modified by condition and locality.

We shall consider next,

THE MODIFICATION TO WHICH THE DIFFERENT VARIETIES OF CHANCEROIDAL LESION ARE SUBJECT FROM CONDITION.

First:—The Indurated Chancre. The uncomplicated chancre has a soft base and edge, differing in suppleness, but little, if at all, from the surrounding tissue. In this condition we have a valuable diagnostic mark separating chancre from the initial lesion of syphilis, which in typical cases presents a distinct induration of the tissue on which the lesion is located. Venereal sores often present, however, about which a varying amount of induration is present; not seldom occurring at an early period in a chancre, before the loss of substance is well marked, or coming on later, in a well-marked chancre, giving rise to suspicion of underlying syphilitic action. It is well then to understand that

such induration may result from any form of irritation, and may be a purely inflammatory aggregation of cell material. Chancroids thus complicated are termed *indurated*. The test of the nature of the induration in any case is by treatment. If the induration is thus rendered more dense and sharply defined, it will prove, as a rule to which there are few exceptions, that it is the result of true cell growth, caused by the syphilitic influence, and that the lesion is either the initial of syphilis complicated by accidental ulceration, or that it is a true chancre complicated with syphilis.

If, on the contrary, the induration disappears wholly under the influence of rest and local sedatives, it is of an inflammatory character, and the lesion so complicated is proven of purely local nature, and has thus been but an *indurated chancre*.

Second:—The Inflammatory Chancre. Instead of becoming indurated under various causes of irritation as in the previous variety, the tissue surrounding and underlying the chancre may become more tender and swollen, assuming a puffy appearance, and the surface more intensely red and extended.

This condition may supervene upon any stage of chancre, whether slowly progressing or healing, and is the evidence that a more rapid destructive action has been initiated or is imminent.

The same condition may obtain on the early appearance of the chancre as a result of intensity in the secretion inoculated, or from constitutional taint, excess, sexual and alcoholic, as well as from local irritations.

The Gangrenous Chancre is but the fruit of the unrelieved inflammatory form, usually the result of interference with the circulation of a part by swelling and inflammatory infiltration of the tissues, in which case, sloughing of contiguous structures occurs *en masse*; especially is this apt to take place in debilitated and dissipated subjects. When occurring upon persons in good condition it is the result of some mechanical constriction, as in case of subpreputial chancroids complicated with phimosis.

The occurrence of gangrene, in such case, once announced by the fœtid odor, if not arrested by treatment, will require but a few hours for the deep red surface of the inflamed prepucium to turn black, and the slough to disintegrate and separate from the living tissue at or near the line of constriction. The effect of the gangrenous accident is to destroy all contagiousness in the associated chancre, and the parts heal, after the falling of the slough, as if no such complication had been present.

VENEREAL PROPHYLAXIS.—The subject of how to indulge the passions without physical injury or infection is made the subject of scientific study by a Parisian. In a work addressed to "Emile"—who represents the erotic class in general—the virtues of various forms and methods of protection are discussed in a broad and judicial style. Truly, Paris stands at the head of civilization.

BROMHYDRATE OF MORPHINE.—This drug is being used as a substitute for the sulphate. It is more soluble in water, and is twice as powerful. It combines the sedative effects of the bromine with the anodyne properties of the morphine. It is not so dangerous, and is not so apt to be followed by unpleasant symptoms. It is the drug especially for irritative affections of the spinal cord. This is claimed by Dr. Landrieux, in the *Journal de Thérapeutique*.

Progress of Medical Science.

MORBUS WINCKELII: A HITHERTO UNDESCRIBED DISEASE OF NEW-BORN INFANTS.—On the 19th of last March, a child in the Maternity Hospital, in Dresden, was taken sick with very peculiar symptoms on the third day after birth. This case was followed by others, constituting an endemic which lasted, with an interval of ten days secured by isolation of the patients, until the 21st of April. Twenty-three infants were attacked, and nineteen (82 per cent.) died, after an average sickness of thirty-two hours. Of the four who survived, one was cured, one was taken from the hospital greatly improved, and two were taken away while still laboring under the disease. The patients were attacked between the first and twelfth days of life, most of them on the fourth day. They were almost all born at full term; the labors were normal, and the mothers passed through the puerperal period without accident. Of the children attacked, nine were boys and fourteen girls; eighteen were nursed by the mothers.

The following account of the symptoms presented by the first child attacked after the ten days' interval is given by the reporter, Dr. Winckel, and will answer as a description of the disease: the mother was confined ten days after the last child had been attacked, and had watched once, before her confinement, in the ward in which the sick children were placed. Her child was robust, weighed nine and a half pounds, and cried lustily. It was put to the breast on the day after its birth, but it drank little and seemed dull. On the second day the characteristic symptoms were present: cyanosis of the entire body, conjunctivæ slightly jaundiced, sighing respiration, hæmoglobinuria, the urine being pale brown in color and passed frequently and with bearing-down movements. The urine contained also epithelium from the bladder and renal pelvis, granular casts with blood-corpuscles, micrococci and masses of detritus, urate of ammonia and albumen. The temperature was normal—in no case was there any fever. The condition of the blood was very remarkable. When a slight incision was made in a cyanotic spot, the blood did not flow unless forcible pressure was employed. It was as thick as syrup, and almost blackish brown in color. Microscopically, Dr. Winckel found an increase of the white corpuscles, quantities of small granules (debris of the red blood-globules), and small corpuscles with molecular movement. The abdomen was not distended, and was normally soft. Liver somewhat enlarged. Thoracic organs normal; heart-sounds somewhat muffled. Later on convulsive movements of the extremities and eyes set in, and a few hours afterward death took place in more violent convulsions.

Results of the Autopsies.—Umbilical vessels diseased in one case only. Liver swollen, dark brown, sometimes in a state of granular degeneration. Spleen thickened and enlarged. Pancreas excessively hyperæmic. Kidneys, the cortical substance brown, often with darker streaks; in the papillæ frequently hæmoglobine infarctions. Stomach always greatly dilated, sometimes like a balloon, presented a few ecchymoses. Below the duodenum a series of ecchymoses began, which were thickly sprinkled over the mucous membrane of the entire intestines; swelling of Peyer's patches; enormous swelling of the mesenteric glands; ecchymoses of the pleura. In the brain, œdema and dilatation of the ventricles; in the

membranes, marked hyperæmia and a few small extravasations, and, in a few cases, pronounced icterus. Etiologically, it is as yet only possible to say what the affection was not due to. It could not be due to the effects of the delivery, to puerperal infection of the children, to poisoning by morphine, opium, phosphorus, carbolic acid, or chlorate of potash, to errors in diet, or to the action of heat by baths given at too high a temperature; nor could any cause be discovered in the clothing or the air of the wards. The *agens morbi*, whatever it was, must have been very intense; it must have penetrated directly into the blood, and perhaps made its way into it through the digestive tract, as the most intense derangements were met with there.

Dr. Winckel calls the affection "cyanosis acerbilis ieterica pernicioza cum hæmoglobinuria," but it has been suggested to substitute for this formidable name the simpler term "*morbns Winckelii*."—*Deutsche Med. Wochen.*, 1879, Nos. 24, 25, 33, 34; *Centralblatt für Gynæk.*, July 19, 1879.

OCINUM BASILICUM, A NEW ANTHELMINTIC.—This plant, which is known in Buenos Ayres under the name *albahaca*, exerts a powerful action on intestinal worms, expelling them from their haunts with very great rapidity. The part used is the juice, and it is given in doses of about two ounces, followed in two hours by castor-oil. It acts more powerfully and certainly as a vermifuge than calomel, santonin, koussou, or kamala, and, on the other hand, possesses the great advantage of doing no harm if worms be not present, exerting then merely an aperient and disinfectant action.—*Allg. Med. Cent. Zeit.*, July 26, 1879.

TREATMENT OF TAPE-WORM BY SALICYLIC ACID.—Dr. Ridder reports two cases in which he gave salicylic acid to remove tape-worms, with the most satisfactory results. The mode of administration was as follows: An ounce of castor-oil was given in the morning, and the patient's diet was restricted during the day, so as to keep the intestinal canal as empty as possible. On the following morning half an ounce of castor-oil was given at 7 o'clock; at 8 o'clock 12 grs. of salicylic acid were given, and this dose was repeated every hour until a drachm of the acid had been taken; half an hour after the last dose, another half-ounce of castor-oil was administered. In one of the cases the worm was passed about 1 p.m., and in the other about 3 p.m.; both were examples of the *tania solium*, and both were passed entire, with the head. After the passage of the worms the rectum was washed out with injections of water. The only unpleasant effect produced by the treatment was a slight nausea, which was not, however, bad enough to keep the patients from returning to work on the same afternoon.—*Allg. Med. Cent. Zeit.*, July 30, 1879.

SCILLINE, SCILLIPICRINE, AND SCILLITOXINE: THE ACTIVE PRINCIPLES OF SQUILL. Squill, though deservedly placed in the first rank among diuretics, labors under the disadvantages of being uncertain in its action, owing to the difficulty of obtaining the bulbs in the proper condition, and of possessing an acro-narcotic principle which proves poisonous to some individuals, even when only moderate doses are taken. These disadvantages are now overcome, it is claimed, by Merck, of Darmstadt, who has succeeded in isolating the active principles of the bulb, and is thus enabled to exclude the poisonous principle and obtain a uniform preparation, which is adapted even for subcutaneous use. The substance called *scillitine*, which has been obtained from the fresh bulbs by ex-

traction with alcohol, is a mixture of the three principles separated by Merck, a fact that accounts for the variability of its action. Dr. Fronmüller, of Furtli, has tested Merck's three preparations of squill on fifty-three cases, and draws the following conclusions concerning them:

1. Scillitoxine in the majority of cases produces pretty free diuresis, but it contains the greater part of the toxic principles of the squill, and hence is not suited for clinical use.

2. Scilline also is not adapted for practical use, because it exists only in minute quantities in the bulb, is very dear, and seems to be inactive unless given in large doses.

3. Scillipierine, dissolved in water and administered hypodermically, has proved to be a diuretic of the first class, second to none other in efficacy. Out of seventeen cases of oliguria, it failed only twice. In twelve of the fifteen successful cases the quantity of urine was doubled and often even more, and in one it was increased sixfold. No symptoms of poisoning were produced, thanks to the separation of the scillitoxine. The only disagreeable effect produced was a more or less intense irritation at the site of the injection; this was absent only in two cases, and in four it was pretty severe. In one case four tablespoonfuls per diem of a two per cent. solution of the scillipierine were given internally without any effect. For the subcutaneous injections a ten per cent. solution was employed in most of the cases; in only one is it stated that a second injection was practised. In two of the cases, the increased excretion of urine was accompanied by thin passages from the bowels.—*Allg. Med. Cent. Zeit.*, Aug. 6, 1879.

BROMINE VAPOR IN THE TREATMENT OF CROUP.—Dr. Netolitzky has employed the treatment of croup recommended by Dr. Schutz three years ago, in nine cases with seven recoveries. He used the following formula: ℞. Bromi puri, Potass. bromidi, ʒā grs. vijss.—xv.; Aque ʒ v.—vij. M. This solution was poured on a small sponge or on cotton, and the patients inhaled the vapor given off by it for five or ten minutes every half-hour. The potash is added to retard the too rapid volatilization of the bromine, which necessitates also a frequent moistening of the sponge or cotton. When there was a tendency to renewal of the exudation, the inhalations were continued for a prolonged period, but weaker solutions were used. Ipecac and other expectorants were given at the same time. One great advantage of these inhalations is the facility with which they can be administered, no special apparatus being required. They do not excite any affection of the respiratory organs, are not specially liable to excite cough, are easily borne, and can be employed at any age. Bromism was not produced in any of the cases. Dr. Netolitzky does not regard the bromine inhalations as a specific for croup, but the results obtained by himself and others have been so favorable, that he feels justified in recommending the method of treatment warmly to the profession.—*Allg. Med. Cent. Zeit.*, August 16, 1879.

SUFFOCATION FROM THE ENTRANCE OF ASCARIDES INTO THE AIR-PASSAGES.—Dr. Fürst reports a case of death from this cause observed in Billroth's clinic, and has found records of 23 other cases since the time of A. Von Haller. In this case the child while under treatment for another affection was suddenly seized with symptoms of suffocation. Tracheotomy was at once performed, but some obstacle prevented the introduction of the catheter, which was used because no canula was at hand. The child died, and after

death a lumbricoid worm, which had in all probability obstructed the larynx, was drawn from the nose.

A similar case was reported last year by P. Donati. A boy, five years of age, while suffering from constipation, vomited a lumbricoid worm; a dose of castor-oil was also vomited without moving the bowels. In the following night the child vomited again, and was then seized with an attack of suffocation in which he died. No history of previous attacks of dyspnea could be obtained. At the autopsy, an ascaris lumbricoides was found sticking, doubled on itself, in the larynx and trachea, entirely obstructing the lumen of the tube. The worm was eight inches long. A second ascaris was found in the larynx, caught in the loop formed by the first, and two more were found in the pharynx and oesophagus.—*Centralblatt für Chirurgie*, July 12th, and Aug. 23d, 1879.

EXTERNAL APPLICATION OF THE BROMIDE OF POTASSIUM.—The good effects obtained from bromide of potassium in all reflex irritations due to teething are well known, but M. Peyraud claims that better results can be obtained from direct local application of the remedy to the gums, than from its internal administration. He uses a mixture of the bromide one part, to honey six or seven parts, with sufficient water to dissolve the salt, and enough alcohol to preserve the mass. This should be gently rubbed on the gums four or five times a day; in cases of diarrhoea caused by dentition, a few drops of Sydenham's laudanum may be added with advantage. The bromide acts as an anæsthetic to the mucous membrane, as a caustic to excoriations, and through its effect on the general nervous system. It quiets immediately the urticaria of dentition, and under its influence those excessively nervous children in whom the eruption of the teeth is irregular and difficult, pass through this period without convulsive phenomena.

M. Peyraud has also used it with success in caries of the teeth and of some of the long bones, and in diphtheria. Carious teeth he fills with powdered bromide, which is retained in its place by a tampon of cotton; the first application calms the pain in about twenty minutes, and the tooth gradually becomes insensible. In caries of the long bones the fistulæ are washed out with a solution of the bromide in glycerine and water. Diphtheritic membranes are powdered with the finely pulverized salt, every two, three or four hours, according to the severity of the case. A cure results in from twenty-four hours to five days, the average being about three to four days.—*Journal de Médecine*, August, 1879.

WORMS IN THE NASAL CAVITY EXPELLED BY MEANS OF CHLOROFORM.—A woman, twenty-nine years of age, was attacked by variola in the ninth month of pregnancy; normal accouchement occurred on the second day of the eruption, the disease following its regular course. During the period of desquamation, a fly entered the nasal cavity and deposited there its eggs, which were soon transformed into larvæ. Fever, violent cephalalgia, and multiplication of the larvæ followed. Insufflations of calomel and injections of salt water were useless. Dr. Garuco then had recourse to inhalations of chloroform, and, at the first trial, seventy larvæ were expelled. This treatment was repeated every day, and completely relieved the patient. Experiments with some of the larvæ showed that, at first, chloroform caused very active movements, after which all movements ceased and complete inertia ensued.—*Gaz. Med. Ital.*, and *La France Médicale*, August 23, 1879.

THE MEDICAL RECORD:

THE MECHANICAL TREATMENT OF POTT'S DISEASE.

I.

FROM the earliest times of which we have any medical history to the present, the treatment of spinal deformities has received the attention of physicians, and yet it seems to be an unsettled question how these cases should be managed. It is true that the pathology of this affection is now well understood, and the indications for its treatment are distinct; yet if one consults the different treatises on this subject, he will be astonished at the divergent views expressed by their authors as to how these indications shall be carried out. There has, we fear, been too much dogmatic writing, special pleading, and claiming of better results than can be obtained by any method of treatment in a disease of the nature of the one we are considering.

It seems to us that a review of the subject of the treatment of spinal deformity may not be out of place at this time. The indications for treatment in angular curvature are to place the parts at absolute rest, to remove pressure from the diseased bone, and at the same time to permit the patient to go about. The bones involved in the disease are so situated that only the posterior portion is accessible for the purpose of any direct support, and fixation can only be obtained indirectly by rendering the whole trunk immovable in either an antero-posterior or a lateral direction. Whatever mechanical device, splint or brace is used must, therefore, encircle the whole body. The scapulae, not being fixed points, are entirely useless for the purpose of support or extension. Any apparatus, therefore, that depends on an axillary crutch to assist in supporting or extending the spine, is constructed on a wrong principle, and will prove a failure so far as the crutch is concerned. The spinal column, with reference to support when it is diseased,

may be divided into two parts, namely, that above and that below the seventh dorsal vertebra. Below that point dependence can be placed in the encircling bandage or brace; while above, support must be provided for the head, so as to keep the parts above from pressing on and irritating the diseased points.

We have mentioned the seventh dorsal as the point above which support for the head should be provided. Dr. Wyeth says the fourth dorsal; but it is necessary that the support should extend considerably above the point of disease in order to obtain fixation, and we think that it is much better to err on the side of supporting too much rather than too little. This is accomplished by either a chin-piece, as in Taylor's brace, or by suspending the head, as done at the Hospital for Ruptured and Crippled, and by Dr. Sayre, and then throwing the part back so as to transfer the weight as much as possible from the bodies of the vertebrae to their transverse processes. We think that all orthopaedic surgeons agree in regard to the above points. The question is, How can this be best accomplished? There has, unfortunately, arisen a personal element in the advocacy of this or that mode of meeting this indication. Dr. A condemns as worse than useless the apparatus advocated by Dr. B. Dr. B considers Dr. A's bandage filthy, etc., while Dr. C thinks that both Dr. A's and B's splints fail fully to meet the indication, but that he has one that is *absolutely* perfect. Patients who, before having it applied, had to be carried on a stretcher, after having it adjusted immediately walked about. The truth is, that *any apparatus or bandage* that gives *good* support to a diseased spinal column is a good spinal brace, no matter how or of what material it is constructed. It would be as foolish to contend that there was only one splint for the treatment of a fractured limb as to confine the treatment of caries of the spine to one pattern of brace.

Spinal supports may be divided into two classes, namely, those made of steel (as Taylor's), and those made of some material that hardens after being applied—as the plaster-of-Paris jacket, the felt splint, or the paper mould. We will mainly refer to the use of the plaster-of-Paris bandage, or jacket, as it is more commonly called, and the steel brace.

Those who use the steel brace claim that it is cleaner, is less liable to get out of order, and meets the indication better than the plaster-of-Paris jacket; while, on the other hand, the advocates of the plaster-of-Paris jacket think that it is easier applied, that it is more comfortable, and that better results are obtained by its use than from any other splint or brace. In discussing this subject, we labor under a great disadvantage in not knowing the full results of treatment. In the case of fractures of the limbs we have an absolute standard to guide us, and statistics can be relied upon. But in Pott's disease there is no fixed

standard, and what one might call a good result may not be recognized as such by another.

At the recent meeting of the American Medical Association, Dr. Sayre presented statistics of the results obtained by him in one hundred and nine cases of spinal disease. We have not seen the paper, only the table, and in the absence of the former, and of any similar tables prepared by others working in the same department, it would be unwise to draw any conclusions. The exhibit is certainly excellent; but in dealing with a subject of this kind we must not forget that a low rate of mortality cannot be entirely attributed to the mode of treatment adopted. The aim is for something beyond the mere saving of life—it is the prevention of deformity, or any further increase of it; and in fact it is upon these elements that the real value of tables of statistics must depend.

It is true that every year or so papers are read before one or more of the medical societies on "my method" of managing cases of Pott's disease, and patients are exhibited illustrating the results obtained; but we have always noticed that they are those that have done remarkably well, and, it is to be feared, are not a fair sample of the general results. There are many, very many, cases that do badly, no matter what mode of treatment has been adopted, and of these we hear nothing. For disease in the lower dorsal and lumbar region, as good support can be obtained by the use of the plaster-of-Paris jacket as with a Taylor's brace. Its drawbacks are that in young children it will get soiled, no matter how much care is taken, and it is liable to chafe, even when put on by those thoroughly skilled in its application, and troublesome eruption on the skin has been frequently seen under the splint—an accident that may occur with any form of apparatus that completely encircles the body.

It is to be feared that its advocates claimed too much for it. Any one who has had much experience in the use of plaster-of-Paris must be aware how liable a splint made of this material is to become loose after a week or so. No matter how tightly it has been fitted, the edges are liable to get soft and crumble, and a new one soon has to be applied. The same difficulty has been experienced with the plaster jacket. It is claimed that when the bandage is properly adjusted it is molded into the intercostal spaces, and that in this way the ribs are fixed. The possibility of accomplishing this while the patient is using his lung has been questioned; and then, if the difficulty were removed, the thick flannel shirt over which the plaster bandages are applied, might tend, by its elasticity, to prevent the accomplishment of this end.

Of course, these remarks apply with equal force to all supports of this character.

THE GROWTH OF STATE MEDICINE.

IN examining the last annual reports of the various city and State Boards of Health, we are struck with

the marked increase in the variety and value of their contents. The contributions cover an unusually wide ground, and show that sanitary science can be brought to bear not only upon social and economical, but even upon literary and artistic matters. At the present rate, indeed, hygienic law and studies will soon interpenetrate every phase and period of a civilized man's existence. The State sanitarians have already struck at the very beginnings of life. They have introduced themselves to the infant, and have mingled with scientific data the uncertain joys that attend his growth. The last Massachusetts Report proposes that the puerperal woman be at once supplied with printed forms upon which to record the physical condition and progress of her offspring. Such a plan, it is stated, has been in existence for some time in certain European cities.

As the future citizen develops, his course is attended with a constantly increased watchfulness—a watchfulness that does not forget the collection of the more abstruse scientific facts. Nearly every State Board has examined the school-houses, and has recommended, or caused to be adopted, properly ventilated rooms. The school-boy is given 250 cubic feet of air, where he used to have 25. His eyes are examined, his shoulders kept back, and the light thrown in from behind. In Boston, the boys and girls have been subjected, in addition, to anthropometrical investigations, and charts are given showing how fast the children grow under the high intellectual tension of that city.

In the report of the Wisconsin Board is a valuable paper upon the proper reading for the young; nor, upon perusal, can we do else than believe that State advice and even State regulation is greatly needed in this direction. The class of literature which includes such works as the Half-Dime Novels—works which have the odor and suggestion of an intellectual emesis—effects in time quite as much physical evil as imperfect sewers. It is evidence of breadth of view and earnest purpose that scientific bodies speak authoritatively for the State on such subjects.

It has from the first been a prominent purpose of State medicine to protect children from the contagious diseases to which they are subject. With each year more perfect methods of prophylaxis have been devised, and their application has been more widely urged. The recommendations for the prevention of scarlet fever and diphtheria issued by some of the boards—and we may refer particularly to those of Massachusetts and Wisconsin—have been valuable additions to medical science. They have been widely circulated, and, as is shown by many letters received in regard to them, they have excited much interest among the people. This has in turn reflected upon the State Boards; it has made them more popular, and the local town and city boards more numerous. In Massachusetts, sixteen of the nineteen cities and three hundred

and one of the three hundred and twenty-five towns have organized local boards of health, and these make regular reports to the central or State Board.

There is, however, no single direction in which sanitary boards have made more important advance than in that of vital statistics. The collection of such information is a comparatively recent undertaking in this country, and, as would naturally be the case, has been attended with much difficulty. A busy and practical people cannot easily be made to see the importance of registering every birth, marriage, and death. Nevertheless, a foothold has been gained, the sentiment is becoming favorable to such registrations, and already even in some of our Western States very full reports come in each year. We have learned even thus soon, through this work, something of the way in which our nation is growing. Some of the facts have an especial interest to medical men. It is shown that the birth-rate among our native-born population in the cities is approximately only 16.74 per thousand, while that of the foreign-born citizens is 35.23 per thousand. This birth-rate for native Americans is even smaller than that of the French in France. Physicians know best perhaps the true "inwardness" of this state of things; and as regards remedy, although clergymen can preach and statesmen legislate, it is the medical profession that can be of the more direct use in educating people to the beauties of a larger domestic circle, or, at least, in discouraging the means for limiting it.

It will be seen that the aims of the health boards are very far from being confined to preventing the invasion of infectious diseases. The boards are becoming educators of the people to cleaner and better domestic life; they preach against vice, intemperance, and licentiousness, as well as dirt. They are giving valuable advice to architects, book-makers, alienists, as well as to political economists and legislators. And last, but not least, to physicians; in one instance, the creation of a State Board—that of Illinois—has driven fourteen hundred charlatans from its borders.

It cannot be long before such organizations are appreciated everywhere at their full value, and become recognized as most important branches in the administrative service of a State.

INTRA-UTERINE MEDICATION.

We are pleased to give our readers in this number a very interesting summary of a discussion upon the above subject, held in the Obstetric Section of the British Medical Association, and also in the American Gynecological Society, at its annual meeting, lately held in the city of Baltimore. It is an important subject, and worthy of careful consideration by every general practitioner of medicine. The majority of those who participated in the discussion, both in this country and in the British Medical Association, favor the use of this means of treating uterine diseases; yet,

as will be seen, some of the most eminent in the profession regard it as a measure that possesses only doubtful value as a general rule of practice. Upon one point there is an almost unanimous opinion—and that is, that intra-uterine injections are dangerous, especially so in the non-puerperal uterus. An essential precaution, whether used in the puerperal or non-puerperal uterus, is that there shall be sufficient dilatation of the internal os and the cervix to allow of free return of the fluid. In a subsequent number we shall be able to give our readers a more extended report of the discussion upon this and other subjects which took place in the American Gynecological Society.

Reports of Societies.

BRITISH MEDICAL ASSOCIATION.

SECTION C—OBSTETRIC MEDICINE.

Wednesday, August 6, 1879.

DR. GEORGE H. KIDD, OF DUBLIN, PRESIDENT, IN THE CHAIR.

INTRA-UTERINE MEDICATION.

THE discussion upon the above subject was opened by DR. W. S. PLAYFAIR, who took the position that, like all powerful means of cure, it was capable of doing much harm when injudiciously used, but that in properly selected cases there were few methods of treatment possessing greater efficacy. So far from rendering the woman sterile, as had been claimed by some, it had, in properly selected cases, often had the effect of removing acquired sterility.

DR. LOMBE ATHILL, of Dublin, held that the inner surface of the body was especially prone to disease, and to effect a cure the part involved should be specially treated. He placed the symptoms indicating the necessity for intra-uterine medication under the following heads, excluding all tumors and conditions arising from anæmia: 1, derangement of menstrual function, especially dysmenorrhœa and hæmorrhagia; 2, uterine catarrh; 3, pain, especially that caused by pressing the point of the sound against the fundus. He objected to intra-uterine injections, and relied upon fluids or ointments applied by means of cotton and an applicator. The agents he employed were carbolic acid in solution, tincture of iodine, iodized phenol, nitric acid, solid nitrate of silver, zinc points, and crayons of iodoform. Carbolic acid he employed most commonly, because it was safe and efficient; iodized phenol, when a more powerful agent was required, but still it was inferior to nitric acid, which should always be applied to the intra-uterine surface through a tube or canula, and the woman should be confined to her bed for one day at least after the acid had been applied. He feared no unpleasant results when those precautions were adopted.

DR. ROBERT BATTEV, of Rome, Ga., U. S. A., presented the advantages which the iodized phenol possessed for intra-uterine medication. A solution of one part of iodine in four of liquefied carbolic acid was a strength that had proved satisfactory for ordinary intra-uterine medication. One part by weight

of iodine to two parts of carbolic acid made a concentrated solution which could be employed to supplement the cure in the treatment of various conditions, especially cancer.

DR. E. J. TILT, of London, restricted his remarks to intra-uterine medication for the cure of chronic inflammation of the mucous membrane of the body of the uterus. He laid special stress on the fact that internal metritis was present in all bad cases of inflammation of the cervix, and asserted that there would be but little need of intra-uterine medication if the cervical canal was kept free of disease. There were certain conditions, however, in which intra-uterine medication was justifiable, such as internal metritis, independent of ovariitis, but complicated by menorrhagia and dysmenorrhœa independent of ovariitis, and endangering reason and life; membranous dysmenorrhœa; habitual abortion independent of syphilis and ovariitis, and apparently dependent on some morbid condition of the mucous membrane of the uterus; the dangerous reaction in the system, caused by internal metritis, independent of the amount of purulent discharge; loss of blood resisting all remedies, and threatening life. He recommended undiluted injections of tincture of iodine in cases of dangerous flooding from internal metritis, and in membranous dysmenorrhœa. Nitrate of silver in solution was apt to produce severe pelvic disease, and was discarded. He preferred to place five or six grains of solid nitrate of silver in the uterus, but was ready to welcome a better plan than that.

DR. GALLARD, of Paris, believed that in internal metritis and the various disorders that attack the interior of the uterus, cauterizations were of the first importance, and, to be serviceable to the fullest extent, they should be applied in the fluid rather than in the solid form. He referred to the beneficial use of the curette in cases of "vegetation of the mucous membrane" of the uterus.

DR. ROBERT BARNES, of London, thought that Dr. Tilt represented what used to be the accepted mode of treatment, but which had long ago been left behind. The method of intra-uterine medication that he adopted—for he was an advocate of the plan—was that of "swabbing" the mucous membrane with cotton-wool dipped in medicated solutions. Of those solutions he had used iodine and carbolic acid quite extensively, and thought that each possessed its own advantages. He thought the application of iodine was the most ready way of curing all uterine affections arising from syphilis. He further believed that if the surgeon wished to do any good in certain cases, he must resort to the intra-uterine use of remedies already mentioned.

DR. MACAN, of Dublin, thought that different treatment was required for the nulliparous and the multiparous classes. In the nulliparous the disease of the uterus, in very many cases, arose from closure of the external os. Measures must be first taken to remove that condition, and with its removal the trouble above generally subsided.

DR. WALLACE, of Liverpool, had been struck by the repeated statement made by patients that they had been under treatment for years, being subjected to intra-uterine medication without any alleviation of their suffering. For uterine catarrh, although dependent on many conditions, he had great faith in vaginal douches of hot water, 80° to 120° F., and from two to four gallons, and stated that he had effected a complete cure without any intra-uterine medication.

DR. MALINS, of Birmingham, concurred in the treat-

ment recommended by Dr. Wallace. Experience had taught him that intra-uterine medication was not required as much as had been claimed by many. He believed that in the multiparous uterus hygienic treatment was very important, and the best that could be adopted. He did not dispute that it was sometimes necessary to resort to intra-uterine medication, especially in the cases mentioned by Dr. Athill.

DR. LOMBE ATHILL, of Dublin, agreed with Dr. Macan and Dr. Tilt, that incision of the cervix was sometimes essentially necessary. When there was chronic endometritis he regarded it as impossible to cure the patient without incision of the cervix. He looked upon the vaginal douche as of the greatest value, and employed it freely in the Rotunda Hospital; but it was by no means sufficient in all cases.

DR. WM. H. BYFORD, of Chicago, Ill., U. S. A., believed that, in very many instances, intra-uterine medication could be adopted with safety. When he proposed to resort to the use of strong agents, such as nitric acid, he put his patient under a course of preparatory treatment: kept her quiet beforehand, and in bed two or three days after the application. He did not resort to this form of treatment until several days had elapsed after the occurrence of the menstrual period.

He thought that the condition which usually called for this method of treatment was general hyperæmia and more or less hyperplasia of all the tissues of the uterus. Menorrhagia, metrorrhagia, and leucorrhœa, one or all, were symptoms found in that condition. The remedies that could be used with the most benefit, whether hemorrhage was present or not, were vascular nervous uterine stimulants. He had not for many years injected medicine into the uterine cavity, because he thought it was attended with risk to life, and certainly it was painful.

DR. HENRY BENNET, of London, thought it of the utmost importance to secure a good general condition of the patient and the integrity of the surrounding organs before resorting to intra-uterine medication.

THE AMERICAN GYNECOLOGICAL SOCIETY.

Annual Meeting, September 17, 1879.

DR. T. GAILLARD THOMAS, OF NEW YORK, PRESIDENT,
IN THE CHAIR.

INTRA-UTERINE MEDICATION.

THE above subject being before the Society for discussion, DR. JAMES P. WHITE, of Buffalo, remarked that in making application of fluid substances to the internal surface of the uterus, the most simple method would appear to be by injections, and that method was still advised. The experienced practitioner, however, seldom injected medicinal agents into the cavity of the uterus. He recommended the use of applicators in intra-uterine medication—long probe and cotton. He said that the uterus could not be injected with safety, but that nitric acid could be spread over the surface of its mucous membrane without danger.
